Independence.—The relative calm of Spanish Nicaragua was succeeded by more than four decades of confusion and turbulence. Violence began in Dec. 1811 when the governing intendant was deposed in a revolution inspired by earlier struggles in Mexico and El Salvador. Ill feeling developed between León and Granada when León returned early to the royalist cause and Granada bore the brunt of the punishment for disobedience. León declared independence from Guatemala on Sept. 28, 1821 (following Guatemala's act of independence from Spain, Sept. 15), but Granada chose to stay with Guatemala. Both accepted union with Mexico (1822–1823), but then fought until 1826, when Nicaragua was organized as a state in the Central American federation. Dissension remained the order of the day until 1838, when Nicaragua left the federation, and then was resumed as part of the general isthmian struggle between Liberals and Conservatives, León being the stronghold of the former, Granada of the latter. Meantime in the east relations between the "king" of the Miskito peoples and the British government were strengthened to the point where English officials were again living in Bluefields. San Juan del Norte was seized by the British in 1848.

The discovery of gold in California brought attention to Nicaragua's strategic position between the oceans. The Accessory Transit company of Cornelius Vanderbilt, which carried passengers by steamship and carriage from San Juan del Norte to the Pacific, began operations in 1852. Adventurer William Walker (*q.v.*) from Tennessee, invited to assist the Liberals in warfare in 1855, brought new excitement to Nicaragua. By 1856 Walker had made himself president of the country. In 1857 he was routed through the joint efforts of the five Central American republics and the Accessory Transit company.

Tomás Martínez, who assumed the Nicaraguan presidency in 1857 and held it for ten years, was the first of a line of Conservative chiefs of state who ruled until 1893. Under them Nicaragua enjoyed relative peace, though with little democracy. The capital was placed in Managua as a compromise between Granada and León. The first railroads were built, agriculture was revived to some extent and a treaty with Great Britain (1860) provided for the nominal reincorporation of the eastern coast with the nation, under the form of an autonomous reservation. José Santos Zelaya, Liberal president from 1893 to 1909, established real Nicaraguan jurisdiction over the Miskito peoples for the first time, and increased his power to the point where he could interfere in the affairs of Honduras and El Salvador. Two great writers sprang from Nicaragua during this quieter half century. Rubén Darío (*q.v.*) became recognized as one of Latin America's greatest poets. Salvador Mendieta (1879–1958) was a distinguished diagnostician of his own region's ills, who dedicated his life to the rebuilding of the Central American union. Both men were critical of the new interest taken in isthmian affairs by the United States once the decision was made to build the Panama canal.

United States Intervention.—A new era in Nicaraguan history involved intervention by forces of the United States government. It may be said to have begun when Philander C. Knox, secretary of state for President Taft, became angered at the execution of two U.S. citizens who had participated in a revolution against Zelaya. When Zelaya resigned late in 1909 the United States refused to recognize his successor, José Madriz. In 1910 its naval forces prevented government occupation of Bluefields, the revolutionary headquarters, an act leading directly to the success of the revolution. When new civil war broke out in 1912 U.S. forces took a direct hand in support of Adolfo Díaz, president from 1911 to 1917. A hundred marines stationed at the United States embassy also helped to maintain the peace under Emiliano

Chamorro Vargas (1917–20) and his nephew successor. United States bankers meanwhile managed the Nicaraguan customs collections, the national bank and railway. The Bryan-Chamorro treaty of 1916 gave Nicaragua $3,000,000 in exchange for the U.S. right to build an interoceanic canal and to establish naval bases on the Gulf of Fonseca and Corn Islands.

Withdrawal of the marine guard (1925) led to new complications. Rebellion by Chamorro Vargas against a new administration brought Díaz back as a "compromise" president (1926–28), reinforced by 2,000 United States marines. Díaz was opposed in warfare (1927) by Juan Bautista Sacasa, Gen. José María Moncada, Gen. César Augusto Sandino and others. Though elections in 1928 under U.S. auspices brought Moncada to the presidency, followed in 1933 by Sacasa, Sandino fought on against both his old friends and the marines and came to typify for many Latin Americans the cause of resistance against *yanqui* imperialism.

Later Developments.—Sacasa's inauguration (Jan. 1, 1933) terminated the stay of the U.S. marines. Within the year Sandino made peace with his government. Prominent on the scene by then were the Nicaraguan national guard, carefully trained by the marines before their withdrawal, and its commander, Gen. Anastasio Somoza, nephew of the president. In Feb. 1934, just after he had dined with Sacasa, Sandino was assassinated by members of the national guard with Somoza's approval. Against Sacasa's wishes Somoza decided he would next have the presidency, though both his position and his family relationship made him ineligible. Constitutional problems were "solved" by the deposition of Sacasa (June 1936) and a temporary relinquishment of the guard command. Somoza became president Jan. 1, 1937, backed by a coalition of segments of the old parties. Leonardo Argüello, his defeated opponent, had support from both of the traditional parties.

One man then controlled Nicaragua for 20 years. A new eight-year term commenced March 30, 1939, under a revised constitution which increased the power of both president and national guard. In 1945, after *caudillos* had been removed from office in El Salvador and Guatemala, Somoza announced that the guard would remain loyal to the winner of the next elections. When Argüello won those elections and took office May 1, 1947, Somoza (still at the head of the guard) had him ousted within a month. Somoza's uncle Víctor Manuel Román y Reyes, chosen by the party organization to succeed, was president until he died May 6, 1950. Somoza then reassumed the position, and was elected to another six-year term beginning May 1, 1951. A pre-election agreement with Emiliano Chamorro Vargas guaranteed the opposition a minority voice in the new congress.

The development of a small gold mining industry by foreign capital in the 1930s gave the nation its first sizable export commodity. Strict economic dictatorship was coupled after 1941 with wartime co-operation with the United States, which brought material benefits in its wake. After the war an aura of prosperity developed with new large plantings of coffee and cotton for export (subsistence crops suffered badly for a time), establishment of textile and food processing industries and the organization in 1953 of a private shipping line, Marina Mercante Nicaragüense (Mamenic). But observers noted the extent to which Somoza family holdings bound the economy together, while the people at large benefited little from the rise in national income.

The constitution of 1950, written by agreement between Somoza and Chamorro Vargas, provided that no president of Nicaragua might be re-elected and that no person might be elected to the office who had exercised the presidency temporarily during the last six months of the term or who was a relative of the president. Despite these provisions, it became clear as Somoza's term progressed that he intended to succeed himself. A serious attempt to assassinate Somoza failed in 1954. On Sept. 21, 1956, a few hours after he was nominated by his Nationalist Liberal party for six more years in office, he was shot by Rigoberto López Pérez, who gave his own life for the deed. Somoza died eight days later. The death of Somoza did not end the rule of his family. All the constitutional prohibitions having been repealed by the Nationalist Liberal majority in congress, 34-year-old Luis Somoza Debayle was given his father's position at once, and then was nominated in his father's stead and chosen president for the term 1957–63. A younger brother, Anastasio Somoza Debayle, remained head of the national guard. An unsuccessful attempt to unseat this second generation was made in 1959 by a group led by Enrique Lacayo Farfán, consisting of opposition Conservatives and Independent Liberals. During this time the country found itself united on one matter, the revival of an old boundary dispute with Honduras, but withdrew its forces from the disputed territory after a 1960 decision of the International Court of Justice favouring Honduras.

The constitutional provisions concerning the presidential succession were reinstituted in 1959, and Luis Somoza Debayle promised free elections at the end of his term. He did not, however agree to the demand of the Traditionalist Conservatives and Independent Liberals for supervision of the elections by foreign and neutral observers. René Schick Gutiérrez, a constitutionally eligible close friend of the Somozas, then won a four-year term in the 1963 election in which these other parties refused to participate. Though Schick showed some spark of independence in his term which began May 1, 1963, there was little doubt that Anastasio Somoza Debayle, still the head of the national guard, expected to campaign for the presidency in 1967. Schick died in office in Aug. 1966, and congress elected Lorenzo Guerrero, one of the three vice-presidents and also a Nationalist Liberal, to fill out the term.

(F. D. P.)

POPULATION

Number and Distribution.—A census taken in 1963 showed Nicaragua to have a total of 1,535,588 inhabitants, or the equivalent of 30.6 persons for each of the 50,193 sq.mi. of national territory (*see* Table). By 1965 the total population was estimated to have risen to 1,620,000, and after that time it was expected to continue to increase rapidly by about 50,000 per year. A very high birth rate (probably at least 45 per 1,000 population), coupled with a death rate of less than 20, was responsible for this increase.

Nicaragua's population, which is largely agricultural, is heavily concentrated in the western one-third of the country, especially in the small section near the Pacific coast that extends from the city of Chinandega on the north to the city of Granada and Lake Nicaragua on the south. According to the 1963 census 41.1% of the population resided in urban centres, of which Managua (*q.v.*), the capital with a population of about 240,000, was the largest. León and Granada (*qq.v.*), with populations (1963) of 45,048 and 28,507, respectively, are the next largest cities in the republic.

Number of Inhabitants and Density of Population in Nicaragua by Departments, 1963

Departments	Area (sq.mi.)	Population	Persons per sq.mi.
Total	50,193*	1,535,588	30.6
Boaco	1,924	71,615	37.2
Carazo	398	65,888	165.5
Chinandega	1,800	128,624	71.5
Chontales	1,910	75,575	39.6
Estelí	849	69,257	81.6
Granada	372	65,643	176.5
Jinotega	3,697	76,935	20.8
León	2,021	150,051	74.2
Madriz	679	50,229	74.0
Managua	1,403	318,826	227.2
Masaya	210	76,580	364.7
Matagalpa	2,623	171,465	65.4
Nueva Segovia	1,290	45,900	35.6
Río San Juan	2,876	15,676	5.5
Rivas	830	64,361	77.5
Zelaya	22,816	88,963	3.9

*Includes lakes, lagoons, rivers, etc., not included in the area of the departments.

Composition.—Approximately 20% of Nicaragua's population is white and 10% Negro, with mestizos, *zambos* (Indian-Negroes) and mulattoes making up the remainder. Practically no full-blooded Indians remain and mestizos greatly predominate.

Because of the high birth rate and the comparatively high death rate that has prevailed throughout the 20th century, Nicaragua's population is highly concentrated in the younger ages, as is evidenced by the fact that in 1950, 44.3% were under 15 years of

age, 53.9% in the age group 15–64 and only 2.8% were 65 and over.

Spanish is the mother tongue of the Nicaraguan people, although many members of the upper and middle classes have a familiarity with English as well. Although the various tongues once spoken by the aboriginal inhabitants have almost disappeared as languages, they have left their impress upon Nicaragua's place names, and many designations of things have been incorporated into the Spanish used in this part of the hemisphere.

The vast majority of the people of Nicaragua are of the Roman Catholic faith, although a sprinkling of Protestants of various denominations and small groups of those professing Judaism are found in the principal cities. In the religion of the common people few aboriginal beliefs and practices survive. (T. L. Sh.)

ADMINISTRATION AND SOCIAL CONDITIONS

Government.—Nicaragua has had nine constitutions: 1838, 1854, 1858, 1893 (amended 1896), 1905, 1911, 1939, 1948 and 1950 (as amended). The last, in force since Nov. 1, 1950, provides for separation of powers (legislative, executive and judicial branches) with strong, centralized, executive government. Nicaragua is one of the few Latin-American countries which has not attempted to control centralized, executive power through a semi-parliamentary system. Although the president is theoretically elected for a four-year term (six years until May 1, 1963) and is ineligible for immediate re-election, Gen. Anastasio Somoza, the most distinguished *caudillo* or leader of the 20th century, dominated government from the 1930s until his assassination in Sept. 1956. Congress is empowered to appoint a *designado* to take the president's place when it is necessary to fill out an unexpired term

Nicaragua is the only country in Central America with a bicameral legislature. It is also the smallest bicameral legislature in all of Latin America. The senate of 16 members (plus former presidents, who hold senatorship for life, and the defeated runner-up in the presidential contest, who receives a term of six years) and the chamber of deputies of 54 (one to every 30,000 of population, with each department guaranteed at least one representative) are elected directly for 4 years. The legislature meets only two months each year.

With opposition practically eliminated during several decades of mid-20th century, the legislature was almost completely subservient to the executive. The legislature can and does delegate broad authority to the president to legislate by decree, even in economic fields. Local government is controlled by the central government. The country is divided into 16 departments and one *comarca* (national district) each with a political head, appointed by the president, nominally in control. The president governs Managua, the capital, through a minister. The supreme court of seven members, elected by congress, has authority to introduce bills in the legislature. Although Nicaragua, like Costa Rica, does not have an army, it does have a national guard of about 7,500 men, originally trained by the United States marines.

Education and Social Welfare.—Although about 18% of the national budget is usually devoted to education, probably more than 65% of the people are illiterate. Schools are unavailable in many of the rural areas. Furthermore the average length of primary school enrollment is two to three years, a period which is considered inadequate preparation for the duties of citizenship. The National University of Nicaragua is in León, with branches in Managua and Granada. Legislation limiting the total number of hours to be worked per year and establishing maximum daily and weekly working hours was introduced in 1945. The 1950 constitution contains many welfare guarantees, only some of which have been made effective. (W. S. Ss.)

THE ECONOMY

Production.—Nicaraguan economy is predominantly agricultural; the chief crops are cotton, coffee, sesame, sugar, rice, corn and beans. Sorghum, cacao, yucca, tobacco, plantains and a variety of other fruits and vegetables are also produced on a relatively smaller scale for the local market. Exports of cotton and coffee account for roughly 75% of total export value. The importance of bananas has fallen markedly because of sigatoka disease. There are possibilities for greater agricultural development since only about one-fifth of the arable land is used for crop production. Cattle raising is significant for dairy produce in the west and beef in the eastern plains. Gold mining has been an important activity since precolonial days and the principal mines are owned by U.S. and Canadian concessionaires.

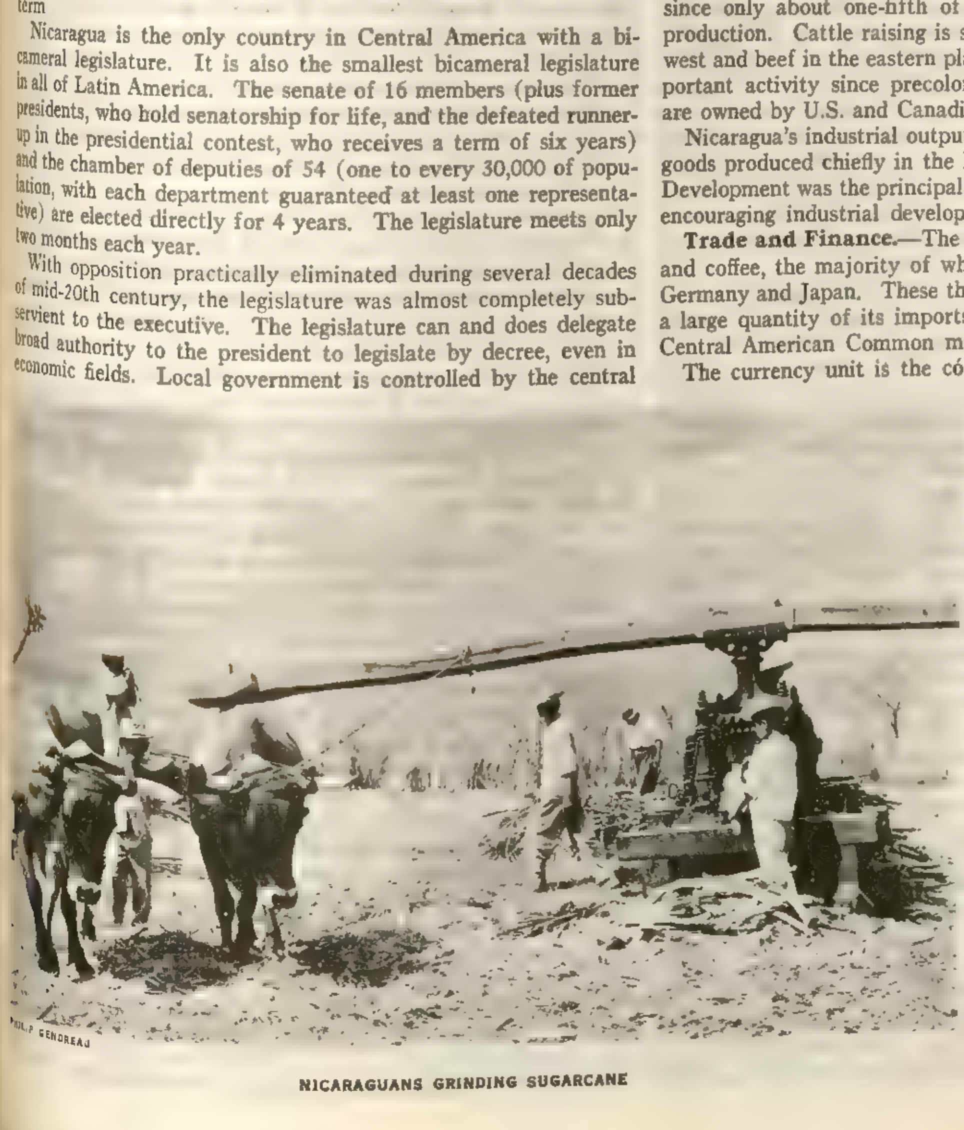
Nicaragua's industrial output consists of a variety of consumer goods produced chiefly in the homes. The Institute of National Development was the principal government agency responsible for encouraging industrial development.

Trade and Finance.—The nation's leading exports are cotton and coffee, the majority of which are shipped to the U.S., West Germany and Japan. These three nations furnish Nicaragua with a large quantity of its imports. Nicaragua is a member of the Central American Common market.

The currency unit is the córdoba. A single exchange rate of seven córdobas to the U.S. dollar was established in 1955 and applied to all imports. The Nicaraguan banking system has been dominated by the state-owned National Bank of Nicaragua. A new Central bank, however, was established in 1961.

The main source of government revenue is through indirect taxation—import duties and surcharges, export taxes on coffee and sales taxes on liquor, cigarettes and other consumer items.

Transport and Communications.—The Pan-American highway is passable in all weather from the Honduran border to the Costa Rican border. However, it is unpaved for nearly half this distance. A railroad runs from Corinto on the Pacific coast to Granada and Diriamba. The chief ports are Corinto, San Juan del Sur and Puerto Somoza, all on the Pacific coast. Managua is on the north-south air route from



NICARAGUANS GRINDING SUGARCANE

the U.S. to Panama and is linked by air to the capitals of other Central American republics. *See* also references under "Nicaragua" in the Index.

Tweedy, *This is Nicaragua* (1953); M. G. Palmer, *Through Unknown Nicaragua* (1946). Current history and statistics are summarized annually in the *Britannica Book of the Year*. (W. C. Gn.)

NICARAGUA, LAKE, the largest of several fresh-water lakes in southwestern Nicaragua and the largest lake in Central America, is nearly 110 mi. long and 45 mi. wide at its widest place, with an area of 3,089 sq.mi. In the lake are many picturesque islands, the largest of which is Ometepe, bordered by two high volcanic peaks. The lake has long been important for fishing, sailing, swimming and in local transportation, steamships having operated on it since 1882. The lake and San Juan river have long been discussed as a possible canal route between the Caribbean sea and the Pacific ocean. (C. F. J.)

NICCOLITE, a mineral consisting of nickel arsenide, containing 43.9% nickel. It usually occurs as compact masses of a pale copper-red colour, with metallic lustre on the uneven, fractured surfaces. It is opaque and brittle, and the streak is brownish black. It occurs with ores of cobalt, silver and copper at Annaberg and Schneeberg in Saxony, Ger., at Cobalt, Ont., and other localities. (*See* Nickel.) The formula is NiAs. Crystals are hexagonal, but are rare and indistinct. The specific gravity is 7.5 and the hardness 5.5.

NICE (Italian Nizza), a port and resort city of France, capital of the *département* of Alpes-Maritimes, situated at the mouth of the Paillon river at the northern end of the Baie des Anges, 420 mi. (676 km.) S.E. of Paris. Pop. (1962) 278,714. Beautifully situated and with an agreeable climate, Nice is the leading resort city of the Côte d'Azur, or French Riviera. It has excellent communications by rail, road and sea, and its airport is the second busiest in France. The entrance to the outer port is 300 ft. wide, that to the inner 220 ft. The area of the harbour is about eight acres, and it can be used by vessels drawing up to 23 ft. Nice is an episcopal see (first mentioned at the end of the 4th century) under the archbishop of Aix. It is the seat of a prefect, of tribunals and of a board of trade arbitrators.

The historical nucleus of the town is an isolated limestone hill, running back for some distance from the shore and formerly crowned by a castle (destroyed 1706). The old town stretches along the western base of the hill; the 18th-century town, farther west, slopes gently toward the Paillon; to the northeast and north and west beyond the river lies the modern city. East of the hill the commercial quarter surrounds the port. The whole frontage of Nice is composed of fine embankments, notably the 4-mi.-long Promenade des Anglais, begun in 1822–24 at the expense of the English colony and having two 33-ft.-wide carriageways separated by banks of flowers. The course of the Paillon also is embanked on both sides. Nice has a Roman Catholic cathedral, Ste. Réparate, of the 17th century, restored in 1901; a Russian cathedral (with a richly decorated interior) and church; two synagogues; two Anglican and American chapels; and a Greek church. An astronomical and meteorological observatory is located on Mont Gros. At the Centre Universitaire Méditerranéen (founded in 1933, first director Paul Valéry) French lessons are given for foreign students. The city has several libraries, museums and *lycées*, as well as many theatres, an opera house, three casinos and an open-air theatre. During its famous carnival, beginning on the second Saturday before Shrove Tuesday, Nice becomes the capital of a short-lived kingdom of pleasure; battles of flowers and a *veglione* (party) at the municipal casino add to its gaiety. Carnival is only one of several festivals. Other attractions include automobile, bicycle and yacht races, as well as canoeing, pedalboating, motorboating and skin diving. The beaches are shingle. Summer visitors outnumber those in winter by about three to one.

A mile northeast of the city centre is the ancient episcopal town of Cimiez, with majestic ruins of a Roman amphitheatre of the 1st century A.D., built to seat 6,000 and surrounded by splendid villas and the Regina palace, where Queen Victoria wintered during 1895–99. From east to west Nice is ringed by beautiful districts: Carabacel, St. Étienne, St. Philippe and Les Baumettes. East of the port lie Mont Boron, Riquier and St. Roch.

Though catering for tourists is the leading commercial activity of Nice, it also has some industrial establishments. These include distilleries and oilworks and factories producing perfume, furniture and woodwork, confectioneries, soap, silk goods, straw hats, rubber goods, metal goods and tobacco. Besides the vine, the trees cultivated principally in the neighbourhood are olive, orange, mulberry and carob. Staple exports are olive oil, agricultural produce, fruits and flowers. Trade of the port is mainly coastal.

History.—Nice (Nicaea) was founded about 2,000 years ago by the Phocaeans of Marseilles and was named in honour of a victory (*nikē*) over the neighbouring Ligurians. It soon became a busy trading station, but had a rival in the town of Cemenelum, in existence till the time of the Lombard invasions, the ruins of which are at Cimiez. In the 7th century Nice joined the Genoese league formed by the towns of Liguria. In 729 it repulsed the Saracens; but in 859 and 880 they pillaged and burned it, and for most of the 10th century remained masters of the surrounding country. As an ally of Pisa, Nice was the enemy of Genoa, and both the king of France and the emperor endeavoured to subjugate it; but it maintained its liberties. In the course of the 13th and 14th centuries it fell more than once into the hands of the counts of Provence; and at length in 1388 it placed itself under the protection of the counts of Savoy. The maritime strength of Nice rapidly increased till it was able to cope with the Barbary pirates; the fortifications were largely extended and the roads to the city improved.

During the struggle between Francis I and Charles V great damage was caused by the passage of the armies invading Provence; pestilence and famine raged in the city for several years. In 1543 Nice was attacked by the united forces of Francis I and Barbarossa; the inhabitants were ultimately compelled to surrender, and Barbarossa pillaged the city and carried off 2,500 captives. Pestilence appeared again in 1550 and 1580. In 1600 Nice was taken by the duc de Guise.

By opening the ports of the countship to all nations, and proclaiming full freedom of trade, Charles Emmanuel in 1626 gave a great stimulus to the city. Captured by Catinat in 1691, Nice was restored to Savoy in 1696, but it was again besieged by the French in 1705, and in 1706 its castle and ramparts were demolished. The treaty of Utrecht in 1713 gave the city back to Savoy, and in the peaceful years which followed the "new town" was built. From 1744 till the peace of Aix-la-Chapelle (1748) the French and Spaniards were again in possession. In 1775 the king of Sardinia destroyed all that remained of the ancient liberties of the commune. Conquered in 1792 by the armies of the French Republic, the county of Nice continued to be part of France till 1814; but after that date it reverted to Sardinia. By a treaty concluded in 1860 between the Sardinian king and Napoleon III it was again transferred to France. (A. G. Gr.)

NICEPHORUS, SAINT (Nicephorus Patriarcha) (c. 758–c. 829), Byzantine theologian, historian and patriarch of Constantinople (806–815), whose historical works consist of a useful short history (***Breviarium***) from 602 to 769 and a chronological list from the Creation to his death. Like his father Theodorus he opposed the policy of the iconoclasts. He held office in the imperial secretariat at the time of the Council of Nicaea when the use of icons was restored. For some unknown reason he retired to a monastery on the Bosporus, although he was not a monk. He was then appointed director of the largest poorhouse in Constantinople and in 806 succeeded Tarasius as patriarch of Constantinople. In 815 he was deposed by the iconoclast Leo V and he died in exile in 828 or 829 and was later canonized by the Orthodox Church. His theological works (some unedited) demonstrate the use of new scholastic methods in defense of the icons.

Bibliography.—Nicephorus' works were published by J. P. Migne in *Patrologia Graeca*, vol. 100 (1865) and edited by L. Dindorf and I. Bekker in *Corpus script. Byz. hist.*, vii (1829–37). Critical edition of historical works by C. de Boor (1880). Full bibliography in P

Alexander, *The Patriarch Nicephorus of Constantinople* (1958). *See* also G. Moravcsik, *Byzantinoturcica*, vol. i, pp. 456–459, 2nd ed. (1958). (J. M. Hy.)

NICEPHORUS, the name of three Byzantine emperors.

NICEPHORUS I (d. 811), Byzantine emperor from 802 to 811, a native of Seleucia in Pisidia, became a high financial official (logothete) under the empress Irene. When officials and army officers rose against Irene's inefficient rule, Nicephorus was acclaimed emperor and the empress was sent to a nunnery. Nicephorus' religious policy was orthodox and he allowed the cult of icons, but he was not favoured by ecclesiastical extremists such as Theodore Studites because he tended to assert his authority over the church, and in particular he appointed a learned layman, Nicephorus, as patriarch of Constantinople. He practised strict economy and strengthened military and naval defenses, both by improved methods of recruitment and by enforced colonization of vital areas, but his rigorous methods involved him in considerable unpopularity. In 803 and 810 he made a treaty with Charlemagne, by which Venice, Istria, the Dalmatian coast and south Italy were assigned to the east, while Rome, Ravenna and the Pentapolis were included in the western realm. By withholding the tribute which Irene had agreed to pay to Harun al-Rashid, Nicephorus committed himself to a war with the Muslims. Compelled by the disloyalty of his general Bardanes, he had to take the field himself; he sustained a severe defeat at Crasus in Phrygia (805) and obtained peace only on condition of paying a yearly contribution of 30,000 gold pieces. By the death of Harun in 809 Nicephorus was left free to deal with the Bulgarian king Krum, who was harassing his northern frontiers. In 811 Nicephorus invaded Bulgaria and drove Krum to ask for terms. But he rejected these overtures and in his attempt to crush the Bulgars he was caught in the mountains and killed together with most of his army on July 26.

NICEPHORUS II PHOCAS (*c.* 912–969), Byzantine emperor from 963 to 969, belonged to a Cappadocian family which had produced several distinguished generals. Under Constantine VII he became commander on the eastern frontier. In 960 he led an expedition to Crete and by 961 had gained the island from the Arabs. In the campaigns of 962–963 he forced his way through Cilicia to Syria and captured Aleppo, but made no permanent conquests. On the death of Romanus II he was proclaimed emperor at Caesarea by the eastern troops, and was soon after acknowledged at Constantinople as co-emperor and guardian of Basil II and Constantine VIII, the young sons of Romanus. He married the empress, the notorious Theophano. In 964–966 he conquered Cilicia and again overran Mesopotamia and northern Syria, while the patrician Nicetas recovered Cyprus. In 968 he reduced most of the fortresses in Syria, and after the fall of Antioch and Aleppo (969), which were recaptured by his lieutenants, secured his conquests by a peace. On the northern frontier he refused to pay tribute to the Bulgars, and instigated the Russians under Svyatoslav to attack them, though only to find that he had introduced a dangerously powerful ally into the Balkans. In the west Nicephorus renounced his tribute to the Fatimid caliphs, and sent an expedition to Sicily under Nicetas (964–965), but was forced by defeats on land and sea to evacuate the island. In 967 he made peace with the Muslims of Kairouan in Tunisia and turned to defend himself against Otto I of Germany, who was establishing his authority in Italy, and indeed wished for a marriage alliance with the imperial family which Nicephorus refused. Owing to the care which he lavished on the army, Nicephorus was compelled to exercise rigid economy in other departments. He was a member of the Asian landed aristocracy and favoured this class at the expense of the small farmers. Very ascetic in outlook, he tried to prevent monasteries from acquiring further wealth. By his heavy taxation he forfeited his popularity; he was assassinated in his palace bedroom on the night of Dec. 10–11, 969, by another successful general, the magnate John Tzimisces.

NICEPHORUS III BOTANEIATES, Byzantine emperor from 1078 to 1081, belonged to the military aristocracy of Asia Minor and was related to the powerful Phocas family. As the commander (*strategos*) of the Anatolikon theme he led his army against the feeble Michael VII Ducas. With some support from the Seljuk ruler Suleiman in Asia Minor, he was proclaimed emperor by his troops and entered Constantinople in March 1078. His imperial claim was ratified by the aristocracy and clergy of the capital who had already deposed Michael VII. Nicephorus thus forestalled the *dux* of Dyrrachium, Nicephorus Bryennius, the rival claimant for the throne, though he subsequently had to face another rival in Asia Minor, Nicephorus Melissenus, as well as Turks. But he failed to maintain his position in face of the brilliant young Alexius Comnenus, and on April 4, 1081, he abdicated and entered a monastery.

NICHIREN (ZENSHŌBŌ RENCHŌ) (1222–1282), saint and prophet, founder of the Nichiren sects, the most fanatical in Japanese Buddhism, which, with its offshoots, had about 10,000,000 followers in the 1960s. Of humble birth, Nichiren renounced the world in his 12th year and entered a monastery. After years of ardent study on Mt. Hiei and at Nara he reached the conviction that the Lotus Sutra (Saddharma Pundarika; *see* BUDDHISM: *Literature of the Mahayana*) forms the kernel, the quintessence, of Buddha's teaching, a conviction he announced publicly in 1253.

Nichiren was at the same time passionate and tender-hearted, and these two sides of his character presented themselves in turn during the chequered course of his prophetic life. His first warning was given in 1260 in a treatise, the *Risshō-ankoku-ron* ("Ways of Upholding Justice and Stabilizing the Nation"), addressed to the Kamakura shogunate (*see* JAPAN: *History*). It set forth the idea that good government should adhere to the ideal of righteous teaching and blamed the current social unrest on the false faith of the nation's leaders. The result was banishment to the Izu Peninsula, where he stayed for four years. Throughout his life Nichiren continued to attack the erroneous teachings of Buddhist sects (especially Jōdo, or Pure Land, Zen, Shingon, and Ritsu) and the government that supported them. He and his followers saw in the Mongol invasion (beginning in 1274) a fulfillment of his prophecies. His denunciation of the shogunate led to another four-year exile on Sado Island. Pardoned in 1274, he spent the rest of his life on Mt. Minobu with his disciples. He died on Oct. 13, 1282.

Nichiren was not the first Buddhist in Japan or China to proclaim the quintessential importance of the Lotus Sutra: this had been propounded also by the Tendai sect, in a monastery of which Nichiren had first been apprenticed. What was most original in his teaching was his emphasis: it was not understanding of but rather belief in the *sutra* that would lead the devout to enlightenment. This emphasis found expression in the form of *shōdai*, constant repetition of the name of the *sutra* (*Namu Myōhō Rengekyō*, or "Adoration to the Lotus Sutra of Perfect Truth"), and in the worship of the great Mandala (*see* MANDALA), representing the supreme truth revealed in the *sutra*.

Most conspicuous among 20th-century groups claiming to be followers of Nichiren are the Risshō Kōsei Kai and the Sōka Gakkai, the latter a politically active religious organization of growing power in the 1960s. *See* also BUDDHISM; JAPAN: *The People: Religion*.

NICHOLAS, SAINT (? 4th–5th century A.D.), the patron of schoolchildren and sailors, is the most popular of the saints who are not martyrs in both Eastern and Western churches (feast day Dec. 6). But his existence is not attested by any historical document, so nothing certain is known of his life. It is, however, highly probable that he was bishop of Myra in Lycia (Asia Minor) about the end of the 4th century, or not later than the beginning

of the 5th, for his shrine was well known at Myra from the 6th century, according to the biography of another Nicholas, the abbot of the monastery of Sion near Myra under Justinian I. The earliest account of St. Nicholas is the famous miracle of the three officers unjustly condemned to death but saved by his appearance in a dream to the emperor Constantine I; the Greek text of this *praxis de stratelatis* may go back to the 6th century and the Latin translation of it to the 8th. Legends about St. Nicholas multiplied rapidly; all the incidents of the life of Nicholas of Sion were attributed to him, as well as numerous miracles directed toward the poor, the sick and the unhappy. The best known are those of the three girls whom he dowered to save from the prostitution that poverty was forcing on them and of the three children whom he brought to life again after they had been chopped up by a butcher and put in a salting vat.

Devotion to St. Nicholas extended to all parts of the world: there were 25 churches or chapels dedicated to him in Constantinople, 45 in Rome, 40 in Iceland and so on. In 1087 Italian sailors brought his body from Myra to Bari in Apulia; this translation, commemorated on May 9, greatly increased the saint's popularity, and Bari became one of the most crowded pilgrimage centres. The name Nicholas was frequently given to persons and places in many countries; numerous surnames in European languages are derived from Nicholas (*e.g.*, in English, Nichols, Nicholson, Colson, Collins). St. Nicholas was chosen patron saint of Russia and Lorraine, as well as of various charitable fraternities and merchant guilds, particularly in France, the Netherlands, Germany and England. His miracles were a favourite subject for medieval artists and liturgical plays, and his feast day was the occasion for the ceremonies of the boy bishop (*q.v.*).

The Netherlands Protestant settlers in New Amsterdam (New York) replaced St. Nicholas ("Sinter Claes" in Dutch) by a kind of benevolent magician, Santa Claus. The transformation of St. Nicholas into Father Christmas or Father January took place first in Germany, then in countries where the Reformed churches were in the majority and finally in France, the feast day being put off to Dec. 25 or to the New Year. But there are still Catholic areas where children hang up their stockings by the chimney on the night of Dec. 5 so that St. Nicholas may fill them with toys and delicacies.

NICHOLAS, the name of five popes and one antipope.

SAINT NICHOLAS I, called THE GREAT (d. 867), pope from 858 to 867, was the most forceful of the early medieval popes. Before his election, in April 858, he had almost 15 years of service in the papal curia, and in all the acts of his pontificate he urged the supremacy of the Roman see. His reign was marked by three memorable contests, which left their mark in history. The first was that in which he supported the claims of the unjustly degraded patriarch of Constantinople, Ignatius; but two of its incidents, the excommunication of Photius (*q.v.*), the rival of Ignatius, by the pope (863) and the counterdeposition of Nicholas by Photius (867) were steps toward the permanent separation between the Eastern and the Western Churches. The second great struggle was that with Lothair of Lorraine about the divorce of his wife, Theutberga (*see* LOTHAIR). The pope not only quashed the whole proceedings against Theutberga but even created a precedent by deposing the archbishops of Cologne and of Trier, who had brought to Rome the *libellus* of the synod of Metz that declared the marriage null (863). The third great ecclesiastical affair of this pontificate was that in which the right of bishops to appeal to Rome against their metropolitans was maintained in the case of Rothad of Soissons, deposed by Hincmar (*q.v.*) of Reims. Nicholas, a strict upholder of the Roman church's primacy of jurisdiction, reinstated Rothad in 865.

Nicholas was indeed one of the master theorists of the papal plenitude of power. Deeply dependent on the writings of his great predecessors Leo the Great, Gelasius I and Gregory the Great, he was probably the first pope to draw on the False Decretals (*see* DECRETALS, FALSE). For Nicholas, the Roman church is both the head and the epitome of the universal church. It alone has all power by divine commission. As both the sacerdotal and royal functions were conferred by Christ on St. Peter, so they are exercised by St. Peter's successors, the popes. The sword of temporal power is delegated to the emperor for the protection of the church. Thus the teaching of Nicholas contained in embryonic form the complete doctrine of papal theocracy. Nicholas died on Nov. 13, 867, and his feast is celebrated on the anniversary.

NICHOLAS II (GERHARD) (d. 1061), pope from 1058 to 1061, was a Burgundian and bishop of Florence when, about Dec. 1058, he was elected at Siena to succeed Stephen X (IX) in opposition to the antipope Benedict X. He was enthroned in Jan. 1059. Nicholas II is a major figure in the reform associated with the name of Hildebrand (*see* GREGORY). In the Lateran synod of April 1059, a milestone in the Gregorian reform and in the history of the papacy, Nicholas enacted the famous decree on papal elections. In this he was expressly reacting against the disorders that had preceded his own elevation. The leading part in elections was assigned to the seven cardinal bishops, who were to deliberate together on a suitable candidate and then to call in the other cardinals. The rest of the clergy and the people were to acclaim the choice. The emperor's part in the matter was dismissed with a vague covering phrase. A legate, sent to notify the German court of this, was refused an audience, and an imperialist version of the decree was put into circulation. At a synod held in 1061 the German bishops declared the election decree void and quashed all the pope's acts. These proceedings signified the rupture of the alliance between Germany and the Holy See and heralded the contest between empire and papacy.

Nicholas had entered into friendly relations with the Normans of southern Italy in the early months of his pontificate, and this new alliance was cemented by the treaty of Melfi (Aug. 23, 1059), when he invested Robert Guiscard with the duchies of Apulia and of Calabria and the lordship of Sicily, and Richard of Aversa with the principality of Capua in return for fealty and the promise of assistance. This arrangement was destined to make the papacy more independent of both the western and eastern emperors. The immediate result was the reduction, in the following autumn, of Galeria, where the antipope Benedict X had taken refuge. Nicholas died on Aug. 27, 1061. (R. E. McN.)

NICHOLAS III (Giovanni Gaetano Orsini) (*c.* 1225–1280), pope from 1277 to 1280, was a son of the Roman senator Matteo Rosso Orsini, who had been a friend of St. Francis of Assisi and had played a great role during the pontificates of Gregory IX and Innocent IV and in the conclave which led to the election of Celestine IV. Giovanni was made cardinal deacon of St. Nicholas in Carcere Tulliano by Innocent IV as early as 1244 and thus was well versed in the business of the Roman curia when he became pope on Nov. 25, 1277. The contemporary sources stress his impressive personality, his virtue and personal integrity, but also his nepotism, because of which Dante (*Inferno* 19, 31 ff.) placed him in hell. He had been cardinal protector of the Franciscans and as pope in 1279 issued the important bull *Exiit qui seminat* which temporarily settled the struggle concerning the interpretation of perfect poverty within the order; it revoked the concessions concerning the use of money made by Innocent (*q.v.*) IV and clarified the latter's ruling that all movable and immovable possessions of the order, except those reserved by the donors, be in the ownership of the Holy See, while the friars were to have only the usufruct.

Nicholas III successfully continued Gregory X's policy of curbing the expansionist ambitions of the Sicilian king Charles I (*q.v.*) of Anjou. He did not renew Charles's positions as imperial vicar of Tuscany and senator of Rome; as far as the latter office was concerned, he legislated against its ever being filled again by a foreign ruler. At the same time he induced the German king and prospective emperor Rudolf of Habsburg to acknowledge that the Romagna with Ravenna and Bologna belonged to the papal states; though this province was not effectively incorporated until

much later, the pope thus consummated the policy of recuperations begun by Innocent III. He also succeeded temporarily in making papal arbitership and influence felt in Florence, Siena and other Tuscan cities.

It would seem that Nicholas also had adopted a constructive plan of reorganization of the Holy Roman empire. It is known for certain that the kingdom of Burgundy (Arelat) was to be given to Charles of Anjou's grandson Charles Martel (later titular king of Hungary), who was betrothed to a daughter of Rudolf of Habsburg. The kingdom of Germany, it seems, was meant to become a hereditary Habsburg monarchy, whereas imperial Italy apparently was to be divided into two kingdoms, Lombardy and Tuscany, to be ruled perhaps by papal nephews. The German king would have had no direct control of the other three kingdoms but as emperor would have remained their feudal overlord. This so-called four states project, which almost certainly would have proved beneficial, is mentioned only by Tolomeo of Lucca, but its existence is not improbable.

The early death of Nicholas III, on Aug. 22, 1280, from a stroke ruined such plans and opened the door to renewed Angevin-French influence upon the papacy under his successor, Martin IV (see MARTIN).

NICHOLAS IV (Girolamo Masci) (1227–1292), pope from 1288 to 1292, was the first Franciscan to occupy the throne of St. Peter. He was elected to succeed Honorius IV after a vacancy protracted by antagonism between the French and Italian cardinals for almost 11 months, during which six cardinals died, no doubt from malaria. He had been elected a first time on Feb. 15, 1288, but did not accept until after he had been elected a second time a week later.

Girolamo Masci was born of humble parents at Lisciano near Ascoli in the Marches. He joined the Franciscans at an early age and became the order's minister for Dalmatia. In 1272 Gregory X sent him to Constantinople, where he had a share in bringing about the short-lived union with the Greeks. From 1274 to 1279 he was minister-general of the Franciscan order; then and later during his pontificate he showed much more severity against the Franciscan Spirituals than had his predecessor as minister-general, St. Bonaventura, let alone the earlier general John of Parma. He was made cardinal priest of St. Pudenziana by Nicholas III in 1278 and in 1281 cardinal bishop of Palestrina by Martin IV.

As pope he relied very much on the Colonna, increasing the number of cardinals belonging to that family. In the bull *Coelestis altitudo* of 1289 he granted to the cardinals half of the revenues of the Roman church and a share in its administration.

Like his predecessor Martin IV, Nicholas IV, as feudal overlord of the south Italian Sicilian kingdom, tried vainly to force the royal house of Aragon to restore the island of Sicily to the south Italian Anjous. Yet he abandoned the political concept of Martin IV insofar as he terminated in 1291 the conflict between France and the kingdom of Aragon. Charles of Valois gave up his claim upon Aragon in return for the counties of Anjou and Maine which the son and successor of Charles of Anjou, Charles II (*q.v.*) of Naples, agreed to renounce in favour of his Valois cousin and namesake in the interest of concerted action against the Aragonese of Sicily.

Nicholas IV no more than any other pope after Gregory X was able to revive the idea of the crusade. During his pontificate the last remnant of the Christian crusader states, the fortress of Acre, fell to the Mameluke sultan of Egypt (1291). Even at that late date the outcome could have been different had the west availed itself of an opportunity for alliance with the Mongols against the Muslims, for which Innocent IV and St. Louis IX of France had looked in vain. This now seemed to materialize through the initiative of the Il-khan Arghun of Persia, who sent urgent requests for joint action to Nicholas IV, to Philip IV of France and to Edward I of England; but he received only promises in return. Nicholas, however, did send the Franciscan Giovanni di Monte Corvino (q.v.) to the court of Kublai Khan; this mission led to the first establishment of the Catholic Church in China, where Nestorian Christians had previously been influential. The pope also sent missionaries, mostly Franciscans, to the Balkans and the near east.

Nicholas did much for Roman architecture and art, especially in restoring the basilicas of S. Giovanni in Laterano and S. Maria Maggiore and their mosaics. He died on April 14, 1292.

(G. B. L.)

NICHOLAS V (Pietro Rainallucci) (d. 1333) was antipope in Italy from 1328 to 1330. An assembly of priests and laymen in Rome under the influence of the excommunicated emperor Louis IV of Bavaria elected this Franciscan to the papacy during the pontificate of John XXII. After John excommunicated him in April 1329, Nicholas, having obtained assurances of pardon, presented an abjuration to the pope at Avignon (Aug. 25, 1330). He remained in honourable imprisonment in the papal palace until his death on Oct. 16, 1333.

NICHOLAS V (Tommaso Parentucelli) (1397–1455), pope from 1447 to 1455, was born on Nov. 15, 1397, at Sarzana, where his father was a physician. Eugenius IV made him bishop of Bologna (1444) and a papal negotiator with the Holy Roman empire regarding the reforming decrees of the Council of Basel. He was elected to succeed Eugenius on March 6, 1447. Faced with the problem of an antipope, Felix V (*q.v.*), Nicholas, by conciliation and patience, won the abdication of Felix on April 7, 1449. The next year, in thanksgiving for the restoration of unity in the church, he held a Jubilee in Rome. He crowned Frederick III Holy Roman emperor in St. Peter's in March 1452—the last occasion in which a German emperor was crowned in Rome. In 1450 he sent Nicholas of Cusa as legate to Germany and Bohemia with the task of reforming abuses, a mission that was outstandingly successful. Nicholas was also responsible for the mission of St. John of Capistrano to Germany and that of Guillaume d'Estouteville (*q.v.*) to France.

Nicholas was perhaps the best of the Renaissance popes. He was a generous patron of humanists, eager to reconcile religion and the new learning. He employed hundreds of copyists and scholars and, by his collection of manuscripts, began the formation of the great library in the Vatican. His last years were darkened by Stefano Porcaro's conspiracy against papal government in Rome and by the fall of Constantinople, both in 1453. Nicholas died on March 24, 1455. (J. A. Ct.)

NICHOLAS I (NIKOLAI PAVLOVICH) (1796–1855), emperor of Russia from 1825, was born at Tsarskoe Selo on July 6 (new style; June 25, old style), 1796, the eighth child of the future

emperor Paul I and his consort Maria Fedorovna. He was not five years old when the murder of his father brought his eldest brother to the imperial throne as Alexander I. His education was supervised by Gen. Count M. I. von Lambsdorff, director of the 1st cadet corps and former governor of Courland, a strict disciplinarian but a miserable pedagogue who awakened little enthusiasm for learning either in Nicholas or in his elder brother Constantine (*q.v.*); and though Nicholas had various tutors, his interest remained generally limited to military matters, in spite of his mother's efforts to change this. His approach to many problems was to be that of a simple, honest and devoted officer.

In 1814, in the concluding phase of the Napoleonic Wars, the grand duke Nicholas joined the Russian headquarters in France, but not to take part in any fighting. He was with the Allies in Paris in 1815. In the following year he set out on a tour, visiting not only Moscow and the western provinces of Russia but also Prussia and England. In Berlin he was betrothed to Princess Charlotte (in Russia called Aleksandra Fedorovna), daughter of King Frederick William III of Prussia. His marriage on July 13 (N.S.; 1, O.S.), 1817, marked the beginning of a close relationship between the courts of Berlin and St. Petersburg. Nicholas gave himself over to a happy family life—his first child, the future emperor Alexander II, was born on April 29 (N.S.), 1818—and did not participate in governmental affairs. His only public role prior to his accession to the throne was as commander of a brigade of the guard and as inspector general of the engineering branch. In this capacity he showed his interest in military education and promoted the establishment of several military schools.

Accession.—Alexander I was childless, and his brother Constantine, bearing the title of tsarevich or crown prince, was expected to succeed him on the throne. But in 1823 Constantine, who lived in Poland with a Polish wife, had secretly renounced any claim to the imperial succession. When Alexander I died at Taganrog on Dec. 1 (N.S.), 1825, Nicholas, unaware of the renunciation, proclaimed Constantine emperor. Informed of the renunciation, he still hesitated to accept the crown without a public statement by Constantine, for he was too conscious of the unpopularity that his drastic discipline had earned for him in the army. A three-week interregnum ensued, and the discontented army officers took advantage of it to bring to a head a plot that had long been hatching in favour of constitutional reform. When on Dec. 26 the troops who had taken the oath to Constantine were ordered to take another to Nicholas, it was easy to persuade them that this was a treasonable plot against the true emperor. The Moscow regiment in St. Petersburg refused to take the oath, and part of it marched, shouting for "Constantine and Constitution," to the square before the senate house, where they were joined by a company of the guard and by sailors from the warships.

In this crisis Nicholas showed high personal courage. For hours he stood, or sat on horseback, amid the surging crowd, facing the mutinous soldiers while hazardous efforts were made to bring them to reason (Gen. Count M. A. Miloradovich, military governor of St. Petersburg, was mortally wounded by a pistol shot in an argument with the mutineers). When at last Nicholas consented to use force, a few rounds of grapeshot quelled the mutiny. The chief conspirators were arrested the same night and interrogated by the emperor in person. A special commission, consisting entirely of officers, was then set up; and before this, for five months, the prisoners were subjected to a rigorous inquisition. It was soon clear that the December rising was but one manifestation of a vast conspiracy permeating the whole army and embracing such aims as the abolition of serfdom and the attainment of some degree of representative government. (*See* DEKABRISTS.) Nicholas was crowned emperor in Moscow on Sept. 3 (N.S.), 1826. His coronation in Warsaw, as king of Poland, did not take place till May 24, 1829.

Internal Policy.—Nicholas saw the need for reforms and appointed a committee to examine the unfulfilled projects of Alexander I as well as other measures for the overhauling of the administration. But the revolutionary movement in western Europe, breaking out in 1830, prompted the shelving of most of the committee's proposals, as Nicholas turned increasingly to military discipline as the means of rejuvenating the tired and corrupt administration. He put civil servants, professors and students into uniform and, for little offenses, had them marched to the guardhouse. Though a certain autonomy was extended to the universities—they elected their own deans and professors—the expression of thought was censored. The army was disciplined by an unceasing round of parades and inspections which left it woefully unprepared for actual combat. In general, everything was done to protect Russia from foreign revolutionary influence. Students were no longer sent to study in western Europe, and travel abroad was restricted. Meanwhile a secret police network, the dreaded "third section" of the emperor's private chancery, had been established in July 1826; and a policy of russification was pursued throughout the empire to make the idea of nationality (*narodnost*), together with Orthodox Christianity and autocracy, one of the pillars of Russian absolutism. Nicholas was not blind to the evils of Russian society (he regarded serfdom as an evil), but he feared that changes would be worse yet.

The reign saw much emphasis on bureaucracy and officialdom, yet Nicholas was reluctant to delegate authority. In this he resembled his contemporary, the emperor Francis I of Austria. But whereas Francis would "sleep upon" a difficult problem, Nicholas never did. His constitution was of iron, his capacity for work prodigious: reviews and parades, receptions of deputations, visits to public institutions, then eight or nine hours in his cabinet to deal with reports and dispatches—such was his ordinary day's work. Under the "Iron Tsar" the outward semblance of authority was perfectly maintained; but behind this façade the whole structure of the administrative system continued to rot.

Foreign Affairs.—Throughout his reign Nicholas I sought to discipline Russia and, by means of a disciplined Russia, to discipline the world. Russia's mission in the west was, in accordance with the principles of the Holy alliance (*q.v.*) as Nicholas interpreted them, to uphold the cause of legitimacy and autocracy against revolution; and in the east it was, with or without the co-operation of "Europe," to advance the cause of Orthodox Christianity, of which Russia was the natural protector, at the expense of the decaying Ottoman Turkish empire (*see* EASTERN QUESTION). The sympathy of Europe with the insurgent Greeks gave Nicholas an early opportunity (*see* GREEK INDEPENDENCE, WAR OF). Great Britain sent the duke of Wellington to St. Petersburg in 1826 not only to congratulate the new emperor on his accession but also to concert a policy on the Eastern question. The upshot proved the diplomatic value of Nicholas' apparent sincerity of purpose and charm of manner: the "Iron Duke" was to the "Iron Tsar" as soft iron to steel; and the British found themselves committed, without efficient guarantees for the future, to a policy that turned out very much to Russia's advantage. The execution of this policy, however, incidentally exposed the rottenness of Russia's administrative system.

The newly organized Russian naval squadron on its way to join the British and the French in the Ionian sea reached the English channel only with difficulty and had to be completely refitted at Plymouth before it could proceed; yet it arrived in time to participate in the destruction of Ottoman seapower in the unforeseen battle of Navarino (Oct. 20, 1827). When overt war broke out between Russia and Turkey in 1828 (*see* RUSSO-TURKISH WARS) the emperor went to join his troops on their march through the Balkans toward Istanbul, hampering by his presence the initiative of the nominal commander in chief (Prince L. A. P. von Wittgenstein) and obliging the soldiers, weary and starving in the marshes of Dobruja, to parade before him as smartly as if they were at St. Petersburg. When hundreds died of scurvy or dysentery, Nicholas could do nothing to repair the scandalous inefficiency of the commissariat or of the hospital service. Even so, the peace treaty of Adrianople (Edirne; Sept. 14, 1829) seemed to reduce Turkey to a position little better than that of vassalage to Russia; and the Russo-Turkish treaty of Unkiar Skelessi (July 8, 1833) after the first revolt of Mohammed Ali of Egypt against Turkey strengthened Russia's hand still further.

In the west Nicholas himself proposed an armed intervention of the Holy alliance "to restore order" after the July revolution in France and the Belgian revolution (1830). When Austria and

Prussia held back, he even proposed to intervene alone; but this project was rendered impracticable by the outbreak of the great insurrection in Poland (Nov. 29, 1830), which tied the hands of all three powers.

After the Poles had been crushed (1831), Nicholas went in person to reach an understanding with Austria on the Eastern question at Münchengrätz (Mnichovo Hradiste) in Sept. 1833. This enabled his minister K. R. von Nesselrode to draw Austria and Prussia into a reproduction of the Holy alliance with Russia by the secret convention of Berlin (Oct. 15, 1833), whereby they reaffirmed the right and duty of intervention at the request of a legitimate sovereign. When the emperor Ferdinand I had succeeded his father Francis I on the Austrian throne (1835), Nicholas went to renew the Austro-Russian understanding in Sept.–Oct. 1835 through meetings at Teplitz (Teplice) and in Prague. At these meetings he recommended the eventual suppression of the republic of Cracow by Austria, since Cracow was a centre of revolutionary agitation (though Austrian, Russian and Prussian troops occupied the territory from 1836 to 1841, formal annexation was deferred till 1846); and he was also persuaded by Metternich, the Austrian chancellor and minister of foreign affairs, to support the cause of Don Carlos in Spain. As early as May 1837, in view of the agitation in Hungary, he announced that "in every case" Austria might count on Russia.

These cordial ties were loosened when war broke out in Syria between Turkey and Egypt in 1839. Metternich was anxious to summon a European conference to Vienna, with a view to placing Turkey under a collective guarantee, but Nicholas refused to be a party to it. Moreover, as Austria showed an inclination to consult both Great Britain and France, Nicholas decided to come to an agreement with Great Britain in order to settle the Eastern question according to his own views and without reference to the France of the July monarchy. He therefore departed so far from the position given to him by the treaty of Unkiar Skelessi and made such concessions that the convention of London (July 15, 1840) could be concluded between Russia, Great Britain, Austria and Prussia for the settlement of the question regardless of France's views. The new Anglo-Russian entente led in June 1844 to a visit of the emperor to England.

The imperial regime in Russia was unshaken by the European revolutionary movement of 1848; and in 1849 Nicholas sent his army into Hungary, at the request of the young Austrian emperor Francis Joseph, to crush the insurgent Hungarians. He also did a valuable service to Austria during the German crisis of 1850. Prussia was then trying to organize a new union of German states that would have put an end to the predominance enjoyed by Austria in the German confederation as set up in 1815; and the troubles that broke out in Electoral Hesse might have led to war between Austria and Prussia if both powers had persisted in intervening at cross purposes there (*see* GERMANY: *History*). At a meeting in Warsaw, however, in Oct. 1850, Nicholas told the Prussian prime minister, Friedrich Wilhelm, graf von Brandenburg, that in order not to forfeit Russia's friendship Prussia must adhere to the settlement of 1815 and to the entente with Austria. Thus deterred by Nicholas, Prussia submitted to Austria's will in the punctation of Olmütz (Olomouc) in November.

Nicholas was soon to be disappointed in his faith in Austria's friendship. In 1853, when the dispute arose with the French emperor Napoleon III over the guardianship of the Holy Places in Palestine (*see* CRIMEAN WAR), Nicholas could not believe that Christian powers would resent his claim to protect the Christian subjects of Turkey. On the contrary, he thought that Austria was in gratitude bound to be at least neutral, if not favourable to him; that Prussia would adopt a similar position; and that he could hope to come to a frank understanding with Great Britain. Having in June 1853 ordered his armies to occupy Turkish Moldavia and Walachia, he conferred with Francis Joseph at Olmütz in September and met him again, with the Prussian king Frederick William IV, in Warsaw in October. Finally, however, when France and Great Britain had already declared war on Russia, both Austria and Prussia subscribed to an agreement with the allies guaranteeing the integrity of the Turkish empire (April 9, 1853) and then proceeded to sign a defensive alliance of their own (April 20, 1854) which would come into operation if the Russians annexed the banks of the Danube or marched on Istanbul. Thus Nicholas, the professed champion of the European alliance, found himself obliged to withdraw his troops from the Balkans at Austria's behest in the summer of 1854. The Franco-British invasion of the Crimea followed, and with it a fresh exposure of the corruption of the Russian system. At the outset Nicholas had grimly remarked that "Generals January and February" would prove his best allies, but they acted impartially: if thousands of British and French soldiers perished of cold and disease in the trenches before Sevastopol, the tracks leading from the centre of Russia into the Crimea were marked by the bones of Russian dead. Disillusion broke the emperor's spirit; he neglected ordinary precautions for his health; and, on March 2 (N.S.; Feb. 18, O.S.), 1855, he died of pleurisy.

NICHOLAS II (NIKOLAI ALEKSANDROVICH) (1868–1918), the last Russian emperor, was born at Tsarskoe Selo on May 18 (new style; 6, old style), 1868, the eldest son of the tsarevich Aleksandr Aleksandrovich (emperor as Alexander III from 1881) and his consort Maria Fedorovna (Dagmar of Denmark). Succeeding his father on Nov. 1 (N.S.), 1894, he was crowned in Moscow on May 26 (N.S.), 1895.

Character and Views.—Neither by upbringing nor by temperament was Nicholas fitted for the complex tasks that awaited him as autocratic ruler of a vast empire. He had received a military education from his tutor, Gen. G. G. Danilovich, and his tastes and interests were those of the average young Russian guards officer of his day. He had few intellectual pretensions, but delighted in physical exercise and the minutiae of army life: uniforms, insignia, parades. Yet on formal occasions he felt ill at ease. Though he possessed great personal charm he was by nature timid; he shunned close contact with his subjects, preferring the privacy of his family circle. His domestic life was serene. To his wife Alexandra (*q.v.*), whom he had married on Nov. 26 (N.S.), 1894, Nicholas was passionately devoted. She had the strength of character that he lacked, and he fell completely under her sway. She communicated to him her morbid mystical outlook. Under her influence he sought the advice of spiritualists and faith healers, most notably G. E. Rasputin (*q.v.*), who eventually acquired great power over the imperial couple. Nicholas also had other irresponsible favourites, often men of dubious probity who provided him with a distorted picture of Russian life, but one that he found more comforting than that contained in official reports. He distrusted his ministers, mainly because he felt them to be intellectually superior to himself and feared that they sought to usurp his sovereign prerogatives. His view of his role as autocrat was childishly simple: he derived his authority from God, to whom alone he was responsible, and it was his sacred duty to preserve his absolute power intact. However, he lacked the strength of will necessary in one who had such an exalted conception of his task. In pursuing the path of duty Nicholas had to wage a continual struggle against himself, suppressing his natural indecisiveness and assuming a mask of self-confident resolution. His dedication to the dogma of autocracy was an inadequate substitute for the constructive policy which alone could have prolonged the imperial regime.

Soon after his accession Nicholas proclaimed his uncompromising views in an address to liberal deputies from the *zemstva* in which he dismissed as "senseless dreams" their aspirations to share in the work of government. To the rising groundswell of popular unrest he replied with intensified police repression. In foreign policy, his naïveté and lighthearted attitude toward international obligations sometimes embarrassed his professional diplomats; *e.g.*, when he concluded an alliance with the German emperor William II during their meeting at Björkö in July 1905. He was the first Russian sovereign to evince personal interest in Asia. In 1891, while still tsarevich, he visited India, China and Japan; and later he nominally supervised the construction of the Trans-Siberian

railway. The forward policy he pursued in regard to Korea, where he had private financial interests, was partly responsible for the Russo-Japanese War (1904–05). The outcome of this struggle not only frustrated Nicholas' grandiose dreams of making Russia a great Eurasian power with China, Tibet and Persia within its sphere of influence but also faced him with serious problems at home, where discontent grew up into the revolutionary movement of 1905.

Domestic Affairs.—Nicholas considered all who opposed him, regardless of their views, as malicious conspirators. Disregarding the advice of S. Y. Witte, his prime minister, he refused to make concessions until events forced him to yield more than might have been necessary had he been more flexible. On March 3 (N.S.), 1905, he reluctantly agreed to the creation of a national representative assembly or duma (*q.v.*) with consultative powers; and by the manifesto of Oct. 30 he promised what was virtually a constitutional regime: no law was to take effect without the duma's consent. Nicholas, however, cared little for an undertaking extracted from him under duress. He strove to regain his former powers and ensured that in the new "fundamental laws" (May 1906) he was still designated an autocrat. He furthermore patronized an extremist right-wing organization, the Union of Russian Men, which sanctioned terrorist methods and disseminated anti-Semitic propaganda. Witte, whom Nicholas blamed for the October manifesto, was soon dismissed, and the first two dumas were prematurely dissolved as "insubordinate." P. A. Stolypin, who carried out the coup of June 16, 1907, whereby the second duma was dissolved, was loyal to the dynasty and a capable statesman. But the emperor distrusted him and allowed his position to be undermined by intrigue. Stolypin was one of those who dared to make representations about Rasputin's influence and thereby incurred the displeasure of the empress. In such cases Nicholas generally hesitated but ultimately yielded to Alexandra's pressure. To prevent exposure of the scandal he interfered arbitrarily in matters properly within the competence of the Holy synod.

Foreign Affairs.—In foreign affairs attention now centred on the Balkans. Nicholas sympathized with the national aspirations of the Slavs and was anxious to win control of the Turkish straits, but tempered his expansionist inclinations with a sincere desire to preserve peace among the great powers. After the assassination of the Austrian archduke Francis Ferdinand at Sarajevo he tried hard to avert the impending catastrophe by diplomatic action and resisted, until July 30 (N.S.), 1914, the pressure of the military for general, as distinct from partial, mobilization. The outbreak of World War I temporarily strengthened the monarchy, but Nicholas did little to maintain his people's confidence. The duma was slighted, and voluntary patriotic organizations were hampered in their efforts; the gulf between the ruling group and public opinion grew steadily wider. Alexandra turned Nicholas' mind against the popular commander in chief, his father's cousin the grand duke Nicholas (Nikolai Nikolaevich); and on Sept. 5, 1915, he dismissed him, assuming supreme command himself. Almost all his ministers protested against this step as likely to impair the army's morale, since the emperor had no experience of war. They were overruled and soon found themselves dismissed.

Nicholas II did not in fact interfere unduly in operational decisions, but his departure for headquarters had serious political consequences. In his absence supreme power in effect passed, with his approval and encouragement, to the empress. A grotesque situation resulted: in the midst of a desperate struggle for national survival competent ministers and officials were dismissed and replaced by worthless nominees of Rasputin. The court was widely suspected of treachery, and antidynastic feeling grew apace. Conservatives plotted Nicholas' deposition in the hope of saving the monarchy. Even the murder of Rasputin failed to dispel Nicholas' illusions: he blindly disregarded this ominous warning, as he did those by other highly placed personages, including members of his own family. His isolation was virtually complete.

Abdication and Death.—When riots broke out in Petrograd on March 8 (N.S.), 1917, Nicholas instructed the city commandant to take firm measures and sent troops to help restore order. It was too late. The government resigned, and the duma, supported by the army, called on the emperor to abdicate. At Pskov, on March 15, with fatalistic composure, Nicholas renounced the throne—not, as he had originally intended, in favour of his son Alexis, but in favour of his brother Michael. Michael, however, refused the crown.

Nicholas was detained at Tsarskoe Selo. It was planned to send him and his family to England; but instead, mainly because of the opposition of the Petrograd soviet, they were removed to Tobolsk, in western Siberia. This step sealed their doom. In Apr. 1918 they were taken to Ekaterinburg (now Sverdlovsk) in the Urals. When "White" Russian forces approached the area the local authorities were ordered to prevent a rescue; and in the night of July 29–30 (N.S.; 16–17 O.S.) the prisoners were all slaughtered in the cellar of the house where they had been confined. The bodies were burned and cast into an abandoned mineshaft, but the facts were established by investigation after Ekaterinburg had been taken by the "White" forces. The *Journal intime de Nicolas II* was published in 1925 and *The Letters of the Tsar to Tsaritsa, 1914–1917* in 1929. For portrait *see* article RUSSIAN HISTORY.

NICHOLAS I (1841–1921), prince of Montenegro from 1860 and king from 1910 to 1918, was born at Njegosh on Oct. 7 (new style; Sept. 25, old style), 1841, the son of Mirko Petrovich-Njegosh. Heir presumptive to his uncle Danilo II, he was educated at Trieste and at the *lycée* Louis-le-Grand in Paris. Returning to Montenegro as prince after Danilo's assassination (Aug 13, 1860), he took part in the campaign of 1862 against the Turks, which after Austrian intervention was followed by a long period of peace. On a visit to St. Petersburg in 1868 he was well received by the Russian emperor Alexander II, who thereafter supplied him regularly with arms and money and on one occasion referred to him as his "only friend." During the international crisis that arose from the revolt of Hercegovina against Turkish rule, Nicholas declared war on Turkey in July 1876 and won brilliant successes in the ensuing campaigns (*see* EASTERN QUESTION). He took Bar and Ulcinj; and the congress of Berlin (1878) recognized Montenegro as a sovereign state, with its previous area doubled and access to the Adriatic at Bar. Nicholas, who in 1860 had married Milena (1847–1923), daughter of Petar Vukotich, now proceeded to seek useful dynastic connections. Of his daughters, Zorka was married in 1883 to Peter Karageorgevich (she died, however, in 1890, before Peter became king of Serbia); two were married to Russian grand dukes; and Elena was married in 1896 to the future Victor Emmanuel III of Italy. He himself assumed the style of "Royal Highness" in Dec. 1900. Meanwhile he had begun to intrigue, sometimes with and sometimes against Peter Karageorgevich, for the formation of a Yugoslav state to comprise both Montenegro and Serbia.

Discontent at his despotic rule in Montenegro forced Nicholas to grant a constitution in 1905. Quarrels with political opponents culminated in the "Cetinje bomb plot" against him (1907), which led to severance of relations with Serbia till 1908.

On Aug. 28, 1910, Nicholas proclaimed himself king of Montenegro. The Balkan War of 1912–13 began with his declaration of war against Turkey (*see* BALKAN WARS), but the resultant acquisition of territory by Montenegro was less than had been hoped, so that the dynasty lost prestige. Nicholas at first made common cause with Serbia in World War I, but asked Austria-Hungary for a separate peace on Jan. 13, 1916, before taking refuge in Italy. When the Serbians had occupied Montenegro, a "national assembly" proclaimed his deposition and that of his dynasty (Nov. 1918); and on March 2, 1921, Nicholas died in exile, at Antibes in France. The small monarchist party of Montenegro then proclaimed his eldest son Danilo (1871–1939), as king, but Danilo on March 7 abdicated his rights in favour of his nephew Michael (1908–).

Nicholas I was a talented writer of plays, poems and songs.

(R. G. D. L.)

NICHOLAS (NIKOLAI NIKOLAEVICH) (1856–1929), Russian grand duke and army officer, commander in chief against the Ger-

mans and Austro-Hungarians in the first year of World War I. He was born in St. Petersburg on Nov. 18 (new style; 6, old style), 1856, the son of the emperor Alexander II's brother, the grand duke Nikolai Nikolaevich "the Elder." Educated at the general staff college, he received his commission in 1872. In the Russo-Turkish War of 1877–78 he served on the staff of his father, then commander in chief of the Russian forces. He next joined the Guard Hussar regiment, becoming its commander in 1884. He was appointed inspector general of cavalry in 1895 and held this post for ten years, during which he introduced fundamental reforms in training and equipment. When he was appointed in 1905 to be commander of the St. Petersburg military district he again demonstrated his enthusiasm for the effective training of his troops, especially in the application of modern methods and of the lessons learned from the Russo-Japanese War.

In 1905 Nicholas was also appointed first president of the newly created imperial committee of national defense, a position that he held until its abolition in 1908, when Gen. V. A. Sukhomlinov became chief of the general staff. Sukhomlinov also became minister of war in 1909 and was entrusted by the emperor Nicholas II with the strategic planning for the war expected to break out in Europe: the grand duke Nicholas had no part in this planning. On the outbreak of war against Germany and Austria-Hungary in 1914, however, the emperor, though he had intended to take over the active command of the armies himself, yielded to the advice of his ministers and to popular opinion and appointed the grand duke Nicholas to be commander in chief. During the war the grand duke adapted the plans already made by the general staff and proved himself an extremely able commander. On Sept. 5 (N.S.; Aug. 23, O.S.), 1915, however, the emperor assumed the supreme command and sent the grand duke to the Caucasus as viceroy and commander in chief. This appointment gave new heart to the Russian forces ranged against Turkey, and they took the offensive with some success.

The grand duke was still in the Caucasus at the time of the Russian revolution of March 1917. The emperor's last official act was to appoint him once more commander in chief; but within 24 hours of the grand duke's arrival at his new headquarters in Mogilev his appointment was canceled by Prince G. E. Lvov, head of the provisional government. For two years Nicholas remained in the Crimea, but in March 1919 he left Russia in a British cruiser. He lived quietly in France until his death at Antibes on Jan. 6, 1929.

See V. A. Sukhomlinov, *Veliki knyaz Nikolai Nikolaevich* (1925); Yu. N. Danilov, *Le Premier Généralissime des armées russes, le grand duc Nicolas* (1932); Bernard Pares, *The Fall of the Russian Monarchy* (1939). (I. Gy.)

NICHOLAS OF CUSA (NIKOLAUS VON CUSA, NICOLAUS CUSANUS) (1401–1464), scholar and churchman, was the son of a Moselle boatman named Krypffs or Krebs. He studied the arts, philosophy, law, mathematics, the sciences and theology at Deventer, Heidelberg, Padua, Rome and Cologne (1413–25) and was ordained priest *c.* 1430. To his colleagues at the council of Basel he dedicated his book *De concordantia catholica* (*On Catholic Concordance;* 1433), in which he stressed the harmony of the church as the supreme society on earth. The pattern for priestly concord he found in the heavenly orders. He maintained the supremacy of general councils over divinely commissioned but strictly limited papal power. Later, however, he became a critic of conciliar politics and an ally of the papacy (1437). He negotiated with the Hussites and served on a commission to Constantinople, seeking the reunion of Eastern and Western Christendom (1437). Philosophy and mathematics were conjoined in his work *De docta ignorantia* (*Of Learned Ignorance;* 1440), in which he described the learned man as one aware of his own ignorance. Such wise unknowing led to a faith transcending reason. The way was thus opened for the mystical life described in his *De visione Dei* (*Vision of God;* 1453).

Nicholas became a cardinal in 1448 and bishop of Brixen, in the Tirol, in 1450. He was papal legate for reform in Germany and the Netherlands (1450–52). Attempted reform of his own diocese (1453–58) ended with his eviction by secular powers (1459). He died at Todi in 1464.

Nicholas emphasized mathematics and experimental knowledge, including diagnostic medicine and applied science. Before Copernicus he discerned a universal movement involving but not centred in the earth; he denied that celestial bodies are strictly circular in form and motion. (*See* also SCIENCE, HISTORY OF: *The Renaissance and Early Modern Science.*) He conceived God as irreducible unity, the coincidence of all contradictions, that which enfolds all things in its infinite simplicity, even as it unfolds all. Cusa flatly disavowed pantheism. All things are in God as things caused are in the cause; this, he held, in no way identified creatures with their creator.

Christ was envisaged as the perfect mediator between God and man, the union between the divine nature that created and the human nature that was created. Humanity experienced its true nobility and personalized freedom in cosmic community with Christ. He was celebrated as the incarnate Word of the sermon and the heart of the saving eucharistic mystery. In Christ's mystical body and sacramental unity, Cusa found the cure of Bohemian separatism, the hope for Greek-Latin reunion and the reconciliation in worshiping diversity that would ultimately unify all faiths. Cusa reflected sources as divergent as the Neoplatonists, Eckhart, the Christian Fathers and the Averroists. His role in the history of thought deserves perennial re-evaluation.

Nicholas' *Opera Omnia* were edited by E. Hoffmann and P. Wilpert (1932 *et seq.*); and also may be found in *Schriften in deutscher Übersetzung* (1936 *et seq.*). English translations are E. Gurney-Salter, *The Vision of God* (1928), and G. Heron, *Of Learned Ignorance* (1954).

Jacob, *Essays in the Conciliar Epoch* (1953); M. de Gandillac, *Nikolaus von Cues* (1953); E. Cassirer, *Individuum und Kosmos in der Philosophie der Renaissance* (1927); G. Heinz-Mohr, *Unitas Christiana* (1958). (RA. C. P.)

NICHOLAS OF DAMASCUS (NICOLAUS DAMASCENUS) (fl. 1st century B.C.), Greek historian and philosopher of Damascus, whose works included a universal history from the time of the Assyrian empire to his own days. He instructed Herod the Great in rhetoric and philosophy, and attracted the notice of Augustus when he accompanied his patron on a visit to Rome. Later, when Herod's conduct aroused the suspicions of Augustus, Nicholas was sent on a mission to bring about a reconciliation. He survived Herod and it was through his influence that the succession was secured for Herod Archelaus; but the date of his death, like that of his birth, is unknown. Fragments of his universal history, his autobiography and his life of Augustus have been preserved, chiefly in the extracts of Constantine Porphyrogenitus. *See* CONSTANTINE: *Constantine VII.*

For fragments *see* L. Dindorf (ed.), *Historici Graeci minores,* vol. i (1870). The text of his life of Augustus, with Eng. trans. and commentary, was edited by C. M. Hall (1923). F. Navet, *Nikolaus von Damaskus* (1853), contains an account of his life and translation of the fragments.

NICHOLAS OF LYRA (NICOLAUS LYRANUS) (*c.* 1265–1349), called by Martin Grabmann "the foremost exegete of the Franciscan-Scotistic school," was born at Lire (now Vieille-Lyre) in Normandy. He entered the Franciscan order at Verneuil about 1300, studied at Paris, became a professor before 1309 and taught for many years in the Sorbonne. From 1319 he was provincial of his order in France and in 1325, as provincial of Burgundy, he founded the College of Burgundy at Paris, where he died in the autumn of 1349.

Nicholas' most important writing is the monumental 50-volume *Postillae perpetuae in universam S. Scripturam,* a commentary on the whole Bible, first according to the literal sense, then according to a mystical or spiritual exposition. This book, the first commentary printed, soon became a favourite manual of exegesis, and some scholars claim that it exerted an important influence on Luther. The prime significance of the work is the author's insistence, against the allegorical interpretations common in his time, on the literal sense as the foundation for all mystical applications. Nicholas also wrote on the Eucharist, the Beatific Vision and other matters, including a book of devotions. (WM. J. B.)

NICHOLAS, SIR EDWARD (1593–1669), English statesman and secretary of state under Charles I, was born at Winter-

bourne Earls, Wiltshire, on April 4, 1593. He was educated at Salisbury grammar school, Winchester and Queen's college, Oxford. After studying law at the Middle Temple, Nicholas became in 1618 secretary to Lord Zouche, warden and admiral of the Cinque ports, and continued in a similar employment under the duke of Buckingham. He was member of parliament for Winchelsea in 1621 and 1624 and for Dover in 1628. He became secretary to the admiralty, then extra clerk of the privy council with duties relating to admiralty business in 1626; and he was one of the clerks in ordinary to the council (1635–41). In this situation Nicholas was concerned with the levy of ship money. He had Charles's confidence, became a privy councilor and a secretary of state in Nov. 1641, attended the king at Oxford and was one of the royal commissioners at the treaty of Uxbridge (Feb. 1645). Nicholas helped to arrange the details of the king's surrender to the Scots, though he does not appear to have approved of the step, and he signed the capitulation of Oxford. He went to France, and after the king's death remained on the continent.

Despite his friendship with Sir Edward Hyde, he had little influence with Charles II and two years after the Restoration he was persuaded to resign his secretaryship. He died at West Horsley, Surrey, on Sept. 1, 1669.

Much of Nicholas' correspondence is printed in *The Nicholas Papers*, 4 vol. (1886–97), and in *The Diary and Correspondence of John Evelyn*, ed. by W. Bray (1906). *See* also D. Nicholas, *Mr. Secretary Nicholas* (1955). (R. B. Wm.)

NICHOLS, JOHN (1745–1826), English writer, printer and antiquary, who in the *Gentleman's Magazine*, with which he was connected from 1778 until his death, and in numerous volumes of literary anecdotes, made an invaluable contribution to knowledge of the lives and works of 18th-century men of letters. Born at Islington, Feb. 2, 1745, he was apprenticed in 1757 to William Bowyer the younger, "the learned printer," who took him into partnership in 1766. His first literary work was as editor of Swift (1775–1779) but his career as biographer to his age was begun by his memoir of Bowyer, expanded into *Anecdotes of William Bowyer and His Literary Friends* (1782), which formed the basis of *The Literary Anecdotes of the 18th Century* (1812–15). The supplementary *Illustrations of the Literary History of the 18th Century*, begun in 1817, was completed by his son, John Bowyer Nichols (1779–1863).

Nichols became part manager of the *Gentleman's Magazine* in 1778 and sole manager and editor in 1792. His antiquarian studies, based on his own accurate observation and research, included a *Bibliotheca Topographica Britannica* (1780–90) and the *History and Antiquities of Leicester* (1795–1815), perhaps his most important original work. Of many friendships and literary collaborations—with Joseph Warton, Richard Gough, Bishop Percy—that with Samuel Johnson was one of the most valuable, and as publisher of the *Lives of the English Poets* he exercised considerable editorial influence and supplied its author with much information. All his work showed the care which caused Walpole to say of his *Life of Mr. Bowyer*, "I scarce ever saw a book so correct."

Nichols died in London, Nov. 26, 1826.

See articles by E. Hart, *PMLA* (Publications of the Modern Language Association of America), vol. lxv (1950), vol. lxvii (1952).

NICHOLSON, JOHN (1822–1857), Irish soldier and administrator who rendered outstanding service during the Indian mutiny, was born in Lisburn on Dec. 11, 1822, and educated at Dungannon college. His uncle Sir James Hogg secured him a Bengal army cadetship in 1839 and during the first Afghan War he distinguished himself in the defense of Ghazni (1841–42) before enduring several months' souring captivity in Afghan hands. In Afghanistan he met Henry (later Sir Henry) Lawrence who, after the First Sikh War secured him a political post first in Kashmir and then in the Punjab. In 1848, during the Second Sikh War, Nicholson seized the important Attock crossing and delayed Sikh concentration. During Lord Gough's campaigns he secured intelligence, marshaled supplies and headed the drive to the Afghan borders.

After the Punjab was annexed he took charge of Bannu, reducing that wild district to quiet and creating a legend by his personal activity, fearlessness, and prompt, if severe, justice. He embodied the Punjab myth of justice administered in shirt sleeves, of ubiquitous activity, of the strong paternal administrator, though his disregard for regulations and office work called down the reproofs of both Henry and John Lawrence.

With the outbreak of the Indian mutiny in 1857 his vigour, decision and delight in action found full employment. He supported Herbert Edwardes at Peshawar in disarming the sepoy regiments there, led the pursuit and destruction of the 55th regiment when they fled from Nowshera and helped dissuade John Lawrence from abandoning Peshawar. In June, promoted to the rank of brigadier general, he led a movable column (*i.e.*, troops equipped for quick movement) toward Delhi. On the way he disarmed or destroyed other mutinous regiments and defeated a force of mutineers near Gurdaspur. His arrival at Delhi early in August and his brilliant victory at Najafgarh inspirited the British forces while he nerved Brig. Gen. Archdale Wilson to risk an assault. On Sept. 14 he led the attacking column against the Kashmir gate. He took his objective, but while working westward along the defenses to link with the fourth column was shot leading a frontal assault upon enemy guns. He died in Delhi on Sept. 23.

See L. J. Trotter, *The Life of John Nicholson*, 9th ed. (1904); Hesketh Pearson, *The Hero of Delhi* (1948). (J. B. Ha.)

NICHOLSON, REYNOLD ALLEYNE (1868–1945) English orientalist, lecturer in Persian (1902–26) and Sir Thomas Adams professor of Arabic (1926–33) at Cambridge university was a foremost scholar in the fields of Islamic literature and mysticism. He was born at Keighley, Yorkshire, on Aug. 18, 1868. His *Literary History of the Arabs* (1907) remains the standard work on that subject in English; while his many text editions and translations of Sufi writings, culminating in his eight-volume *Mathnawi of Jalalu'ddin Rumi* (1925–40), advanced the study of Muslim mystics to an eminent degree. He combined exact scholarship with notable literary gifts; some of his versions of Arabic and Persian poetry entitle him to be considered a poet in his own right. His deep understanding of Islam and of the Muslim peoples was the more remarkable in that he never traveled outside Europe. A shy and retiring man, he proved himself an inspiring teacher and an original thinker; he exercised a lasting influence on Islamic studies. He died at Chester on Aug. 27, 1945.

See "Reynold Alleyne Nicholson," *Proceedings of the British Academy*, vol. xxxi (1945); A. J. Arberry, introduction to *Pages From the Kitāb al-Luma'* (1947). (A. J. Ar.)

NICHOLSON, SIR WILLIAM NEWZAM PRIOR (1872–1949), English painter, engraver, theatre designer and illustrator, was born at Newark-on-Trent on Feb. 5, 1872. At Herkomer's school, London, he met James Pryde, with whom he collaborated under the pseudonym "J. and W. Beggarstaff" to produce strikingly bold posters (1893–98). He studied at the Académie Julian, Paris, 1889–90. His illustrations to *An Alphabet* *An Almanack of Twelve Sports* and *London Types* in 1898 and the woodcut "Portrait of Queen Victoria" earned him wider recognition. He made sets for *Peter Pan* in 1904. Nicholson's paintings, whether landscapes, portraits or still life, are characterized by solid construction and heavy colour, as in "Girl With the Tattered Glove" (1909, Fitzwilliam museum, Cambridge) "Mushrooms" (1940, Tate gallery, London) and "The Stack Hoar's Fields" (1925). He was knighted in 1936, and died on May 16, 1949, at Blewbury, Berkshire.

His eldest son, Ben Nicholson (1894–), leading English abstract painter, was born on April 10, 1894, at Denham, Buckinghamshire. After studying briefly at the Slade School of Art he traveled extensively in Europe during 1911–18 and held his first one-man show in London in 1922. From 1920, under the influence of Cubism and the De Stijl movement, he began his severe, geometrical designs, notable for an icy brilliance of colour, which culminated in the series of constructions "White Reliefs" of 1935–39 (one of 1935 in the Tate gallery). He was a member of Abstraction-Création, Paris (1933–35), and coedited *Circle* (1937).

See Lillian Browse, *William Nicholson*, with bibliography (1956); Sir Herbert Read, *Ben Nicholson*, 2 vol. (1948, 1956). (D. L. Fr.)

NICIAS (d. 413 B.C.), Athenian general and statesman, noted for his wealth and piety. In 427 he captured the small island of

Minoa, blocking the Megarian harbour of Nisaea, and next year he sailed to Melos and Oropus. In 425, when the Athenian force at Pylos failed to capture the Spartans on Sphacteria and Cleon complained of the generals' slackness, he resigned this command to Cleon, who spectacularly fulfilled his promise to bring the Spartans alive within 20 days, or destroy them. Nicias recovered his reputation in an expedition against Corinth later in the year, and by taking the Spartan island of Cythera in 424. He had no part in the Athenian defeat at Delium that year, and now concentrated on making peace, though he helped to recover Mende in the north during the truce of 423.

The deaths of Cleon and Brasidas in 422 made it easier to negotiate the "Peace of Nicias" (spring 421) and an alliance with Sparta, but the hostility of Sparta's allies and the opposition of Alcibiades (*q.v.*) foiled Nicias' efforts to uphold the peace. In 417 an ostracism (*q.v.*) was held, in the hope of exiling Nicias or Alcibiades, but instead they joined to procure the ostracism of the demagogue Hyperbolus.

In 415 he was appointed, most unwillingly, as one leader of the expedition to Sicily. The recall of Alcibiades and the death of Lamachus left him, while ill with kidney trouble, in sole charge of the siege of Syracuse. The circumvallation was not completed and the Spartan Gylippus succeeded in building a counter-wall. Nicias asked to be relieved of his command, but instead reinforcements came early in 413 with Demosthenes. When these failed to reverse the situation, Demosthenes favoured departure, but an eclipse of the moon and Nicias' superstition delayed it till too late. The disastrous retreat by land ended in the surrender of the force. The Syracusans executed Nicias.

See, for bibliography, PELOPONNESIAN WAR. (A. As.)

NICKEL (symbol Ni), a grayish-white metallic element, hard, tough and markedly resistant to oxidation and corrosion. It is widely familiar because of its use in coinage, but has become more important for its many domestic, industrial and military applications. The metal itself is well suited for direct use in many kinds of mechanical equipment, but it is more commonly employed in the form of alloys. Use in this form dates from prehistoric times, for early man fashioned some of his implements from meteoric iron, which normally contains 5% to 15% nickel. It was also used in alloy form by the Chinese in ancient days, but nickel itself was not isolated until 1751, when A. F. Cronstedt prepared an impure sample from an ore containing niccolite (NiAs). An ore of this same type had earlier caused copper and silver miners in Saxony considerable trouble because although it resembled copper in colour it yielded a brittle unfamiliar product. They came to refer to it as "kupfernickel," after "Old Nick" and his mischievous gnomes, and Cronstedt applied their name to his new element. His results were confirmed in 1775 by T. O. Bergman, and the name nickel soon became generally accepted. About a century elapsed before nickel was mined in quantity for a growing world market.

Occurrence and Production.—Nickel is the 24th element in order of abundance, and constitutes about 0.016% of the earth's crust. It is a fairly common minor constituent of igneous rocks but there are singularly few deposits which qualify with respect to concentration, size and accessibility for commercial interest. The most important sources of the metal are the mixed sulfide ores containing pentlandite, $(Fe,Ni)S$; nickel-bearing pyrrhotite, Fe_5S_6 to $Fe_{16}S_{17}$; and nickel-bearing chalcopyrite, $CuFeS_2$. Ores of this type are mined on a large scale in Canada (Sudbury, Ont., and Lynn Lake, Man.), and to a lesser extent in the Petsamo district of Finland, ceded to the U.S.S.R. during World War II. Minor deposits of nickel-bearing sulfide ores occur in Norway, China, India, Alaska and the United States (Missouri), some production being achieved from the last source. Oxide ores ranging from hydrous magnesium silicates, garnierite, $(Ni,Mg)SiO_3 \cdot nH_2O$ (varieties), to nickel-bearing iron oxide (laterite) have become an increasingly important source of the metal since World War II. The former comprise the important ores of New Caledonia and also are found in the United States (Oregon). The latter occur in Cuba, the Philippines, Indonesia, Brazil and Venezuela.

Metallurgy.—The extractive metallurgy is fairly complex and costly; it underwent rapid changes during and immediately following World War II. The nickel-bearing sulfide ores of Canada, which are embedded in a matrix of basic rock, are first ground and carried through a series of flotation and magnetic separation processes. In the operations of the International Nickel company, three distinct concentrates are isolated for separate processing: nickel-bearing iron sulfide, copper-bearing nickel sulfide and copper sulfide. The nickel-bearing iron sulfide is desulfurized in a fluid-bed roaster, reduced with carbon monoxide and hydrogen in a rotary kiln and then leached with ammonia-carbon dioxide solution to remove the nickel. The residue from the extraction is sintered (formed into solid mass without completely melting) and sold as iron ore pellets to the steel industry. The nickel is recovered as a basic carbonate when the final solution is treated with steam. The copper-bearing nickel sulfide is partially desulfurized in multiple-hearth roasters (*see* COPPER: *Commercial Production Processes: Roasting*), melted and cooled under specially controlled conditions which allow subsequent magnetic and flotation separations into three concentrates: nickel sulfide, copper sulfide and precious metals. The nickel sulfide is sintered for direct sale to the alloy markets, and for further refining, both electrolytically and by the carbonyl process. (*See* CARBONYLS, METAL.)

Nickel-bearing sulfide ores are also treated to a lesser extent by the Hybinette process which involves selective leaching of the copper with sulfuric acid from a nickel-copper matte derived from a flotation concentrate. The crude products are refined by a combination of electrolytic and cementation techniques (*see* CEMENTATION). Flotation concentrates from nickel-bearing sulfide ores are also leached directly in water or ammonia under aeration at elevated pressures and temperatures. The nickel in the resulting salt solutions is recovered directly as a salable powder by treatment with hydrogen gas at elevated temperatures and pressures.

The silicate ores of New Caledonia are largely treated by a matte smelting process. The ore is fused with calcium carbonate, calcium sulfate and coke to yield a nickel-iron sulfide concentrate which is further refined by smelting to eliminate the iron in a siliceous slag, and yield ultimately fairly pure nickel metal. Some of the New Caledonia ores, as well as those from Oregon in the United States, are treated by electric smelting to yield ferronickel which can be sold directly to the steel industry.

Oxide, or lateritic, ores can be reduced in multiple-hearth furnaces and then selectively leached with ammonia-carbon dioxide solutions. The ammonia is recovered efficiently for reuse by steaming the solution which results from leaching, while the nickel is simultaneously precipitated as the basic carbonate. The latter is calcined to nickel oxide for direct sale, or for further processing to nickel-oxide sinter or ingot nickel. Nickel can also be extracted from lateritic ores by direct leaching with sulfuric acid solution at elevated pressure and temperature. A sulfide precipitate produced from the leach solution then can be chemically refined for the production of metallic nickel.

Physical Properties.—Nickel has an atomic number of 28 and occurs in Group VIII of the periodic arrangement of the elements, after iron and cobalt and above palladium and platinum. It resembles iron in strength and toughness but is more like copper,

Physical Constants of Nickel

Density, g./c.c.	8.9 (20° C.)
Melting point, ° C.	1,455
Boiling point, ° C.	2,900
Specific heat, cal./g./° C.	0.1095 (18° C.) 0.1340 (1,360° C.)
Latent heat of fusion, cal./g.	73.8
Coefficient of expansion, cm./cm./° C.	0.0000129 (25°–100° C.) 0.0000135 (375°–1,000° C.)
Thermal conductivity, cal./cm./cm.²/sec./° C.	0.142 (18° C.)
Hardness, Brinell number	85 (99.99% Ni, annealed) 210 (99.4% Ni, cold-rolled)
Atomic radius, Å (angstrom unit = 10^{-8} cm.)	1.24
Ionization potential, volts	7.61 (I), 18.2 (II)
Electrode potential, molal, volts	+0.231 (25° C.)
Electrical conductivity, basis copper = 100%	16%
Resistivity, microhm-cm.	7.8 (20° C.)
Magnetic permeability, μ	110 (initial) 600 (maximum)
Curie temperature, ° C.	360
Tensile strength, lb./in.²	46,000 (99.99% Ni, annealed) 105,000 (99.4% Ni, cold-rolled hard temper)

which follows it with atomic number 29, in resistance to oxidation and corrosion. This combination of useful properties accounts for many of its applications. Nickel has an atomic weight of 58.71 and consists of the following stable isotopes:

Mass number	58	60	61	62	64
Per cent abundance	67.76	26.16	1.25	3.66	1.16

Uses of Nickel in Alloys and as the Metal.—More than 50% of the nickel produced is normally incorporated in alloys with iron. Nickel steels (0.5%–10% nickel) possess special properties of strength and toughness and are used in great quantities in the manufacture of automobiles, trucks, buses, ships, airplanes, railway locomotives and cars and special parts for most types of transportation equipment. They are also used in agricultural equipment, machine tools, mining and excavating machinery, oil well and refinery equipment, steel mill machinery, power-generating equipment and many types of steel construction. Stainless steels (2%–26% nickel) are resistant to corrosion, tarnish and stain and are used extensively wherever these properties in association with strength and toughness are required, as, for example, in transportation equipment such as streamlined trains, airplanes and truck tanks; kitchen equipment, tableware and cooking utensils; and in equipment for the chemical and food-processing industries, textile and paper mills and oil refineries. Heat-resistant steels (2%–26% nickel) are used to meet the high-temperature requirements of furnace and other equipment parts for the glass, ceramic, metal and chemical manufacturing industries. Many other alloys with iron such as the nickel cast irons (1%–5% nickel) meet special needs in the manufacture of metal equipment. About 25% of the nickel produced is used in high nickel alloys. Those with copper (65%–70%) have desirable physical properties and are highly resistant to corrosion. They are used in building, chemical and food-processing equipment and in marine and power-generating equipment. Considerable quantities are also incorporated in cupronickel alloys (2.5%–45% nickel), which are used for condenser tubes and saltwater lines, and in heat-resisting alloys (commonly 78% nickel, 14% chromium, the balance iron and minor elements). They retain their strength, toughness and resistance to oxidation and corrosion at high temperatures, and are therefore particularly useful for jet engine parts and other advanced propulsion systems. Electrical resistance alloys (80%–85% nickel) are used in heating elements, pyrometers, rheostats and other electrical controls. Magnetic alloys (29%–90% nickel), nonmagnetic alloys (8%–27% nickel), permanent magnet alloys (14%–32% nickel), high permeability alloys (45%–80% nickel) and controlled expansion alloys (30%–60% nickel) have been developed for many diverse applications. Nickel coinage (25%–100% nickel) has been adopted in many countries and the so-called nickel silvers (10%–30% nickel, the balance primarily copper and zinc) are used in many familiar articles such as plated silverware stock, slide fasteners, decorative hardware and jewelry. Many other alloys are in use and new nickel alloys are constantly being developed for changing industrial needs.

The fabrication of many modern nickel-based alloys has presented severe technological problems. Techniques developed to solve these problems include: the precision casting of small complex parts by a modification of the cire perdue (investment or precision casting) process, long known to sculptors, using wax or frozen mercury; extrusion with the help of molten glass as a lubricant; and various applications of powder metallurgy. Thoria dispersion (or TD) nickel, composed of 98% nickel and 2% thorium oxide, is produced by a process combining colloidal chemistry and powder metallurgy to form sintered billets that can be extruded and drawn into bars for fabrication into tubing, turbine vanes and blades and other parts for high-temperature service (1,800°–2,400° F.; about 982°–1,316° C.). (*See* ALLOYS; NICKEL-CHROMIUM STEELS; NICKEL STEEL; STEELS, ALLOY.)

About 20% of the nickel produced is normally used directly as the virtually pure metal. It is employed in equipment for the food-processing, chemical, and radio, television and electronic industries. Nickel, as well as stainless steel and other nickel alloys, is used to clad steel and provides, in an economical way, a protective coating which is markedly effective against the corrosive action of chemicals. It is similarly used in electroplating, where it is particularly useful to secure protection from atmospheric corrosion and is kept free from tarnish by a thin layer of chromium. Thin nickel deposits claimed to possess good corrosion resistance may also be produced nonelectrolytically by immersing the article in a hot aqueous solution containing, inter alia, Ni^{2+} and hypophosphite ions.

Chemical Properties and Compounds.—The 28 orbital electrons of nickel are distributed as follows: $1s^2$, $2s^2$, $2p^6$, $3s^2$, $3p^6$ $3d^8$ and $4s^2$. The two electrons in the highest energy level (4s) are readily yielded to form a stable, doubly charged cation. The electrode potential for this reaction is +0.231 v., placing nickel above hydrogen in the electromotive series in the following position: Co, *Ni*, Sn, Pb, H. The metal reacts slowly with strong acids under ordinary conditions to liberate hydrogen and form Ni^{2+}. The salts formed are slightly acid and yield a precipitate of hydrous nickel oxide when the pH of dilute solutions is raised above about 6.7. The metal is uniquely resistant to the action of alkalies and is frequently used for containers to handle concentrated solutions of sodium hydroxide. The element exhibits only a minor tendency to assume the univalent or tervalent states and such ions are not stable in aqueous solution. The third shell contains only 16 electrons, lacking 2 of the stable inert gas arrangement, and many of the compounds involving special valence forces can be attributed to this electronic structure.

Nickelous oxide, NiO, occurs in nature in small quantities as the mineral bunsenite and can be prepared by heating a variety of nickel compounds in air. It can be reduced to nickel by heating with carbon, hydrogen and other reducing gases. It is soluble in strong acids unless it contains impurities or has been sintered, in which case fusion with $KHSO_4$ may be necessary. Nickel oxide is used in the preparation of nickel alloys, in ground-coat enamels for its beneficial effects on adherence and in colouring ceramics and glass. Nickelous hydroxide, $Ni(OH)_2$, is obtained as a light-green precipitate when nickel salts are treated with alkalies. It is readily soluble in acids and ammonium hydroxide, yielding in the latter case complex ammine ions. It may be reduced with hydrogen at sufficiently low temperatures to yield active nickel catalysts and is incorporated in the Edison nickel-iron alkaline storage battery where it yields higher valent hydrous oxides when the battery is charged. Basic nickel carbonates result from the reaction between nickel salts and alkali carbonates. If a mixture of alkali and hypohalite is used, higher hydrous oxides of variable composition are yielded as black precipitates. These products are all converted to nickelous oxide, NiO, on complete dehydration and yield exclusively the double-charged nickel cation on solution in acids. Nickel forms a related series of compounds with sulfur. In addition to the commercially important mixed sulfide ores already mentioned, such minerals as millerite (NiS) and polydymite (Ni_3S_4) belong to this group of compounds. Nickelous sulfide, NiS, is highly insoluble and is readily precipitated when nickel salts are mixed with alkaline sulfide in aqueous solution. Other sulfides, such as Ni_3S_2, can be obtained by direct reaction of sulfur and sulfur compounds with the metal and its derivatives.

Nickel sulfate is the most familiar salt. It can readily be prepared by dissolving nickel metal or nickelous hydroxide in sulfuric acid. It is quite soluble in water (140 g. Ni per 1,000 ml. water at 0° C., 761 g. at 100° C.) and can be purified by recrystallization, to yield the hexahydrate $NiSO_4 \cdot 6H_2O$. This salt is widely employed in plating baths and in dips for steel vessels which are to be coated with vitreous enamel and commonly serves as a reagent for the preparation of nickel catalysts. The nickel halides and nickel nitrate can be similarly prepared and purified. Nickel chloride crystallizes as the hexahydrate, $NiCl_2 \cdot 6H_2O$, and becomes anhydrous when heated above 140° C. Nickel nitrate hexahydrate $Ni(NO_3)_2 \cdot 6H_2O$, dissolves in its own water of crystallization at about 57° C., readily dehydrates at higher temperatures and decomposes at about 300° C. to yield NiO in air, or pyrophoric nickel when heated in a reducing atmosphere. It is used in the preparation of special nickel catalysts and powders and, along with the chloride, is also used to some extent in nickel plating. Most nickel salts form double compounds with other salts, and co-ordination

complexes with ammonia. Nickel also forms co-ordination complexes with alkali cyanides and in this behaviour exhibits properties similar to those of palladium and platinum.

Nickel readily forms salts with organic acids, either by direct reaction between nickelous hydroxide and the acid or by double decomposition between suitable salts. Nickel formate, $Ni(HCOO)_2$, which is one of the most familiar of these, is unique in that it decomposes at about 240° C. to give off hydrogen and carbon dioxide, leaving a residue of finely divided nickel which is particularly useful as a hydrogenation catalyst. The higher fatty acid salts, such as the stearate and oleate, are water insoluble and exhibit colloidal properties typical of the metal soaps when dispersed in organic liquids.

Nickel forms a series of compounds in which co-ordination or secondary valence forces are involved in addition to those of the usual salt structure. The highly insoluble, striking red derivative with dimethylglyoxime, commonly precipitated in nickel analyses, is a characteristic inner-complex compound involving a chelate ring. This derivative is nonpolar in character, highly insoluble in water, but somewhat soluble in chloroform and other organic solvents. It sublimes without decomposition when heated in vacuo, but is readily converted quantitatively to NiO on strong heating in air.

Nickel carbonyl, $Ni(CO)_4$, is an unusual compound in that it contains a neutral nickel atom surrounded by four co-ordinately bound carbonyl groups. It can be prepared by treating finely divided metallic nickel with carbon monoxide; sulfur acts as a catalyst for this reaction. The product is a colourless mobile liquid with a high vapour pressure and is poisonous if inhaled. It boils at 43° C. and begins to decompose at 60° C. or less, depending on the conditions, to metallic nickel and carbon monoxide. A fine nickel powder may be prepared in this manner, or pellets may be built up on nuclei of nickel as in the Mond process. A bright nickel mirror or nickel plate may also be obtained and nickel carbonyl can serve as a source of reactive carbon monoxide in certain organic syntheses. (*See* CARBONYLS, METAL.)

Analytical.—Nickel is precipitated in the ammonium sulfide group along with cobalt, manganese, zinc and iron in systematic analyses. The nickel and cobalt sulfides remain as undissolved residue after the precipitate is extracted with dilute hydrochloric acid. Nickel may be identified by its red precipitate with dimethylglyoxime, or its brown borax bead. In quantitative analysis nickel is usually isolated and weighed as the dimethylglyoxime complex. It may also be determined by titration with potassium cyanide solution, electrolysis of a strongly ammoniacal solution, or polarographically.

Uses of Nickel Compounds.—Nickel compounds have been used mainly in electroplating, in the production of nickel catalysts, in ground-coat enamels, in storage batteries of the Edison type and in the production of special nickel powders. Many nickel compounds exhibit insecticidal, fungicidal and bactericidal action, but have not received wide practical use because of the availability of effective cheaper materials. Ingested nickel is relatively nontoxic and any quantities that might be picked up incidentally through the use of nickel or nickel-alloy cooking utensils or in fats hydrogenated over nickel catalysts are considered to be without physiological action.

Nickel Catalysts.—Substantially more than 2,000,000 lb. of the metal are used in catalytic applications each year. Catalytic nickel can be prepared by many different methods. Nickelous hydroxide and basic carbonates, nickel nitrate, formate and various other organic compounds yield, on thermal decomposition at moderate temperatures in a reducing atmosphere, finely divided nickel in a highly active form. Nickel sulfate and other soluble salts are frequently the starting reagent. The precipitates obtained when they are mixed with alkalies in aqueous solution, frequently in admixture with carrier materials such as diatomaceous earth, are washed, dried and reduced. Nickel formate yields active nickel directly when it is decomposed without access to air, such as under oils which are to be treated. Nickel alloys containing a metal which can be selectively dissolved away, such as the nickel-aluminum preparations of M. Raney which yield on treatment with sodium hydroxide soluble sodium aluminate and an active nickel residue, are commonly employed. Nickel catalysts are most frequently utilized in hydrogenating unsaturated organic compounds. The most familiar application is the hydrogenation of fats and oils, in the process known as fat hardening. A fraction of 1% of active, finely divided nickel suffices to catalyze the addition of hydrogen to unsaturated compounds in vegetable, animal and fish oils, converting them from liquids to solids with more desirable physical properties and greatly improved chemical stability. The nickel is recovered by filtration and may be reused or may be employed in continuous processes. Many millions of pounds of natural oils are treated annually in this manner for use in edible products such as shortenings and oleomargarine, in soaps and numerous industrial preparations. Nickel catalysts are also extensively used in the synthesis of organic chemicals and pharmaceuticals, in petroleum chemistry and gaseous fuel production. Although the quantity of nickel used in chemical operations is dwarfed by the tonnages which go into structural applications, it has become a reagent of great importance in chemical industries.

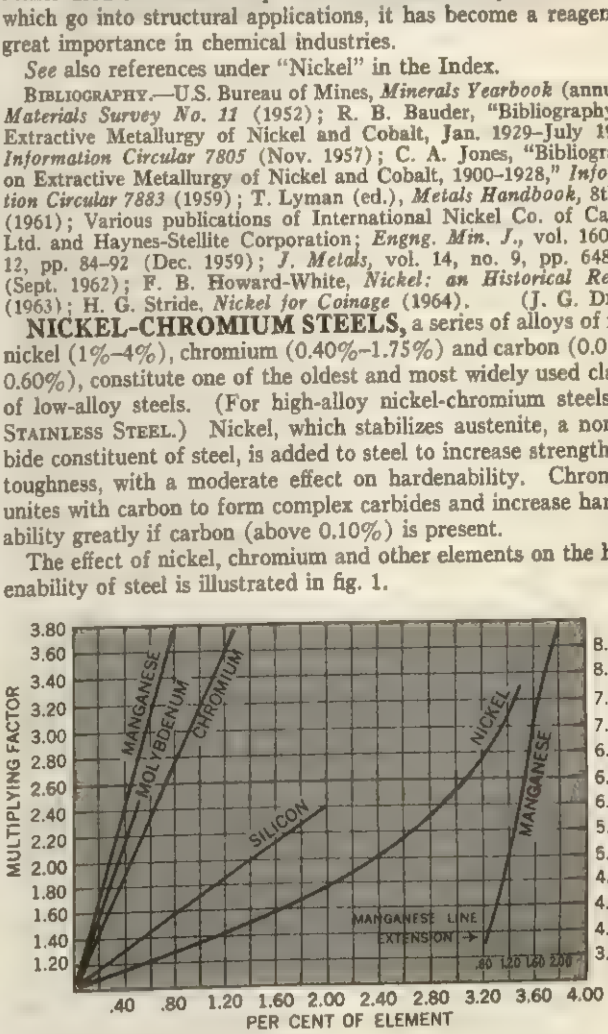
NICKEL-CHROMIUM STEELS, a series of alloys of iron, nickel (1%–4%), chromium (0.40%–1.75%) and carbon (0.05%–0.60%), constitute one of the oldest and most widely used classes of low-alloy steels. (For high-alloy nickel-chromium steels *see* STAINLESS STEEL.) Nickel, which stabilizes austenite, a noncarbide constituent of steel, is added to steel to increase strength and toughness, with a moderate effect on hardenability. Chromium unites with carbon to form complex carbides and increase hardenability greatly if carbon (above 0.10%) is present.

The effect of nickel, chromium and other elements on the hardenability of steel is illustrated in fig. 1.



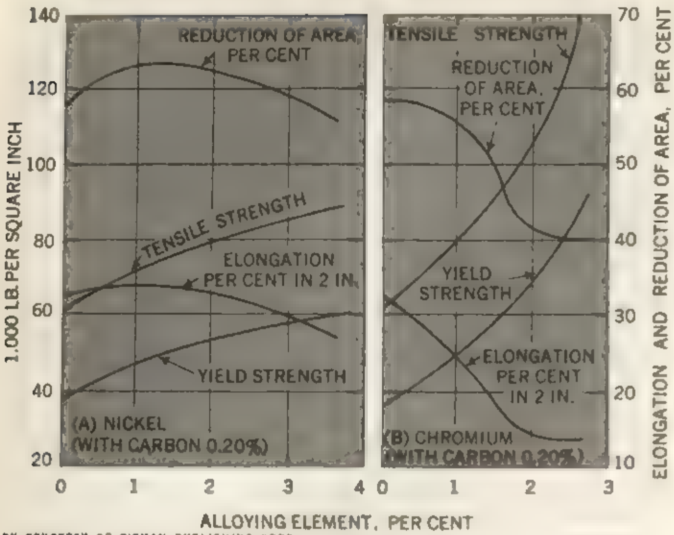
BY COURTESY OF AMERICAN IRON & STEEL INSTITUTE

FIG. 1.—HARDENABILITY MULTIPLYING FACTORS FOR A VARIETY OF ALLOYING ELEMENTS

The low-alloy grades of nickel-chromium steels (1.0% to 2.0% nickel and 0.5% to 1.0% chromium) have hardening characteristics similar to those of other low-alloy steels. They are hardened by water quenching up to 0.40% carbon and oil-quenched with higher carbon contents. The higher-alloy grades (3.00% to 4.00% nickel and 0.50% to 2.00% chromium) may be air- or oil-quenched, depending on the composition and size of cross section.

The effect of nickel and chromium on the physical properties of air-cooled, hot-rolled 0.20% carbon steel for a 0.05 to 0.75 in. section is illustrated in fig. 2.

Nickel-chromium steel may be produced in an electric or open-hearth furnace. Nickel is not oxidized in the molten bath and



BY COURTESY OF PITMAN PUBLISHING CORP.

FIG. 2.—EFFECT OF (A) NICKEL AND (B) CHROMIUM ON THE TENSILE PROPERTIES OF ROLLED CARBON STEELS

therefore yields 100% recovery (*see* NICKEL STEEL). Chromium presents a different problem because it is oxidized and enters the slag under normal basic open-hearth operations.

It is, therefore, not recovered from scrap in this operation, and additions must be made in the bath after it is thoroughly deoxidized or to the ladle during the tap. Recovery of chromium is possible, however, in the electric furnace with proper slag manipulation; that is, using a reducing slag or adding silicon or chrome silicide (reducing agents) to the furnace bath following an oxidizing condition to reduce the Cr_2O_3 in the slag to chromium and return it to the metal portion. Nickel-chromium steel may also be made in an acid open-hearth or acid electric furnace, using raw materials free from undesirable elements that cannot be removed by these processes. Nickel-chromium steels may be poured into ingots or castings; and the usual deoxidizer, as in nickel steel, is silicon, which is added in the ladle to about 0.25% of the final chemical analysis of the heat.

Ingots are stripped and placed in soaking pits as soon as they are solidified to prevent cooling cracks, and semifinished products, such as blooms, slabs and shapes, are stacked close together to prevent cooling cracks. Nickel-chromium steels are subject to flakes or hair cracks, as are many other air-hardening steels. Thorough deoxidation, slow pouring at correct temperatures and slow heating and cooling assist in avoiding flakes.

Nickel-chromium steels are used for important parts that are to be case-hardened or for highly stressed forgings. They are also widely used for heavy castings, such as those for bridges, locomotives and rolling-mill machinery, and for abrasion-resisting castings, such as power-shovel teeth and impact hammers.

The accompanying table shows a range of about 60 A.I.S.I. and S.A.E. nickel-chromium steels used in the United States.

Steels of the 3100 series, such as 3115 and 3120, are low-cost carburizing grades used for piston rings, automotive power train gears, oil-well-bit reamer cutters and many other small, case-hardened parts. The S.A.E. 3200 steels containing 2% nickel and 1% chromium are most often used in the high-carbon ranges. These steels are superior to the 3100 series in tensile properties and are used for automobile drive and axle shafts, master connecting rods of radial aircraft engines and many highly stressed keys and pins.

Steels of the A.I.S.I. 3300 series, containing around 0.30% or 0.40% carbon, develop mechanical properties superior to those of the lower alloy content nickel-chromium steels, particularly in sections over $3\frac{1}{2}$ in. They are therefore used extensively for forgings and bars that require rigid mechanical properties, such as large rocker arms and connecting rods. The S.A.E. 3400 series steels exhibit excellent resistance to fatigue, combined with good strength and ductility, which is especially valuable in parts likely to be subject to occasional overstressing from vibration or other causes. A.I.S.I. 3450 is used for heavy-duty gears of medium section in machine-tool construction.

Many nickel-chromium steels have been developed containing small additions of molybdenum, which are more complex steels (*see* table) with outstanding properties. The addition of molybdenum increases depth-hardening properties which makes it possible to develop strength and hardness in large sections equal to those secured in small sizes of other steels. Another characteristic of the nickel-chromium-molybdenum steels that contributes to their usefulness is high-hardness-machinability properties. Some compositions may be machined with Brinell hardnesses exceeding 400. These steels also show high resistance to creep up to about 1,000° F., and find application in valves and fittings in steam power plants.

Steels with about 0.55% carbon, 0.65% manganese, 2.00% nickel, 0.90% chromium and 0.20% molybdenum are used for roller bearings where ductility is required along with high hardness and fatigue resistance.

Keating, *Chromium-Nickel Austenitic Steels* (1956). (N. B. Ma.)

NICKEL SILVER comprises a range of alloys of copper nickel and zinc which are silvery in appearance but contain no silver. Its composition varies from 7% to 30% nickel, the alloy most widely used being "18% nickel silver" (18% nickel, 62% copper, 20% zinc). In general the zinc content is lowered as the nickel is increased, the copper content varying between 53% and 63%.

The importance of these alloys lies in their colour, ductility good mechanical properties and suitability for working in a wide variety of cast, rolled and extruded or drawn shapes. The addition of 1%–2% lead improves machining properties. Such alloys resist corrosion better than does brass but tarnish slowly through the action of sulfur in the air. Their colour ranges from nearly white in the 30% alloy to pale brassy yellow in the alloys with low nickel content.

A natural alloy known as paktong (white copper), smelted by the Chinese from copper-nickel ores, was one of the first alloys used by man. It was later improved by the addition of zinc ores and was imported into Europe by the East India company. Not until the 1840s was the alloy made in Europe by mixing the three metals and it was known as German silver until 1914. After an electroplating plant was set up in Birmingham in 1844 German silver was found very suitable as a basis for silver plating.

Nickel silver is used extensively for electroplated table and ornamental silverware, for jewelry, for architectural and ornamental metalwork, for some food and chemical equipment and for marine and plumbers' fittings. In hard-rolled strip form it is used for spring elements, especially in electrical and telephone relays. (P. E. G.)

NICKEL STEEL. Nickel steel was first produced by J. F. Hall of England and M. Marbeau of France about 1885, each working independently. The grades commercially used are an alloy of nickel (0.20%–5.00%), carbon (0.10%–0.60%) and the remainder

iron. The primary reason for adding nickel to steel is to increase its strength, toughness, depth hardness, and resistance to fatigue. These properties may be gained with small percentages of nickel (often referred to as an austenite former), which lower the eutectoid ratio (1% of nickel = 0.042% carbon) and tend to suppress transformation of austenite during cooling. In effect this results in a full-hardened steel with great strength and toughness, even after slow cooling, which is not possible with ordinary carbon steel.

Higher percentages of nickel than those specified above are not used commercially in nickel steel (*see* STAINLESS STEEL) because a martensitic structure, such as 0.40% carbon and 7% nickel, will result which has low elongation and shock-resistant values and is difficult to work and machine. (*See* also STEELS, ALLOY.)

Nickel steel may be produced in the electric or open-hearth furnace in the same manner as carbon steel, except that cleaner scrap is generally used and greater control exercised because of the economic risks. Nickel is not oxidized in the molten bath. It is, therefore, completely recovered from nickel-bearing scrap, and nickel may be added to meet specification early or late during the making of the heat.

Nickel steel may be teemed into ingots or castings; and the usual deoxidizer is silicon, which is added in the ladle to about 0.25% of the final chemical analysis of the heat. Ingots are stripped as soon as solidified and placed immediately in soaking pits to prevent cooling cracks.

The hot-working temperatures vary slightly from 2,200° F., depending on the chemical composition. Blooms, slabs, plates and shapes are stacked close together and protected from drafts while cooling. Surface imperfections are removed from nickel steel in the semifinished state and in the finished state if permitted by the user.

Industrial Uses.—By using high-strength steel, structures can generally be lightened in weight; for this reason, nickel steels and other alloy steels are widely used in the automotive and railroad industries. It is estimated that the U.S. automotive industry alone consumes 60% of all alloy-steel bar stock used in the country for the production of gears, shafts, roller bearings, nuts, bolts and various forgings. The weight saving over carbon steel by the use of nickel-alloy steel may be as much as 50%. For example, the weight of the entire rear-end assembly of an automobile may be reduced one-half by using smaller axles, housings and bearings of nickel steel and at the same time be as strong as twice its weight of carbon steel.

In steam locomotives, nickel steel was used for axles, boilers and firebox plates and frame castings. In diesel locomotives it is used for gears, generator roofs and side sheets and frames. In marine propulsion, such steels are used for shafts and in reduction-gear assemblies. In aircraft it is used for landing-gear parts and power-transmitting parts of reciprocating engines. Nickel steel was chosen for the forging of the world's largest supersonic wind tunnel at the air force research centre at Tullahoma, Tenn., with the following composition 0.28% carbon, 0.65% manganese, 2.85% nickel, 0.35% molybdenum and 0.07% vanadium. Nickel steel has also been used in long-span bridges to reduce dead weight and increase the pay load (for example, the George Washington bridge across the Hudson river at New York city and the San Francisco-Oakland bridge).

TABLE I.—*Effects of Nickel on Hardness and Low Temperature Strength Using a 0.20% Carbon Normalized Steel*

Nickel (%)	Brinell hardness	Charpy impact resistance in ft.-lb. at	
		Room temperature	-50° F.
0.0	127	80	7
1.0	146	94	30
2.0	155	88	35
3.0	168	88	40
4.0	187	75	50

Although the greater portion of nickel steel is employed for rolled or forged products, a generous quantity is used for castings. Cast-nickel alloys respond to heat treatment and give high values for strength and hardness.

A few uses are railroad passenger-car truck frames, rolling-mill rolls, heavy-cast machinery gears, crusher-jaw castings, impact hammers and power shovels.

One of the outstanding characteristics of nickel steels is resistance to embrittlement at low temperatures, for which reason it is utilized in chemical equipment for subzero operations. This fact, plus the effect of nickel on hardness, is shown in Table I.

Table II illustrates the wide range of these steels used in the United States.

Steel A is an inexpensive water or oil hardening steel for parts of moderate importance, steel B can be oil-quenched direct from the carburizing heat for a tough core and file-hard case; it has good machining properties and is widely used for roller bearings, gears, piston pins and drive shafts. Steel C usually is given a more elaborate heat treatment for a strong, tough core; it is used for gears, shafts, and machine parts requiring extra toughness as well as surface hardness and constancy of dimension. Steel D is hard to work but after proper case hardening gives parts having extreme hardness and resistance to shock; examples are aircraft engines, crankshafts, truck, bus and tractor transmission, and differential gears.

TABLE II.—*Range of Analyses of Nickel-Bearing Steels*

	Low-nickel		Medium-nickel	High-nickel
	A (%)	B (%)	C (%)	D (%)
Carbon	0.10–0.40	0.06–0.43	0.10–0.50	0.09–0.20
Manganese	.30–1.20	.25– .90	.40– .90	.40– .60
Nickel	.20–1.00	1.40–2.00	3.25–3.75	4.50–5.25
Molybdenum	—	.15– .30	None or .20– .30	—

Great strides had been made by the 1960s in finding substitutes for nickel in steel. Manganese, boron and nitrogen had been proved possible substitutes. Many high-nickel alloys had been developed containing up to 95% nickel. Some uses of these are lead-in wire for light bulbs and electron tubes, thermocouples, low-coefficient-of-expansion material, alloys that resist chemicals and other corrosive mediums and magnets.

NICOBAR ISLANDS, a group of 12 inhabited and 7 uninhabited islands in the Bay of Bengal, between Sumatra, Indon., and the Andaman Islands (*q.v.*). The Andaman and Nicobar Islands together constitute a Union territory of the Republic of India under a chief commissioner, with its capital at Port Blair (*q.v.*) in the Andamans. The aggregate area of the Nicobars is 627 sq.mi., and Great Nicobar (Loöng), the largest and southernmost of any size, has an area of 333 sq.mi. Principal of the central group of islands are Camorta and Nancowry (Nankauri), between them being a landlocked shelter called Nancowry harbour. Chief island of the northern group is Car Nicobar (Pu), area 49 sq.mi. Some of the islands have mere flat coral-covered surfaces; others, again, are hilly, Great Nicobar rising to 2,105 ft. On that island there are considerable and beautiful streams, but the others generally are badly off for fresh surface water. In 1961 the inhabitants of the Nicobar Islands numbered approximately 14,500, Car Nicobar being by far the most densely populated island.

Geology and Climate.—The Nicobars form part of a great submarine mountain chain linking the Arakan Yoma range of Burma, through the Andamans and Nicobars, with the main mountain chain of Sumatra. There are early geological reports issued by a Danish scientific expedition of 1846 and an Austrian expedition of 1858. Later work by the Indian geological survey revealed

a structure of a complex anticlinorium like that of the Arakan Yoma range with intrusive masses of serpentine and gabbro probably of Cretaceous age, but the folded sedimentaries are mainly Tertiary. Earthquakes of great violence were recorded in 1847 and 1881 (with tidal wave), and mild shocks were experienced in Dec. 1899.

Being situated between latitude 6° and 10° N. of the equator, the islands have a nearly equatorial climate. They are exposed to both monsoons, and smooth weather is experienced only from February to April and in October. Rain falls throughout the year, generally in sharp, heavy showers. The rainfall varies from 90 to 135 in., and the shade temperature from 18° to 33° C. (64° to 92° F.).

Vegetation and Animal Life.—The vegetation of the Nicobars has not been subjected to a systematic examination by the Indian forest department like that of the Andamans, and indeed the forests are inferior in economic value to those of the more northerly group. There are fruit trees, such as the coconut (*Cocos nucifera*), the betel nut (*Areca catechu*), and the Nicobar breadfruit (*Pandanus leram*), a thatching palm (*Nipa fruticans*) and various timber trees of some commercial value, but only one timber tree, the black chuglam (*Myristica irya*), would be considered first class in the Andamans. The palms of the Nicobars are exceedingly graceful.

The mammals are not numerous: in the southernmost islands are a small monkey, the crab-eating macaque (*Macaca irus*), a tree shrew (*Tupaia nicobarica*), rats and mice, bats and the Nicobar flying fox. It is doubtful if the wild boar is indigenous; cattle when introduced and left, have speedily become "wild." The birds, of which there are many kinds, show strong Indian affinities. Notable among those found in the islands are the megapode (*Megapodius nicobaricus*), characteristic of the Australian region, the edible-nest-building swift, the hackled and pied pigeons, a parakeet (*Palaeornis caniceps*) and an oriole. Snakes, lizards and chameleons, crocodiles, turtles and an enormous variant of the edible Indian crab are numerous; butterflies and other insects have not yet been systematically collected. The freshwater fish are reported to be of the types found in Sumatra.

History.—The situation of the Nicobars along a line of an ancient trade route caused them to be reported by traders and seafarers through historical times. In the 17th century the islands began to attract the attention of missionaries. At various periods, France, Denmark, Austria and Great Britain all had more or less obscure rights to the islands, the Danes being the most persistent in their efforts to occupy the group, until in 1869 they relinquished their claims in favour of the British, who at once began to put down the piracies of the islanders, and established a penal settlement, which was withdrawn in 1888. Car Nicobar in the north and Camorta in the centre became the principal ports of the group.

In 1942, during World War II, the Nicobar Islands were occupied by Japanese forces, who developed Car Nicobar as a big supply base. In 1945 the islands were reoccupied by the Allies. With the Andamans they passed to India on the establishment of Indian independence. (L. D. S.)

The People.—The Nicobarese are probably a mixture of Malay and Burmese (Talaing) strains. They are of relatively short stature (average height of adult male, 5 ft. $3\frac{3}{4}$ in.) and sturdy build; hair may be slightly wavy or curly, scanty on face and body; brachycephaly is usual. The language, which has several dialects, belongs to the Mon-Khmer group.

The political unit is the village. There are hereditary headmen who govern with a council of elders; the power of the headman depends on his personality, and public opinion is the final arbiter. Land is held by the community, but there is private ownership of fruit and coconut trees. The status of women is high; they inherit and own property, and girls have considerable freedom in the choice of a husband. The marriage tie is loose, and separation (which ends the marriage) is frequent. Polygamy is rare and is confined to the rich. A man who feels himself offended or ill-used will express his sense of grievance and put his enemy to shame by destroying his own property or even by self-mutilation.

Clothing is scanty. Men wear a belt and a cloth perineal band with a tail behind, perhaps connected with one of their stories of origin—that they are descended from a man who mated with a bitch. Articles of European clothing are now often worn. Houses vary in shape; they are built on piles, with thatched roofs, and are reached by a notched pole. Much cooking is done in them on clay hearths, but there are also separate cookhouses. Special houses are built by communal labour for feasts and meetings. The coconut is the main crop and yams and other vegetables are grown; fish, turtles, pigs and fowl are also important in the diet. Crossbows are used for shooting birds, spears for hunting pigs, spears, nets, traps and poison for fish, harpoons for turtles. The dao (half sword, half chopper) is the universal tool. Canoes are single outriggers with dugout hulls.

The concept of a beneficent creator is known, probably as a result of missionary influence. The indigenous religion consists in belief in a multiplicity of spirits, many of them those of ancestors, who may be friendly (locally) or more frequently malevolent. The latter bring disease and misfortune. There is a class of mediums who can communicate with, and control, the spirits; those causing sickness may be caught and towed out to sea on model rafts. Grotesque carvings of aggressive mien, which are probably regarded as residences for friendly ancestral spirits, are kept in houses to scare away evil spirits. Men can acquire reputations as sorcerers by eccentric behaviour, such as sitting in pig wallows and collecting bristles; they are much feared, and were sometimes killed.

The natives of Chowra, a small island of the central group, act as middlemen for the group. They alone make pottery, with clay obtained from Teressa, and exchange it for canoes made in the southern and central islands, which they trade to the north. Chowra men go to Nancowry to burn shells for lime (used in betel chewing), paying in pots for the privilege.

The Shom Pen of the interior of Great Nicobar may represent an earlier element in the population. They practised a simple type of cultivation, the digging stick being their only implement, and relied heavily on hunting; wild pigs, which they hunted with dogs, were the main quarry. Their only weapon seems to have been a wooden spear. They are now few in numbers and have been considerably influenced by the coastal people.

NICOLAI, CHRISTOPH FRIEDRICH

NICOLAI, CHRISTOPH FRIEDRICH (1733–1811), German author and bookseller who, with Lessing and Moses Mendelssohn, was a leader of the German *Aufklärung* (Enlightenment), was born on March 18, 1733, at Berlin, son of the well-known bookseller, Christoph Gottlieb Nicolai (d. 1752). In 1749 he went to Frankfurt an der Oder to learn his father's business, finding time also to become acquainted with English literature.

In 1752 he returned to Berlin, where he began to take part in literary controversy by defending Milton against the attacks of J. C. Gottsched. Nicolai's *Briefe über den jetzigen Zustand der schönen Wissenschaften in Deutschland*, published anonymously in 1755, were directed against both Gottsched and Gottsched's Swiss opponents, J. J. Bodmer and J. J. Breitinger; his enthusiasm for English literature won him the friendship of Lessing and Mendelssohn. With Mendelssohn he established the periodical *Bibliothek der schönen Wissenschaften* (1757–60); and with Lessing and Mendelssohn *Briefe, die neueste Literatur betreffend* (1759–65); from 1765 to 1792 he edited the *Allgemeine deutsche Bibliothek*. The *Bibliothek* was the organ of the so-called "popular philosophers," who warred against authority in religion, and against what they conceived to be extravagance in literature, and Nicolai showed a complete incomprehension of the new movement of ideas represented by Herder, Goethe, Schiller, Kant and Fichte.

Of Nicolai's independent works, perhaps the only one with some historical value was his *Charakteristischen Anekdoten von Friedrich II* (1788–92). His romances are forgotten, although *Das Leben und die Meinungen des Magisters Sebaldus Nothanker* (1773–76) and his satire on Goethe's Werther, *Die Freuden des jungen Werthers* (1775), had a certain reputation in their day.

Between 1788 and 1796 Nicolai published in 12 volumes a *Beschreibung einer Reise durch Deutschland und die Schweiz,* which bore witness to the narrow conservatism of his views in later life. He died in Berlin on Jan. 8, 1811.

Nicolai's *Bildniss und Selbstbiographie,* edited by M. S. Löwe, was published in the *Bildnisse jetzt lebender Berliner Gelehrter* (1806).

BIBLIOGRAPHY.—L. F. G. von Göckingk, *F. Nicolai's Leben und literarischer Nachlass* (1820); J. Minor, *Lessings Jugendfreunde,* in J. Kürschner's *Deutsche Nationalliteratur,* vol. lxxii (1883); M. Sommerfeld, *F. Nicolai und der Sturm und Drang* (1921); F. Meyer, *F. Nicolai* (1938).

NICOLAI, (CARL) OTTO EHRENFRIED (1810–1849), German composer known for his comic opera *Die lustigen Weiber von Windsor* (*The Merry Wives of Windsor*) based on the comedy by Shakespeare. Born at Königsberg on June 9, 1810, he was exploited by his father in his youth as a prodigy. In 1827 he studied in Berlin and later under G. Baini in Rome, producing from 1838 onward several successful operas in Italy and Vienna. In 1841 he became court conductor in Vienna and founded the Philharmonic society there the following year. In 1848 he was appointed conductor of the opera at Berlin and on March 9, 1849, he produced there *Die lustigen Weiber von Windsor*, which remained one of the most popular comic operas throughout the 19th century. He died in Berlin on May 11, 1849.

See Otto Nicolai, *Tagebücher,* ed. by W. Altmann (1937).

NICOLE, PIERRE (1625–1695), French Jansenist theologian and moralist, was born at Chartres. He studied at Paris, and taught at Port Royal, for which, with Antoine Arnauld and others, he wrote schoolbooks, especially *Logique de Port-Royal.* From 1655 to 1668 he played a decisive part in writing or editing most of the Jansenist pamphlets (*see* JANSENISM). His special contribution to this controversy was the distinction drawn between the *question de droit* (are the doctrines called Jansenist heretical?) and the *question de fait* (did Jansen teach these doctrines?). By answering the first affirmatively and the second negatively, he enabled the Jansenists to pursue their program without openly breaking with the church. From 1669 Nicole devoted his theological talents mainly to the defense of Roman Catholic dogma against the historical criticism of Protestant writers. But his best, and best-known, work is the *Essais de Morale* (4 vol., 1671–78, 10 more posthumously), in which he discoursed, with some humanity of outlook and great penetration of mind, upon the practice and problems of a rigorously Christian ethic in the world of his day. He had no sympathy with advanced mystical speculations. He died in Paris on Nov. 16, 1695.

See C. A. Sainte-Beuve, *Port-Royal,* 5th ed., vol. iv (1888); M. J. F. R.; H. Bremond, *Histoire littéraire du sentiment religieux en France,* vol. iv (1920). (N. J. A.)

NICOLLE, CHARLES JULES HENRI (1866–1936), French bacteriologist, winner of the 1928 Nobel prize in medicine for his discovery that typhus fever (*q.v.*) is transmitted by the body louse, was born on Sept. 21, 1866, at Rouen, where his father, Eugène Nicolle, was professor of medicine. After graduating M.D. at Paris in 1893 he became a member of the Rouen medical faculty, and in 1896 was appointed director of its bacteriological laboratory, where he carried out important work on the preparation of diphtheria antiserum. In 1903 he was appointed director of the Pasteur institute in Tunis, and during his 33 years' tenure of that post the institute became a world-famous centre for bacteriological research and for the production of serums and vaccines to combat many of the most prevalent infectious diseases. His researches on the transmission of typhus culminated in 1909 when he made the discoveries for which he received the Nobel prize. Later he helped to make a clear distinction between classical louse-borne epidemic typhus and murine typhus, which is conveyed to man by the rat flea. He also made valuable contributions to the knowledge of rinderpest, brucellosis, measles, scarlet fever, diphtheria and tuberculosis, and was responsible for many innovations in bacteriological technique. Apart from his scientific activities, Nicolle enjoyed a considerable reputation as a philosopher and as a writer of fanciful stories. In 1928 the silver jubilee of his directorship of the Tunis institute was commemorated by a gold medal, and in 1932 he was elected to a chair in the Collège de France. He died in Tunis on Feb. 28, 1936. (W. J. BP.)

NICOLLS, RICHARD (1624–1672), the first English governor of the province of New York, was born at Ampthill, Bedfordshire, Eng., the son of a barrister, in 1624. A stanch royalist, he served in the army during the English Civil War and followed the Stuarts into exile. In 1664, soon after the Restoration, he was appointed by the duke of York to be governor of the territory in America that was about to be acquired from the Dutch. With a squadron of four vessels he blockaded New Amsterdam and the Dutch capitulated in September without bloodshed. Although Nicolls' commission gave him practically absolute power, the transition from Dutch to English rule was made tactfully and gradually. His rule brought increased freedom to the Dutch but it did not meet the expectations of the English inhabitants for representative government. A legal code known as the "Duke's laws" was issued in 1665 and continued in force until 1683. Nicolls ruled so fairly and well that he was held in high esteem by all. He resigned in 1668, returned to England, and was killed on May 28, 1672, in a naval battle during the Third Dutch War. *See* also NEW YORK: *History.*

See M. Schuyler, *Richard Nicolls* (1933). (RA. MU.)

NICOMACHUS (fl. 4th century B.C.), of Thebes, Greek painter, was a contemporary of the greatest painters of Greece; Vitruvius observes that if his fame was less than theirs, it was the fault of fortune rather than of demerit. Pliny the Elder gives a list of his works, among them a "Rape of Persephone," "Victory in a Quadriga," a group of Apollo and Artemis and the "Mother of the Gods Seated on a Lion." Pliny also says that he was a very rapid worker and used only four colours.

NICOMACHUS, a Neopythagorean philosopher and mathematician whose works had a great vogue, was born at Gerasa in ancient Palestine (modern Jordan) and flourished about A.D. 100. One of his two extant treatises, called *Introductio arithmetica,* sets out the elementary theory and properties of numbers. Numbers are no longer denoted by lines as in Euclid, but are written in the ordinary notation; hence general principles can be stated only with reference to particular numbers taken as illustrations. Nicomachus states a rule about cubes that makes it possible to sum any number of forms of the series of natural cubes beginning from one. His popularity is revealed by Lucian's having a character say, "You count like Nicomachus." A Latin translation by Apuleius of Madauros (born about A.D. 125) is lost; but Boëthius' version survives. The commentators include Iamblichus, Heronas, Asclepius of Tralles, John Philoponus and Proclus. The Greek text was edited by R. Hoche (1866) and the commentaries of Iamblichus and Philoponus by E. Pistelli (1894) and Hoche (1864 and 1864–67), respectively. There is an English translation by M. L. D'Ooge with essays by F. E. Robbins and L. C. Karpinski (1926). Nicomachus' *Enchiridion Harmonices* (ed. by C. Jan in *Musici Scriptores Graeci,* 1895) is on the Pythagorean theory of music. Nicomachus is said to have written *Theologumena arithmetices* (in two books) on the properties of numbers, of which the *Theologumena arithmeticae* edited by F. Ast (1817) contains no more than fragments, at most. (T. L. H.; X.)

NICOMEDES (*c.* 240 B.C.), Greek mathematician, is known only through references to his work by the commentators Pappus (*c.* A.D. 320), Iamblichus (*c.* A.D. 310) and Proclus (*c.* A.D. 450). His date is estimated from the fact that he is said to have compared his work with that of Eratosthenes and that he is referred to by Apollonius, these two men being contemporaries.

Nicomedes seems to have been the inventor of the conchoid, a curve that he used in trisecting an angle and in doubling a cube. The use of this curve to solve the problems of trisecting an angle and duplicating a cube should not be interpreted to mean that these problems can also be handled by the Euclidean instruments of the compass and the straightedge, for this is impossible.

See Ivor Thomas (trans. and ed.), *Selections Illustrating the History of Greek Mathematics,* vol. i (1939–42). (V. SD.; X.)

NICOMEDIA: *see* IZMIT.

NICOPOLIS (VICTORY CITY) **ACTIA** (modern NIKOPOLIS, formerly known as PALAIOPREVEZA, about 4 mi. N. of Preveza,

northwestern Greece), an ancient city of Epirus founded 31 B.C. by Octavian (Augustus) in memory of his victory over Antony and Cleopatra at Actium. The colony, composed of settlers from many neighbouring towns, succeeded and became the capital of southern Epirus and Acarnania, with the right of sending five representatives to the amphictyonic council. On the spot where his tent had stood Octavian built a sanctuary to Neptune adorned with *rostra* (the beaks of captured galleys), and instituted the Actian games in honour of Apollo. The city was restored by the emperor Julian and again (after the Gothic invasion) by Justinian, but in the middle ages it was supplanted by Preveza.

NICOSIA, the capital of the Republic of Cyprus and seat of the archbishop of the autocephalous Church of Cyprus, lies on the Pedieos river about 500 ft. above sea level in the centre of the plain between the Kyrenia mountains and the Troodos massif. Pop. (1960) 45,490, with suburbs 95,343. It contains the presidential palace, the chamber of representatives, the Greek and Turkish communal chambers, the British high commission building and the foreign embassies. It is also the professional and educational centre of Cyprus. There are two chief thoroughfares: Kyrenia street continuing into Ledra street (north and south) and Hermes street continuing into Paphos street (east and west). Ledra street is the Greek business and shopping centre while the northern half of the walled town is largely Turkish. The fine Gothic cathedral of St. Sophia, dedicated in 1325, was converted by the Turks into the Selimiye mosque. The town has several public gardens, in one of which stands the municipal theatre. Near it is the Cyprus museum, erected in 1907 with later extensions.

Nicosia is connected by good roads with the port of Famagusta (38 mi.) and the other chief towns of the island. From Nicosia airport, 5 mi. from the city, there are daily flights direct to London and connecting services with New York and the principal airports in Europe and the middle east. There are many light industries, mainly serving the local market. Manufactures include cotton yarn and textiles, cigarettes, flour, soft drinks, confectionery, footwear and underwear.

The town was known in antiquity as Ledra, and under the Byzantines by the Greek name Lefkosia, corrupted by the Latins to Nicosia. A kingdom in the 7th century B.C. and a bishopric from the 4th century A.D., it has been the seat of government from the 10th century. The Lusignan kings walled the town, which covered a much larger area than that enclosed by the existing Venetian fortifications (3 mi. round). In 1373 it was sacked by the Genoese and in 1426 by the Mamelukes, when the royal palace (a fragment of which survives near the Paphos gate) was destroyed. Many of the Latin religious foundations were abandoned and the medieval city never fully recovered. Under the Venetians, who occupied Cyprus in 1489, the Greeks again had their cathedral (the ruined Bedestan beside St. Sophia). Work started on the new walls in 1567, but was incomplete when a large Turkish invasion force landed in 1570, and the town was again plundered. The Turkish governors established themselves in the former palace of the Lusignans, where the law courts now stand. When Cyprus came under British administration in 1878, Nicosia had greatly declined, but during the 20th century building was extended far beyond the Venetian walls and dry moat. Within these walls the old town has been largely rebuilt, with only a slight widening of its medieval streets. (A. H. S. M.)

NICOTIANA, a genus of plants of the nightshade family (Solanaceae), comprising about 60 species of usually sticky herbs and shrubs, native chiefly to tropical America. Besides *N. tabacum*, important as the source of commercial tobacco (*q.v.*), several other species are cultivated as ornamental plants. They are strongly scented annuals or perennials, possessing narcotic-poisonous properties. They have alternate, simple, usually entire but sometimes wavy-margined large leaves, and white, yellow, greenish or purple, very fragrant flowers, with a long, tubular, five-lobed corolla, usually opening at night.

About ten species are found in the southern and western parts of the U.S., and *N. glauca* (tree tobacco), a slender evergreen shrub native to Brazil, has become widely naturalized on the Pacific coast. *N. rustica,* one of the plants known as wild tobacco, formerly cultivated by the Indians of the eastern states, is of uncertain origin, but is almost certainly the source of the first tobacco taken from Florida to Lisbon and popularized by Jean Nicot, for whom the genus and nicotine were named. Beautiful night-fragrant species for the garden are *N. alata* var. *grandiflora* (jasmine tobacco), three to four feet high, and the somewhat shorter *N. sylvestris,* both tender perennials from South America.

Nicotianas, easily grown from seed and root cuttings, are sensitive to frost. They do well in light rich soil in a warm sheltered location and frequently self-sow in the garden; some make good potted plants.

See T. H. Goodspeed, "The Genus Nicotiana," in *Chronica Botanica*, vol. xvi (1954). (N. Ta.)

NICOTINE, a volatile liquid, is the principal alkaloid of tobacco (*q.v.*), in which it occurs to the extent of about 5% along with minute amounts of closely related alkaloids. Nicotine is used chiefly as a contact insecticide for plants and animals. It is prepared by adding lime or caustic soda to a filtered, concentrated, aqueous extract of tobacco (stalk and other tobacco refuse is generally used) and recovering the alkaloid by extraction with a suitable solvent or by steam distillation. This crude alkaloid is freed from water by a chemical drying agent, such as solid potash, and then fractionally distilled. Pure nicotine, $C_{10}H_{14}N_2$, is a highly poisonous, colourless liquid with an unpleasant odour; it boils at 246°–247° C. and is soluble in most solvents, including water. The dipicrate crystallizes in short, yellow prisms that melt at 224° C. and can be used in the identification of nicotine.

NICTHEROY: *see* NITERÓI.

NICUESA, DIEGO DE (*c.* 1465–1511), Spanish conqueror, was born at Baeza, Jaén. He accompanied Gov. Nicolás de Ovando to the West Indies in 1502 and was active in the early settlement and organization of Santo Domingo. In 1508 Nicuesa received a grant to conquer and govern a colony on the South American mainland called Veragua west of the Gulf of Darién and extending north to Cape Gracias a Dios in Panama (Honduras). At the same time, Alonso de Ojeda was awarded an adjoining grant to the east. In Nov. 1509 Nicuesa's expedition of 745 men left Santo Domingo in five ships. However, they soon encountered bad luck. The larger ships were lost on the inhospitable coast, and no settlement could be made because of attacks by the Indians until Nicuesa decided to "stop here in the name of God" at Cape "Gracias a Dios." There his forces were further reduced by hunger, Indian attacks and disease. Ojeda's men, by then left leaderless, found themselves within the limits of Nicuesa's grant and invited him to be their governor. But they heard of his overbearing conduct and bad reputation among his own men, and when he arrived in March 1511, they refused to let him land. He was forced out to sea in a leaking craft and perished with a number of faithful friends. (U. S. L.)

NIDWALDEN, a demi-canton of central Switzerland, which, with the demi-canton of Obwalden, forms the founder canton of Unterwalden (*q.v.*). Pop. (1960) 22,188. Stans, the capital (4,337), has a baroque church (1641–47) with a Roman tower, and a monument to Arnold von Winkelried, the hero of Sempach. Johann Heinrich Pestalozzi, the humanist educator, founded his first orphanage there in 1798. Nidwalden offers winter sports and its tourist resorts include the Bürgenstock mountain mass that projects into the Lake of Lucerne.

NIEBUHR, BARTHOLD GEORG (1776–1831), German historian who started a new era in historical studies by his method of source criticism; all subsequent historians are in some sense indebted to him. Niebuhr, the only son of the Danish explorer Carsten Niebuhr (*q.v.*), was born in Copenhagen on Aug. 27, 1776. Up to his matriculation at Kiel university he had a solitary education which perhaps intensified his leaning toward a life of scholarship. But on his father's advice he spent over a year in England and Scotland and then embarked on a career in state service, becoming private secretary to Count Schimmelmann, the Danish minister of finance, and in 1804 director of the national bank. In 1806, at the request of Baron von Stein, the Prussian chief minister, he took up a similar post in Prussia. Two years after Stein's fall (1808), however, disapproving of Prince von Hardenberg's

policy, he resigned and became state historiographer. At the same time he became a member of the Berlin Akademie der Wissenschaften and was thereby empowered to lecture at the newly founded university of Berlin. In 1810 he began the series of lectures on Roman history which were the basis of his great book and which made a sensation in Berlin. In 1816 he went as Prussian ambassador to the Vatican, retiring to Bonn in 1823 where he died on Jan. 2, 1831. Niebuhr's chief work was done while he was employed in public service. His interests were academic (to the fine arts he was wholly indifferent; it has been said that to him Rome was only a collection of unsolved problems) and he never wholly reconciled himself to his official career; yet he held that no one could understand the history of Rome without knowing the state as it is seen by the statesman; and his work, above all his gift for analogy, benefited greatly from his practical life.

Niebuhr's *Römische Geschichte* (3 vol., 1811–32; Eng. trans. 1828–42) marked an era in the study of its special subject and had a momentous influence on the general conception of history. Niebuhr made particular contributions of value to learning, *e.g.*, his study of social and agrarian problems; on the other hand some of his theories were extravagant and his conclusions mistaken. But his permanent contribution to scholarship was his method. The failings of classical sources were already recognized but it was Niebuhr who evolved what Goethe called *"tätige Skepsis"*—the constructive skepticism which is the root of a scientific method of criticism. It was Niebuhr who showed how to analyze the strata in a source, particularly poetical and mythical tradition; how to discard the worthless and thereby lay bare the material from which the historical facts could be reconstructed. He thus laid the foundation for the great period of German historical scholarship.

NIEBUHR, CARSTEN (1733–1815), German traveler who was the sole survivor of the first scientific expedition to Arabia and the compiler of its results, was born at Ludingworth, Hanover, on March 17, 1733. He worked as a peasant in his early years, but managed to learn surveying. In 1760 he was invited to join the expedition being sent out by Frederick V of Denmark for the scientific exploration of Egypt, Arabia and Syria. The expedition visited the Nile, Mount Sinai, Suez and Jidda, whence it journeyed overland to Mokha. In May 1763 the philologist of the expedition, F. C. von Haven, died, followed in July by the naturalist, Pehr Forskål. Sana, the capital of Yemen, was visited, but the remaining members of the expedition were obliged to return to Mokha. Niebuhr saved his life and restored his health by adopting native dress and food. From Mokha they sailed to Bombay, where the artist and the surgeon of the expedition died, leaving Niebuhr alone. He stayed 14 months in India and then turned homeward by way of Muscat, Persia, Mesopotamia, Cyprus and Asia Minor, reaching Istanbul via Brusa in Feb. 1767 and Copenhagen in the following November. He later held posts in the Danish military service and in the civil service of Holstein. He died at Meldorf in Holstein on April 26, 1815.

Niebuhr's major works are *Beschreibung von arabien* (Fr. trans., *Description de l'Arabie*) and *Reisebeschreibung nach arabien und andern umliegenden landern* (Eng. trans., *Travels Through Arabia*). He also edited P. Forskål's *Descriptiones animalium, Flora aegyptiaco-arabica* and *Icones rerum naturalium*.

See the anonymous *Life of Carsten Niebuhr* in the "Lives of Eminent Persons" series (1838); and D. G. Hogarth, *The Penetration of Arabia* (1904).

(Wm. C. B.)

NIEBUHR, REINHOLD (1892–), U.S. Protestant theologian and social critic, a pioneer in the "new theology" or Neo-orthodoxy (*q.v.*) that has striven to restate the biblical-Christian teaching in a form relevant to the great issues of contemporary life and history. Niebuhr's influence has been widespread, cutting across the lines of the diverse religious communities as well as of the various academic disciplines dealing with human affairs. The influence of his thinking has been felt alike in theology and in the fields of history, political science and international affairs.

Niebuhr was born on June 21, 1892, at Wright City, Mo., the son of a clergyman. He attended Elmhurst college (1910), Eden Theological seminary (1913) and Yale Divinity school (B.D., 1914; M.A., 1915). He received a D.D. from Eden Theological seminary in 1930 and numerous honorary degrees from institutions in the United States and abroad. He was ordained to the ministry of the Evangelical Synod of North America in 1915 and served as a pastor in Detroit from 1915 to 1928. In the latter year he joined the faculty of Union Theological seminary in New York city, serving as associate professor of the philosophy of religion until 1930 and as professor of applied Christianity until 1960, the year of his retirement. He married Ursula Keppel-Compton in 1931.

In his earliest writings, Niebuhr exhibited the quasi-humanistic religious "liberalism" and social idealism that pervaded the theological atmosphere of the time. Increasing experience with the actualities of social life which he encountered in the course of his ministry in a great industrial city, together with his reflections on world affairs, sharply reoriented his thinking in a direction more orthodox theologically and more realistic socially. *Moral Man and Immoral Society*, published in 1932, embodying this new orientation, came as a tract for the times, combining a somber Augustinian emphasis on the involutions of sinful self-love in the individual and corporate structures of life with a social radicalism bordering on Marxism. His Marxist inclinations vanished in the years after World War II, and he in fact became a vigorous critic not only of totalitarian communism but of doctrinaire socialism as well; the original combination of a hardheaded Augustinian doctrine of man with a lively social concern, however, remained characteristic of his thought.

The most impressive statement of his fundamental theological position Niebuhr developed in his Gifford lectures, published as *The Nature and Destiny of Man* (2 vol., 1941–43). This work is a sustained and systematic attempt to restate, assess and vindicate the essential Augustinian-Reformation teachings on man in the context of an "existentialist" understanding of the human situation, emphasizing at once man's dynamic of self-transcendence, the ambiguities of his creaturely existence and the corruptions of his sinful egocentricity. It was this work that brought Niebuhr closest to continental neo-orthodoxy, although he was throughout very critical of both Karl Barth and Emil Brunner.

In later years Niebuhr's thinking shifted more and more to a concern with the problem of history and an emphasis on man's essential historicity ("Man's being and human society are by nature historical. . ."). *Faith and History* (1949), *The Irony of American History* (1952) and *The Self and the Dramas of History* (1955) mark this new direction. The last-named work is particularly significant for what it owes to the "relational" (or "dialogical") philosophy of Martin Buber, an influence that came late but remained powerful in Niebuhr's thought. His *The Structure of Nations and Empires* (1959) combines this concern with history with his lifelong preoccupation with the problems of political power.

Bibliography.—Niebuhr's writings and his commentaries on religious, social and political affairs are voluminous. A full bibliography to 1956 may be found in Charles W. Kegley and Robert W. Bretall (eds.), *Reinhold Niebuhr: His Religious, Social, and Political Thought* (1956), and a collection of his outstanding occasional articles in D. B. Robertson (ed.), *Love and Justice: Selections From the Writings of Reinhold Niebuhr* (1957). Important studies of Niebuhr's thought include Edward J. Carnell, *The Theology of Reinhold Niebuhr* (1950); Georgette Paul Vignaux, *La Théologie de l'histoire chez Reinhold Niebuhr* (1957); Gordon Harland, *The Thought of Reinhold Niebuhr* (1960).

NIEDERSACHSEN: *see* Lower Saxony.

NIEL, ADOLPHE (1802–1869), French army officer, one of the emperor Napoleon III's marshals, was born at Brioudes, Haute-Garonne, on Oct. 4, 1802. Trained as an engineer, he was commissioned in the army in 1825; took part in three campaigns in Algeria (1837–39); superintended the fortification of the St. Denis region; and was promoted lieutenant colonel in 1842 and colonel in 1846. In 1849, as chief of staff to Gen. J. B. P. Vaillant in the papal states, he distinguished himself in the capture of Rome from the republicans. General of division in 1853, he

was twice on active service in command of the engineers during the Crimean War: during the expedition to the Aaland Islands and at the siege of Sevastopol. Aide-de-camp to Napoleon III from 1854 and a senator from 1857, he went to Turin to conclude the alliance of Jan. 1859 between France and Sardinia-Piedmont; in the ensuing war against Austria he played a decisive role in the battle of Solferino, for which he was made marshal next day (June 25, 1859). Appointed minister of war on Jan. 18, 1867, he planned a radical reorganization of the army, but met with obstruction and did not live long enough to put his valuable law of Feb. 1, 1868, into effect. Niel died in Paris on Aug. 13, 1869.

NIELLO: *see* Metalwork, Decorative: *Techniques of Metalworking.*

NIELSEN, CARL AUGUST (1865–1931), the outstanding Danish composer of his time. Born on June 9, 1865, at Norre Lyndelse, near Odense, he entered the conservatory of music at Copenhagen in 1884 where he studied with O. Rosenhoff and N. Gade. He was violinist in the court orchestra at Copenhagen intermittently from 1886 to 1905, conductor at the court theatre (1908–14) and director of the *Musikforeningen* (Music society) from 1915 to 1927. In 1915 he was appointed professor at the Copenhagen conservatory. Nielsen's early music was influenced by the romantic composers, but his later works were more enterprising and made use of polytonality. He became known for his six symphonies, particularly the second, *Die fire temperamente* (1902), the third, *Sinfonia espansiva* (1911), and the fourth, *Det uudslukkelige* ("The Inextinguishable," 1916), all of which are richly scored. He also wrote three concertos—for violin, for flute and for clarinet; the operas *Saul og David* (Copenhagen, 1902) and *Maskerade* (Copenhagen, 1906); four string quartets, two quintets, organ and piano music. His early *Hymnus amori* for soloists, chorus and orchestra reveals an influence of Palestrina. He died at Copenhagen on Oct. 3, 1931.

See R. Simpson, *Carl Nielsen* (1952); T. Meyer and F. S. Petersen, *Carl Nielsen*, 2 vol. (1947–48). (J. S. Wn.)

NIEMCEWICZ, JULIAN URSYN (1757?–1841), Polish man of letters who greatly enriched the intellectual life of his day, was born at Skoki, near Brzesc (Brest), on Feb. 6, 1757 or 1758, and educated in the Warsaw Cadet corps (1770–77). He spent the greater part of the period 1783–88 in western Europe. In 1788 he was elected deputy to the *sejm* (parliament). Having been Tadeusz Kosciuszko's aide-de-camp during the insurrection of 1794, he was captured at Maciejowice and imprisoned at St. Petersburg. After his release, late in 1796, he went to the United States, returning to Poland in 1807. In 1831 he went to England as emissary of the insurrectionary government. In 1833 he moved to Paris, where he died on May 21, 1841.

Niemcewicz's works include the most outstanding 18th-century Polish comedy (*Powrót posła*, 1790); a collection of songs on themes from Polish history (*Śpiewy historyczne*, 1816); and *Lejbe i Siora* (1821; Eng. trans., 1830), the first Polish novel to discuss the Jewish problem. His *Memoirs* (*Pamiętniki czasów moich*, 1848) were reprinted in 1957.

See J. Chrzanowski, "Pochwała Niemcewicza," *Roczniki Towarzystwa Naukowego Warszawskiego* (1927); J. Dihm, *Niemcewicz jako polityk i publicysta* (1928). (L. R. Lr.)

NIEMÖLLER, (FRIEDRICH GUSTAV EMIL) MARTIN (1892–), founder of the German Confessing Church (*q.v.*), was born on Jan. 1, 1892, in Lippstadt (Westphalia), the son of a pastor. After serving as a naval officer in World War I he studied theology at Münster and in 1931 became pastor in the fashionable Berlin suburb, Dahlem. In 1933, in protest against National Socialist interference in the church, he founded the *Pfarrernotbund* (Pastor's Emergency league), which, among other things, rejected discrimination against Jewish Christians. Niemöller became a leading member of the Confessing synod of the Evangelical Church. He preached throughout Germany and on March 1, 1938, the Gestapo arrested him, sent him to Sachsenhausen concentration camp and later to Dachau. In 1945, together with Léon Blum and others, he was removed to the Tirol and there was freed by the Allies.

In 1945 Niemöller became head of the German Evangelical Church's foreign relations office and in 1947 president of the church in Hesse-Nassau. The ecclesiastical restoration and the absence of any real change in the German mentality seriously disillusioned him. He opposed the remilitarization of Germany and in 1954 became a pacifist. Niemöller's strength lies in the simplicity of his Bible witness: it demands not just personal piety but active support for international reconciliation and social justice. As a leading German churchman he went to Moscow in 1952, and later lecture tours took him to every continent. In 1961 he was elected one of the six presidents of the World Council of Churches.

Bibliography.—M. Niemöller, *Vom U-Boot zur Kanzel* (1934); *Bekennende Kirche*, essays presented to Niemöller on his 60th birthday (1952); D. Schmidt, *Pastor Niemöller*, Eng. trans. (1959); C. Start-Davidson, *God's Man* (1959). (H. Ko.)

NIEN REBELLION, a major revolt in northern China during the 1850s and 1860s. When the T'ai P'ing armies in 1853 were pushing down the Yangtze river to capture Nanking (*see* T'ai P'ing Rebellion), an uprising broke out in the north China plain led by the Nien secret society, an offshoot of the White Lotus society. Scattered Nien bands, which had fomented sporadic revolts since the first decade of the 19th century, met at Chih-ho in the winter of 1852–53 to form a coalition under the leadership of Chang Lo-hsing and to establish a base of operation in the area north of the Huai Ho in Anhwei.

The northern expedition of the T'ai P'ings in the summer of 1853 gave the Nien the opportunity to consolidate their power. Two years later, the Nien forces, led by family elders, had grown so strong that they were reorganized into five banner armies. Numbering 30,000 to 50,000 they were a motley horde of peasants and army deserters, brigands and salt smugglers, accompanied by their wives and children. They won the support of the local force that had been organized to resist the T'ai P'ings and gained control over the network of mud walls and ditches built by the local troops. With their home base strongly bulwarked and with their cavalry force well organized, Nien columns raided Shantung and Kiangsu, Honan and Hupeh, while they fought alongside the T'ai P'ings in the south.

The loss of their citadel, Chih-ho, to the imperialists led by Seng-ko-lin-ch'in and the death of their leader, Chang Lo-hsing in the spring of 1863, were severe setbacks for the Nien. But their armies remained intact and they rallied to the leadership of Chang's nephew, Chang Tsung-yü. After Nanking fell to imperial forces in July 1864, the Nien were reinforced by a T'ai P'ing army under Lai Wen-kuang that had been operating in Shensi. Organized in military order, they became highly effective in mobile warfare specializing in hit-and-run tactics to elude or to harry the better armed imperialists. They struck at weak points to gain recruits and to obtain supplies but evaded frontal battles.

After the Nien defeated and killed Seng-ko-lin-ch'in in 1865, Tseng Kuo-fan, who took over command of the government forces adopted the strategy of blockade. But the Nien rebels slipped through his cordon and, in the winter of 1866, they split into two armies, the eastern under Lai Wen-kuang and the western under Chang Tsung-yü. After an incursion into Hupeh, the eastern Nien forces were trapped in Shantung by the Huai army under Li Hung-chang and destroyed in the beginning of 1868. The western Nien army, which had invaded Shensi with the aim of joining forces with the Muslims, hastened back. It threatened Peking but, in Aug. 1868, after 15 years of war in eight provinces, it was surrounded and annihilated.

See Siang-tseh Chiang, *The Nien Rebellion* (1954); Ssu-yü Teng *The Nien Army and Their Guerilla Warfare, 1851–1868* (1961). (Jc. L.)

NIETZSCHE, FRIEDRICH (1844–1900), German philosopher, one of the most influential thinkers of modern times, was born Oct. 15, 1844, at Röcken, in the Prussian province of Saxony, the son of a Lutheran minister and the grandson of two [illegible]. The religion of his home had a patriotic complexion, and he was named Friedrich Wilhelm after the reigning king of Prussia. Nietzsche later dropped the "Wilhelm," and no major writer has been a more

stringent critic of his countrymen or of the religion and morality of his fathers. In the English-speaking world his ideas have sometimes been discounted as a mere reaction against his childhood training, but in Germany and in France the most serious philosophers and psychologists, theologians, novelists and poets have unstintingly acknowledged their debt to him.

Basel and Bayreuth.—Nietzsche attended the universities of Bonn and Leipzig and in 1869 was appointed professor of classical philology at the University of Basel. He became a Swiss subject, but when the Franco-German War broke out in 1870, he requested a leave from his university to serve with the Prussian army as a medical orderly. Soon he returned to Basel, his health badly shattered. He offered courses in Greek literature and philosophy and found further inspiration in his friendship with the composer Richard Wagner, who was then living at Tribschen, near Lucerne.

Wagner was born in the same year as Nietzsche's father and appreciated Nietzsche as a brilliant apostle and errand boy. Nietzsche's first book, *The Birth of Tragedy From the Spirit of Music* (*Die Geburt der Tragödie aus dem Geiste der Musik*, 1872) won the composer's enthusiastic approval: the last ten sections were devoted to a rhapsody on Wagner. Of Nietzsche's four essays published as *Untimely Meditations* (*Unzeitgemässe Betrachtungen*, 1873–76), Wagner especially liked the last: "Richard Wagner in Bayreuth." Wherever Nietzsche showed an independent mind, Wagner showed little sympathy. A break was thus inevitable, and Wagner's removal to Bayreuth merely hastened it. The composer made his peace with the young German empire, which Nietzsche considered a cultural menace, and his ideas became influential. Wagner's chauvinism and anti-Semitism, which had mattered less when he was the lonely genius of Tribschen, were now institutionalized as part of the meaning of Bayreuth. Wagner's *Parsifal*, finally, seemed to Nietzsche a thoroughly insincere obeisance to Christianity, and the philosopher had no sympathy for Wagner's deliberate idealization of "pure foolishness." Wagner's inscribed copy of *Parsifal* reached Nietzsche even as Nietzsche's enlightened *Human, All-Too-Human* (*Menschliches, Allzumenschliches*, 1878), with a motto from Voltaire, reached Wagner; and this book was at least as distasteful to the composer, who did not bother to finish reading it, as the opera was to Nietzsche. Their break was sealed.

Later Life and Works.—In 1879 Nietzsche resigned from the university, pleading his ill-health. He devoted the next ten years solely to his writing, living very modestly and driving himself relentlessly. Every book represented a triumph over his half-blind eyes migraine headaches and manifold physical agonies. His major works belong to this period. They were written in utter solitude in various places in Switzerland and Italy (particularly the Engadine and the Riviera) and were ignored by the public until Georg Brandes (Georg Morris Cohen) began to lecture on Nietzsche at the University of Copenhagen in 1888. Ten years later, Nietzsche was world famous.

In Jan. 1889, however, Nietzsche suffered a mental and physical breakdown; and he remained insane until he died, at Weimar, on Aug. 25, 1900. His illness never was diagnosed conclusively, but was probably an atypical general paralysis. In that case there must have been a syphilitic infection, which is usually supposed to have taken place during his student days, although he may have infected himself while ministering to sick soldiers during the war. That he generally lived the life of an ascetic is agreed.

Although he proposed marriage to several women, Lou Salomé was the only one who, for a time, deeply moved his heart. His other proposals represented frantic attempts to escape from his desperate solitude. He scarcely knew the women in question and was profoundly relieved when they refused. Lou Salomé, who later wrote several books and became the beloved of Rainer Maria Rilke and, still later, a friend and disciple of Sigmund Freud, meant a great deal to Nietzsche in 1882—much more than he meant to her. To her, and only to her, he spoke of his inmost ideas; and when the intrigues of his envious sister, Elisabeth, disrupted their relationship, he felt lonelier than ever.

It was then that his most popular, most enigmatic and least understood work was born: *Thus Spoke Zarathustra* (*Also sprach Zarathustra*). After the aphoristic works of the preceding years, culminating in *The Dawn* (*Morgenröte*, 1881) and *The Gay Science* (*Die fröhliche Wissenschaft*, 1882), this was his first attempt to present the whole of his thought. The first three parts appeared in 1883 and 1884 but found no response, and Nietzsche abandoned the project after the fourth part, although it was at first intended as an intermezzo. After *Zarathustra*, Nietzsche composed *Beyond Good and Evil* (*Jenseits von Gut und Böse*, 1886) and *The Genealogy of Morals* (*Zur Genealogie der Moral*, 1887) in a less poetic vein, to clarify his ideas.

Nietzsche's Sister and Last Works.—The *femme fatale* both in Nietzsche's life and for his posthumous reputation was his sister. After his break with Wagner she showed no understanding and little sympathy for his development. She married an anti-Semitic agitator, Bernhard Förster, of whose activities Nietzsche unequivocally disapproved, and moved to Paraguay with her husband to found a colony, "Nueva Germania." After her husband's suicide in the midst of a major financial scandal, she tried to make a national hero of him while salvaging the colony as an island of Teutonic Christianity. Having failed in both attempts, she secured the rights to her brother's literary remains and edited them without scruple or understanding. In an early manuscript, for example, in which Nietzsche mentioned that their father had suddenly become mentally ill and died soon after (in 1849), she erased a few words and published the text as saying that he had become ill after a fall down the cellar stairs. She secured letters which her brother had written to others and suppressed some of them, while publishing his drafts for many of them as drafts for letters to herself, occasionally even erasing address and signature in the notebook manuscripts.

While she gained a wide audience for her misinterpretations, she withheld her brother's self-interpretation, *Ecce Homo*, until 1908. Meanwhile she collected some of his notes under the title *The Will to Power* (*Der Wille zur Macht*) and presented this work, first as part of her three-volume biography (Leipzig, 1895–1904), then in a one-volume edition (1901) and finally in a completely remodeled two-volume edition (1906). Ever since, the two-volume edition has been widely considered Nietzsche's crowning systematic labour. In fact, he had long used many of these notes in writing his later works, where they are occasionally given unexpected twists, while other notes had not been used by him because they were mere jottings and not acceptable formulations of his views. His later books, moreover, became less and less aphoristic and more and more continuous. Clearly, his projected main work, which he planned for a time to call *The Will to Power*, would have looked completely different even in form from the book that his sister put forward.

In 1888, after he had dashed off *The Wagner Case* (*Der Fall Wagner*), a brief polemic, he abandoned the former title and decided to call his main work *Revaluation of All Values* (*Umwertung aller Werte*). He finished the first part, an essay of about 100 pages, and called it *The Antichrist* (*Der Antichrist*, 1888). It is here and in *Twilight of the Idols* (*Götzen-Dämmerung, oder Wie man mit dem Hammer philosophirt*), written earlier in 1888, and in *Ecce Homo*, written in the autumn of that year, that we encounter Nietzsche's final views, not in the sister's book which, however, contains many highly interesting notes. His last literary labour was to assemble under the title *Nietzsche contra Wagner* some passages from his earlier books, slightly revised here and there. This is his shortest and perhaps most beautiful book.

Those who have looked to *The Will to Power* as Nietzsche's magnum opus have found him all but incoherent. In any case, his memorable formulations have invited quotation out of context and prompted a great variety of untenable and mutually contradictory interpretations, beginning with those of his sister. It was at her repeated request, furthermore, that Adolf Hitler eventually consented to visit her Nietzsche-Archiv in Weimar, on his way to Bayreuth. Nietzsche had once written to her that it was typical of her to try to reconcile opposites, and this is epitomized in the name that she adopted after her husband's suicide: Förster-Nietzsche. Although the Nazis followed her lead and published some misleading anthologies of Nietzsche's thought, they could

draw little comfort from his unexpurgated works. All serious students of the matter are agreed that the Nazi version of Nietzsche represents an utterly unscrupulous perversion of his thought.

Will to Power and Overman.—In the course of his psychological observations, Nietzsche gradually came to the conclusion that all human behaviour could be reduced to a single basic drive, the will to power. This notion is inseparable from his idea of sublimation, and the will to power is first discussed at any length in the chapter "On Self-Overcoming" in *Zarathustra*.

What man and every living being wants more than anything else is, according to Nietzsche, a higher, more powerful state of being in which the thousandfold impotence of his present state is overcome. Man wants to perfect himself, to re-create himself, to become a creator rather than a mere creature. It is only when he fails in this endeavour and resigns himself more or less to this failure that he seeks crude power over others as a substitute. Power is wanted in any case, but "power" in the vulgar sense is wanted only for lack of something better.

The higher state for which man strives, Nietzsche calls the overman (*Übermensch*). The overman is the man who has overcome himself; the passionate man who is the master of his passions; the creator who excels in both passion and reason and is able to employ his powers creatively. Although Nietzsche once remarks in *Zarathustra* that there has never yet been an overman, he says in *The Antichrist* (sec. 4): "Success in individual cases is constantly encountered in the most widely different places and cultures: here we really do find a *higher type*, which is, in relation to mankind as a whole, a kind of overman."[1] The disagreement between the two passages is not profound: it is only a question of either stressing the success of a Leonardo or of a Goethe, or emphasizing that even they were in some respects all too human.

The Last Man.—The overman serves Nietzsche as a contrast to man as he is, to "the last man" and to God. The last man appears in "Zarathustra's Prologue" where it is suggested—and this is confirmed elsewhere, most incisively and vitriolically in *Ecce Homo*—that evolution, biological or social, will lead not to the attainment of the overman but in the direction of the last man, who is an uncreative conformist and a complacent hedonist. "One still loves one's neighbor and rubs against him, for one needs warmth . . . A little poison now and then: that makes for agreeable dreams. And much poison in the end for an agreeable death. One still works, for work is a form of entertainment. But one is careful lest the entertainment be too harrowing. One no longer becomes poor or rich: both require too much exertion. Who still wants to rule? Who obey? Both require too much exertion. No shepherd and one herd! Everybody wants the same, everybody is the same: whoever feels different goes voluntarily into a madhouse."

The contrast between the overman and the last man epitomizes Nietzsche's critique of modern civilization. This critique is worked out in great detail and includes not only a critique of the pleasure principle, both as a norm and as the basis of any psychological monism, but also, and above all, a critique of the Christian religion and of morality.

God and the Eternal Recurrence.—The contrast of overman and God is also formulated in "Zarathustra's Prologue": "Remain faithful to the earth, and do not believe those who speak to you of otherworldly hopes!" Perfection can be hypostatized as existing even now in another world, in God, or it can be presented as a challenge and ideal for every one of us. Instead of resigning ourselves to being all too human and worshipping perfection, we can try to perfect ourselves in this life, on this earth.

The image of eternity is, for Nietzsche, the circle. He believed in the eternal recurrence of the same events at gigantic intervals. This he considered the most scientific of all hypotheses. Granted a finite number of power quanta as the basic constituents of the world, only a finite number of configurations would be possible. Now if we do not cling to the Christian belief in creation, there is no beginning of the past, nor has a stable end state been attained by now. The only alternative, Nietzsche supposes, is that the configurations must repeat themselves after enormous periods of time. "And this slow spider, which crawls in the moonlight, and this moonlight itself, and I and you in the gateway . . . must not all of us have been there before? And return . . . must we not eternally return?"

This idea reverts to Stoic speculations. The world is not governed by a purpose; it is an eternally repeated senseless play, and we are condemned to play the same role over and over again. The overman, however, unlike Goethe's Faust, can say to every single moment: abide, thou art so fair—and if this is impossible, at least return eternally!

This conception of the overman does not entail faith in progress, which Nietzsche derided as "merely a modern idea, that is, a false idea" (in a discussion of the overman, *Antichrist*, sec. 4). For Nietzsche, overman and eternal recurrence belonged together. The idea of the overman is a challenge, not a prediction: it is an antithesis to God, even as the eternal recurrence of the same events is an antithesis to the Christian conception of time and history.

Critique of Christianity.—Nietzsche's opposition to Christianity is not confined to its otherworldliness which he considered a mere symptom. Otherworldliness is motivated by the will to power of the weak who have despaired of fulfillment in this life. They slander this world in favour of another world in which they hope for such power that "we shall judge angels" (I Cor. vi, 2, cited in *Antichrist*, sec. 45).

Christianity, according to Nietzsche, is born of weakness and breeds weakness, while making war on those who are better favoured. It is the revolt of failures of every kind: of slaves against masters, of unfree minds against freethinkers, of the mediocre against the exception. Christianity, he says, "has waged deadly war against this higher type of man"; "Christianity has sided with all that is weak and base, with all failures"; "it has corrupted the reason even of those strongest in spirit by teaching men to consider the supreme values of the spirit as something sinful, as something that leads into error—as temptations. The most pitiful example: the corruption of Pascal, who believed in the corruption of his reason through original sin when it had in fact been corrupted only by his Christianity." (*Antichrist*, sec. 5.)

Dionysus.—Although Nietzsche diagnoses any celebration of the "pure spirit" at the expense of the body as a slander against life, prompted by what he calls *ressentiment* (resentment), he does not extol the body at the expense of the spirit. Against licentiousness, which is lack of self-control, and against renunciation, whether prompted by a lack of passion or by fear of any kind, he pits his image of Goethe "who might dare to afford the whole range and wealth of being natural, being strong enough for such freedom; the man of tolerance, not from weakness but from strength, because he knows how to use to his advantage even that from which the average nature would perish; the man for whom there is no longer anything that is forbidden—unless it be *weakness*, whether it be called vice or virtue."

All of Nietzsche's heroes were, like Goethe, men of surpassing intelligence, not irrationalists and least of all "pure fools." With the exception of Arthur Schopenhauer, whom Nietzsche greatly admired in his youth but later criticized, they affirmed this world. To cite the continuation of his portrait of Goethe from *Twilight of the Idols:* "Such a spirit who has become free stands amid the cosmos with a joyous and trusting fatalism . . . *he does not negate any more*. Such a faith, however, is the highest of all possible faiths: I have baptized it with the name of *Dionysus*."

The "Dionysian" in Nietzsche's early works was contrasted with the "Apollinian": it represented the flood of passion as opposed to the serenity which found expression in Greek sculpture. In his later work, as in the quotation above, it represents passion controlled and creatively employed as opposed to the negation of the passions, of the body and of this world.

"Dionysus versus 'the Crucified One': there you have the contrast. It is not martyrdom that constitutes the difference—only here it has two different senses . . . The tragic man affirms even the harshest suffering: he is sufficiently strong, rich, deifying for this; the Christian negates even the happiest life on earth: he is sufficiently weak, poor, and disinherited to suffer from life in any

[1]All quotations are from *The Portable Nietzsche*, The Viking Press, 1954.

form. The God on the cross is a curse on life, a pointer to seek redemption from it; Dionysus cut to pieces is a *promise* of life: it is eternally reborn and comes back from destruction" (*The Will to Power*, note 1,052; written in 1888).

All of Nietzsche's many other criticisms of Christianity are corollaries of the major points here stated; *e.g.*, that most unevangelical sentiments of resentment have been central in Christianity from the beginning, even in the New Testament (though Nietzsche excepts Jesus from this charge); that the religion of Paul and of Catholicism, of Luther and of Calvin is a religion of vengefulness, judgment and negation; that Christianity is deeply antirational and antiscientific; that "the philology of Christianity" as exemplified in its treatment of the Old Testament is profoundly dishonest; that faith in the Christian sense involves self-deception. At bottom the charge is always the same: Christianity is born of weakness, failure and resentment and is the enemy of reason and honesty, of the body and of sex in particular, and of power, joy and freedom.

Slogans.—When Nietzsche took *How One Philosophizes With a Hammer* as the subtitle of *Twilight of the Idols*, he explained in his preface that his intention was "the sounding out of idols . . . which are here touched with a hammer as with a tuning-fork." He wanted "to pose questions here with a *hammer*, and, perhaps, to hear as a reply that famous hollow sound." Yet it has been widely assumed that his "hammer" was a sledgehammer. The slogan is recalled, the text forgotten.

When Nietzsche contrasted "master morality" and "slave morality" it was assumed that he identified himself with the former. In fact, he tried to show the need for "a *typology* of morals" to replace the prejudice that one's own morality is simply "morality." His cutting analysis of "slave morality" with its central *Ressentiment* is particularly pointed and original; but in the chapter on "The 'Improvers' of Mankind" in *Twilight of the Idols* he leaves no doubt of his distaste for master morality. He did not believe in the possibility of any universal moral code. Every morality was to him a prescription for living with one's passions, and different people require different prescriptions. A Luther cannot live like a St. Francis, and a St. Francis cannot live like Goethe. "One thing is needful" is the title of a long aphorism in *The Gay Science* which begins, "'Giving style' to one's character"; and it ends: "For one thing is needful: that a human being attain his satisfaction with himself . . . Whoever is dissatisfied with himself is always ready to revenge himself therefor; we others will be his victims."

That Nietzsche called himself a good European is often forgotten; that he called himself an immoralist is recalled. What he meant was not that he favoured a lack of discipline and letting oneself go. On the contrary, he insisted that without long and hard discipline we should lack all those achievements "for whose sake life on earth is worthwhile; for example, virtue, art, music, dance, reason, spirituality." His "immoralism" was in the main an impassioned nonconformism, and his choice of word was suggested by the fact that "morality" generally designates a social code that equates being moral with conforming.

Influence.—Of those hundreds who have written about Nietzsche, some authors quite deliberately perverted his meaning; others read their own ideas into their subject more or less unconsciously; and the vast majority had never read most of his books from beginning to end. The number of irresponsible interpretations is appalling. On the other hand he also exerted a commanding influence, in various ways, on some of the foremost writers of the 20th century: on Thomas Mann and Hermann Hesse, on Stefan George and Christian Morgenstern, on Rainer Maria Rilke and André Gide, on Karl Jaspers and Martin Heidegger, on Sigmund Freud and Bernard Shaw, on Oswald Spengler and Max Scheler, on André Malraux and Jean Paul Sartre. Freud often expressed his admiration for the profundity of Nietzsche's penetrating self-knowledge and for his insight into psychology. Spengler acknowledged in the preface to *The Decline of the West* that he owed "everything" to Goethe and to Nietzsche. According to Jaspers, Nietzsche belongs with Sören Kierkegaard. Together they determine the situation in which contemporary philosophy must begin. Heidegger sees Nietzsche as the last great metaphysician and the end point of a development begun with Plato. Thomas Mann fashioned the hero of his *Doktor Faustus* after Nietzsche; Malraux included an incident from his biography in *La lutte avec l'ange;* Albert Camus, like Thomas Mann and Stefan Zweig, wrote an essay on Nietzsche; and Stefan George, two poems. More than half a century after his death, his life and work had lost none of their fascination, and modern philosophy had not yet digested all he had to offer. For a portrait of Nietzsche *see* article GERMAN LITERATURE.

BIBLIOGRAPHY.—For a comprehensive bibliography, which lists the various editions of Nietzsche's works and letters as well as items not included in any collected edition and the most important works about him, *see* Walter Kaufmann, *Nietzsche: Philosopher, Psychologist, Antichrist* (1950), the revised ed. (1956) omits the long bibliography.

Of the many editions of Nietzsche's works in German the *Musarion-Ausgabe*, 23 vol. (1920–29), is the most complete. For an English text see *The Portable Nietzsche*, ed. and trans. by Walter Kaufmann (1954), containing *Thus Spoke Zarathustra, Twilight of the Idols, The Antichrist* and *Nietzsche contra Wagner*, as well as selections from his other books, from his notes and from his letters in chronological sequence. For studies *see* Charles Andler, *Nietzsche: sa vie et sa pensée*, 6 vol. (1920–31); Erich Podach, *Nietzsches Zusammenbruch* (1930), *Gestalten um Nietzsche* (1932); Karl Jaspers, *Nietzsche: Einführung in das Verständnis seines Philosophierens* (1936); George A. Morgan, Jr., *What Nietzsche Means* (1941); Martin Heidegger, "Nietzsches Wort 'Gott ist tot'" in *Holzwege* (1950). (W. KN.)

NIEUWPOORT (Fr. NIEUPORT), a town of the province of West Flanders, Belgium, lies near the mouth of the Yser river, 15 km. (10 mi.) S.S.W. of Ostend. Pop. (1961) 6,899. Parts of an ancient cloth market built in 1480 remained after World War I when the town was practically leveled; it was later rebuilt on a grid plan with replicas of many old buildings. Nieuwpoort has one of the main artificial drainage outlets of the low country. The six combined lock bridges of Palingbrug played an important part in World War I; they were the instruments of the famous flooding of the Yser front on Oct. 29, 1914, when the normal process was reversed and the sea water allowed to flow and remain inland, checking the German advance. Buses connect Nieuwpoort with the railway at Diksmuide. Sea fishing, canneries and chemical plants are now important occupations, but the main industry is tourism, especially at the suburb of Nieuwpoort-Bad, a fashionable North sea resort dating from 1869.

The mouth of the Yser was once east of Lombartzyde (Lombardsijde). When it silted up in 1116 ships went farther south to Sandeshove on another estuary, and the place became the *novus portus* ("new port"), whence Nieuwpoort. In the 13th century the town was rich like many Flanders towns. It was the port of Ypres and had shipyards and fish-curing installations. Strongly fortified, it withstood a siege by 20,000 French in 1489. Under its walls, in 1600, Maurice of Nassau defeated the archduke Albert and the Spaniards. (R. M. AN.)

NIÈVRE, a *département* of central France, was formed in 1790 from the ancient province of Nivernais (*q.v.*) together with a small part of Orléanais. It is surrounded by the *départements* of Yonne to the north, Côte d'Or and Saône-et-Loire to the east, Allier to the south, Cher to the west and Loiret to the northwest. Area, 2,640 sq.mi. Pop. (1962) 245,921. In the east are the granite highlands of the Morvan rising to rounded summits above 2,500 ft. (Mt. Prénelay, 2,805 ft.). They are flanked to north and west by clay vales (Bazois) and limestone hills (Côtes de Nivernais). In the west the land falls to the valley of the Loire river, but only a small area lies below 1,000 ft. The Loire crosses the southwest corner of Nièvre, and below Nevers forms its western boundary. Much of the centre and east lies within the upper basin of the Yonne tributary of the Seine.

The Morvan is a thinly peopled area of pastoral farming and woodcutting. The cattle reared there are fattened on the lush pastures of Bazois. The Lias clays of this district provide material for an old-established pottery industry. Farther west in Bas Nivernais wheat, potatoes and fodder crops are extensively grown. The vine is cultivated on favourable exposures of the limestone hills and in the Loire valley, where the white wine of Pouilly is of high repute. The Nivernais is a well-known heavy breed of horse. Iron ore contained in the Jurassic rocks was formerly widely worked and smelted with charcoal. Near Nevers at Imphy

and Fourchambault there are metallurgical industries. A small coalfield is worked near Décize, served by the Nivernais canal (1852), which connects the Yonne with the lateral canal that follows the Loire. Décize has glass and faïence works.

Nevers (*q.v.*), former capital of the duchy of Nivernais, situated at the confluence of the Nièvre with the Loire, is the largest town and *préfecture* of the *département*, as well as the seat of the bishopric. Besides the Gothic cathedral of St. Cyr, the Romanesque church of St. Etienne is noteworthy. In the museum that occupies the old episcopal palace is a fine collection of Nevers and other pottery. The law courts occupy the ducal palace of the 15th and 16th centuries. Farther down the Loire valley, the Benedictine abbey church of Ste. Croix at La Charité is a fine example of Burgundian Romanesque architecture. Pougues-les-Eaux is a small spa 7 mi. N. of Nevers, and there are other mineral springs at St. Aré near Décize and St. Honoré near Château-Chinon.

The *département* consists of four *arrondissements* centred upon the market towns of Nevers, Cosne, Château-Chinon and Clamecy. Its court of appeal is at Bourges and it comes under the *académie* of Dijon. (AR. E. S.)

NIFO, AGOSTINO (Lat. AUGUSTINUS NIPHUS or NYPHUS) (*c.* 1473–1538 [1545 or 1546?]), Italian philosopher who combined a mitigated Averroism with more worldly interests that won him the favour of the humanist princes of his time, was born either at Sessa in Campania or perhaps at Jopoli in Calabria. As professor of philosophy at Padua, he published a corrected version of his treatise *De intellectu et daemonibus* (1492; on the Averroist theme of the unity of all human intellects), which in its original manuscript form would have incurred a charge of heresy. He also edited the works of Averroës (1495–97). Subsequently he taught at Salerno (under the patronage of the prince Roberto Sanseverino), at Pisa, at Bologna and in Rome. Commissioned by Pope Leo X to refute the Alexandrism of Pietro Pomponazzi (*q.v.*), he defended the Catholic interpretation of Aristotle's doctrine on the soul in a treatise *De immortalitate animae contra Pomponatium* (1518). His other works include treatises on the infinity of the prime mover (*De infinitate primi motoris*, 1504), on government (*De regnandi peritia*, 1523; influenced by Machiavelli) and on beauty and love (*De pulchro et amore*, 1531). He is thought to have died at Salerno, in 1538 or in 1545 or 1546. There are collected editions of his minor works on moral and political subjects, 2 volumes (1645), and of his commentaries on Aristotle, 14 volumes (1654).

NIGDE (Arab. NAKIDAH), chief town of an *il* (province) of the same name in southern Turkey, is situated on the Kayseri-Cilician Gates (Kulek Bogazi) road, 75 mi. N.N.W. of Adana. Pop. (1960) 18,042. The town is remarkable for its buildings, many of which date from the Seljuk era. These include several fine mosques—Hanum, Rahmaniye, Ala et Tin, Songur Bey, Dis—and the mausoleum Hudavent Turbesi. After the fall of the Rum sultanate, of which it had been one of the principal cities, Nigde became independent and (according to Ibn Batutah, the Muslim traveler) ruinous and did not pass into Ottoman hands till the time of Mohammed II. It represents no classical town but, with Bor, has inherited the importance of Tyana, whose site lies about 10 mi. S.W. A Hittite-inscribed monument, brought perhaps from Tyana, has been found at Nigde. The town is linked by rail and road with the principal centres of Turkey.

NIGDE IL (pop. [1960] 322,917) forms a part of the central Anatolian plateau. It is semiarid steppe country, bounded in the south by the lofty Taurus mountains (Toros Daglari) and northwest by the massive volcanic Melendiz mountains. In winter the temperature is usually below freezing, whereas the summer is hot. Soils are fertile when irrigated, the chief crops being potatoes, onions, rye, apples and raisins. (N. TU.; E. TU.; S. ER.)

NIGEL (d. 1169), bishop of Ely, treasurer and effective chief of the exchequer under Henry I and Henry II, was nephew of Roger, bishop of Salisbury, Henry I's justiciar, who largely created the 12th-century exchequer. Educated by Anselm of Laon, in royal service by 1126 and treasurer by 1127, Nigel became bishop of Ely in 1133. In 1139 he was involved in the fall of Bishop Roger, when he and his kinsmen were accused by the Beaumont faction of treason. Nigel joined Matilda at Gloucester, but in 1142 was reconciled to Stephen and restored to his see. In 1154 Henry II brought him back to the treasury to restore the proper working of the exchequer, and the highly efficient Angevin financial machine was his monument. His son Richard FitzNeale succeeded him as treasurer and described the exchequer system in *Dialogus de Scaccario* ("Dialogue of the Exchequer," *c.* 1179). Incapacitated by paralysis, Nigel retired in 1164 or 1165 and died on May 30, 1169.

See F. Liebermann, *Einleitung in den Dialogus de Scaccario* (1875); R. L. Poole, *The Exchequer in the Twelfth Century* (1912). (G. W. S. B.)

NIGER, PESCENNIUS (GAIUS PESCENNIUS NIGER JUSTUS), rival Roman emperor A.D. 193–194, was an Italian, an equestrian army officer, promoted to the senate about 180. His earlier service had largely been in the eastern provinces, but in 185–186 he commanded an expeditionary force against deserters who had seized control of a number of cities in southern Gaul. Consul about 189, he was appointed legate of Syria, as a commander most popular in the east and among the urban populace of Rome, in the troubles at the end of Commodus' reign. When Commodus' successor Pertinax was murdered in the spring of 193, Niger was proclaimed emperor and accepted in all the Asiatic provinces. Septimius Severus, however, proclaimed by the legions of the Danube, marched east and speedily defeated him in the decisive battle of Issus in the autumn of 194. Niger fled, but was overtaken and killed. (JN. R. M.)

NIGER, REPUBLIC OF THE (RÉPUBLIQUE DU NIGER), a country of west Africa, bounded on the north by Libya, on the east by Chad, on the south by Nigeria and Dahomey, on the west by Upper Volta and Mali and on the northwest by Algeria. A former territory of French West Africa, the Niger gained its independence in 1960. Area 489,206 sq.mi. Pop. (1959) 2,556,211. Capital Niamey (*q.v.*).

Physical Features.—The Niger is a transitional region between savanna and desert, between the countries of the sedentary Negro peoples and that of the non-Negro nomads. Only 8% of the country receives more than 21 in. of rainfall annually, and 48% receives less than 4 in.

The countryside is monotonous, the main variations deriving from vegetation and climate. To the south, where rainfall is more than 20 in. annually, near the Nigerian frontier, the reclaimed savanna yields coarse millet and peanuts. But this is only a narrow strip, and the savanna gives way toward the north to a fairly varied Sahelian zone (the Sahel). The broad valley of the Niger river which runs through the southwestern part of the country lies in a crystalline base. But the base disappears on the east bank in a sill between the basins of the Niger and the Chad, under sandstone of various ages, sometimes very broken, sometimes, to the east, forming a plateau or plains which slope toward Lake Chad.

A MAP OF THE REPUBLIC OF THE NIGER SHOWING THE MAIN PHYSICAL FEATURES, PRINCIPAL TOWNS AND COMMUNICATIONS

where the rainfall is more than 12 in., the vegetation of thorn trees (acacias) is still quite dense and cultivation of small millet is possible.

Fairly rapidly, toward the north, the Sahara area is reached, and this is more complex. A heavy crystalline mountain mass, the Aïr massif, which is dominated by Pre-Cambrian gneisses and granites, with some Quaternary black volcanic lavas, tuffs and ashes, is pierced by deep valleys, the "Koris," where there is a dense vegetation of acacias and doum palms. The Aïr isolates a few basins: to the southwest, the Azaouack, with pasturage, from which valleys, now dry, run down to the Niger; farther east, the Ténéré, a sandy and particularly arid desert, broken by some relief. Some oases may be found, aligned from Bilma, in the Kaouar, to Djado. (J. D.)

People.—Alongside the sedentary Negro peoples—Djerma-Songhai on the Niger in the southwest, Hausa in the centre and south, Beriberi-Manga in the east—there exist the nomadic herdsmen—Fulani in the south, Berber Tuareg in the north, Teda and Daza, branches of the Tebu (*q.v.*) or Tubu, in the east. The Tuareg and Tebu live only in the desert. The Hausa constitute more than a third of the population. All these peoples are Muslim, though there are some pagan survivals.

History.—Acheulean carved stones have been found in the Bilma region, and Neolithic deposits are numerous in the Sahara area, which the Tuareg have doubtless occupied since a remote age. They established themselves in the Aïr massif in about the 11th century, and the Tuareg sultanate of Agadès dates at least from the 15th. The Djerma (or Zerma), who speaks Songhai (Sonrhai), seem to have arrived in the 17th century. The Hausa, who probably came from the northeast, formed from the 14th century onward a number of kingdoms, of which one, Gobir (Gober), expanded greatly in the 18th century and repulsed the Tuareg. Hausa cities also replaced Bornu as important entrepôts in the trade between north Africa and the central Sudan.

The Fulani had for long been infiltrating into Hausa land. One of them, Usman dan Fodio, in 1804 proclaimed himself commander of the faithful and preached the *jihad* ("holy war") against the Hausa, who tended to be lax in their religious observances. He defeated them and established in the former Hausa states the empire of Sokoto but failed in his attack on Bornu. (*See* also BORNU; FULANI; HAUSA; KANEM; SOKOTO.) These native movements then began to come into conflict with the French and English.

Frederick Hornemann, Mungo Park (*qq.v.*) and other European travelers explored the region in the late 18th–19th centuries. By an agreement of 1890 the English and French divided the country among themselves, following a line from Say on the Niger to Barroua on Lake Chad, a frontier precisely defined in 1899 and 1904. The French "military territory of the Niger" was created, the Tuareg were conquered and in 1904 Agadès was occupied.

The territory was at first dependent upon the Sudan. In 1922 it became a colony of the federation of French West Africa (*q.v.*). The capital, at first at Zinder, was transferred in 1926 to Niamey. The Niger became an overseas territory in 1946 and was granted a territorial assembly and then, in 1957, an elected government. In 1958, despite the local government, 72% of the electorate voted for membership in the French community. On Aug. 3, 1960, independence was proclaimed, and on Nov. 11 Hamani Diori was elected president. On Sept. 20 the Niger became a member of the United Nations. It is also a member of the Sahel-Bénin entente, with Ivory Coast, Upper Volta and Dahomey.

In 1964 an armed revolt by political exiles was crushed and several of its leaders executed. At national elections in Sept. 1965 President Diori, the only candidate, was reelected; the president had survived an assassination attempt in April by, it was said, the clandestine Sawaba movement. Relations with Dahomey were strained in the early 1960s, mainly because of boundary disagreements; the argument was settled, however, in 1966. (HU. DE.)

Population, Administration and Social Conditions.—The constitution of the Niger, adopted on Feb. 25, 1959, declares the country to be a democratic and secular state. Legislative power is vested in the national assembly, composed of 60 members elected for five-year terms by universal suffrage. The president, who is the head of state, is the chief executive officer, invested by the national assembly after each general election. The country is administered by a council of ministers nominated by the president.

For administrative purposes, the Niger is divided into 16 *cercles* or administrative divisions (Niamey, Agadès, Birni N'Konni, Dogondoutchi, Dosso, Filingué, Gouré, Madaoua, Magaria, Maradi, N'Guigmi, Tahoua, Téra, Tessaoua, Tillaberi, Zinder) and a number of subdivisons. The capital, Niamey, and Zinder are independent municipalities. The population is sparse (seven persons per square mile) and largely rural. Niamey is the largest town (pop. [1959] 30,030), and only three other towns have more than 10,000 inhabitants: Zinder (14,891), Maradi (11,762) and Tahoua (11,629). These towns and all the others of any size are in the south. Agadès (4,531) is the only sizable community in the north.

In 1945 the rate of school enrollment was only 1% of children of school age. This had risen to about 6% in 1960 and by the second half of that decade more than 50,000 pupils were attending primary schools; more than 2,500 were attending secondary schools; and more than 100 were in technical schools.

The Economy.—The resources of the Niger are crops and livestock, from which 94% of the population derives its livelihood. The Tuareg and the Fulani are stockbreeders. The Tuareg raise camels; the others raise smaller livestock and cattle. Livestock raising has been helped by the sinking of wells. Stock supplies an important trade on the hoof to Nigeria, meat to the Ivory Coast and Dahomey, refrigerated meat to Niamey and skins (chiefly goatskins). Quality of the stock, however, is impaired by the necessity for constant movement in search of water and by endemic disease. Further, the Fulani are reluctant to sell their cattle.

The Sahel, while it attracts stockbreeders, also attracts cultivators in increasing numbers, less in the west, where the country is less thickly populated, than in the centre. The Hausa have developed the cultivation of peanuts which, with cotton growing, has extended to such a degree that production of foodstuffs is no longer adequate. This is the reason for the agricultural colonization of the Sahel, where a growing number of villages are cultivating small millet. Rice is grown in the valley of the Niger. There is some tin and tungsten mining in the Aïr.

Peanuts are by far the country's most important export product, and a number of oil mills have been established. But the Niger suffers from its isolation and distance from the coast. It has no railway, and the Niger river is barely usable. The road system has been improved, however, and the road from Maradi to Dosso extended to Parakou in Dahomey, terminus of the railroad from Cotonou on the coast. A ferry at Niamey links with the road to Upper Volta. A bridge was constructed across the Niger at Gaya in 1958. There are airports at Niamey, Zinder and Agadès.

Radio Niger broadcasts from Niamey in French, Hausa and Djerma and is government controlled.

On May 12, 1959, the Niger signed a convention of co-operation with the Common Organization for the Saharan Regions (O.C.R.S.), providing for financial and technical assistance. It joined the West African Monetary union (established May 1962) and thus remained in the franc area. (J. D.)

NIGERIA (FEDERAL REPUBLIC OF NIGERIA), a country of west Africa, occupying the basins of the Niger and Benue rivers and extensive adjacent territories. Pop. (1963) 55,670,052. Area 356,669 sq.mi. Nigeria consists of four regions (known officially as Northern Nigeria, Eastern Nigeria, Western Nigeria and Mid-West Nigeria) and the federal territory of Lagos. The republic is a member of the Commonwealth of Nations. It extends northward from the elbow of the Gulf of Guinea between latitude 4° and 14° N. and is bounded west by the Republic of Dahomey, north by the Republic of the Niger and east by the republics of Chad and Cameroon.

This article contains the following sections and subsections:

I. PHYSICAL GEOGRAPHY

1. Geology and Structure.—Crystalline rocks of Pre-Cambrian age (Basement complex) comprise the larger part of surface exposures. These rocks make up the Jos plateau, the central areas of the northern plateau and the part of the southern hill belt lying west of the Niger. The characteristic hill forms are inselbergs and *kopjes* of bare rock, found most often immediately below each step in the landscape. Basement rocks also form much of the eastern highlands (especially in the northern districts) and of the plains immediately to the west.

The oldest sedimentaries are of Lower Cretaceous age, exposed chiefly in the Benue valley and the Cross river basin, with less extensive outcrops on the northwestern side of the High plains of Hausaland and also along the southern margin of the hilly zone adjoining the coastal lowlands. Upper Cretaceous sediments lie immediately over Basement rocks along much of the Niger valley and overlap the Lower Cretaceous elsewhere; their most important exposure is east of the lower Niger, where they form the rolling country culminating in the Udi escarpment. Mainly sandstones, they give rise there to poor, sandy soils, badly leached and eroded, which in some densely populated districts have been cropped almost to exhaustion. Some of these sandstones are suitable for glassmaking and include clays that could be used for pottery, but the most important mineral of the Upper Cretaceous series is the coal mined principally around Enugu. Limestones, mainly of Lower Cretaceous age, are developed for cement manufacture. Younger sediments are found along the coastal margin (including large unexploited lignite reserves west of the lower Niger), in the northwest and in the Chad basin. Nigeria's commercial oil wells are mostly east of the Niger delta, near Port Harcourt.

Volcanic activity started in the Cretaceous and appears to have been most vigorous in the Tertiary. Extinct cones, sometimes severely eroded, are found in the middle and upper parts of the Benue valley, but the main areas are the Jos and Biu plateaus.

The Basement rocks contain some gold and other minerals, but the mineralized area of the Jos plateau produces abundant tin ore (cassiterite) as well as smaller quantities of associated ores such as wolfram, tantalite and columbite. Small quantities of these ores are also found in the Basement areas away from the Jos plateau.

2. Physiography.—Nigeria can be divided into six relief regions: (1) a low coastal belt which includes the Niger delta; (2) an adjacent hilly belt, rising in places above 2,000 ft.; (3) the valleys of the Niger and the Benue, above their confluence at Lokoja, altitude 250–600 ft.; (4) the broad northern plateau, consisting of stepped plains at altitudes of 600–2,500 ft., with steep-sided inselbergs rising above 4,000 ft.; (5) the Jos plateau, at 3,800–4,600 ft. with peaks rising to over 6,000 ft.; and (6) the eastern highlands rising toward the Cameroons. The main rivers are the Niger (*q.v.*), entering the country in the northwest and flowing first southeast and then south to the Gulf of Guinea; its major tributary, the Benue (*q.v.*), rises in the mountains of the Cameroon republic. Outside the Niger system, the most important river is the Cross (*q.v.*), which flows into an estuary east of the Niger delta. The Jos plateau is an important hydrological centre; from it rivers flow to the Niger, to the Benue and northeastward to the inland drainage basin of Lake Chad.

In the region of the Niger delta the coastal belt reaches its greatest width (about 50 mi.). This is an area of swamp covered with mangrove and freshwater swamp forest, with patches of heavier forest on the islands above flood level. The distributary channels of the Niger form a complicated pattern, which varies from year to year. The coastal belt narrows eastward from the delta; westward it consists of an outer sand beach backed by mangrove, with mangrove and freshwater forest on the northern shores of the coastal lagoons. The tidal range is only three feet at Lagos and increases eastward to nine feet at Calabar. The creeks and lagoons form important waterways.

The hilly belt behind the coastal lowlands is widest in the west, where its northern margin is about 200 mi. from the sea. Eastward it contracts and is crossed by the lower Niger in a narrow valley. The broad western part of this belt resembles the wide stepped plains of the northern plateau, but east of the Niger the landscape is characteristically one of gentle slopes rising to eastward-facing scarps; the Udi scarp, with coals exposed near its base, overlooks the broad plains of the Cross river. Parts of this eastern section have the appearance of open downland, in places badly scarred by huge erosion gullies hundreds of feet deep. The southern margin is wooded, but the forest has been impoverished by periodic clearing to allow cultivation. The drier northern and western margins of the belt are covered with a derived savanna of grassland and fire-resistant trees which have replaced the forest as a result of grass fires after clearing.

The Niger and Benue valleys form a great lowland arc across the country. The rivers and their tributaries are mostly sluggish and in broad open valleys, but whereas the Benue is (in the flood season) navigable to beyond the Cameroon frontier, rapids prevent navigation of the Niger above Jebba. The valleys tend to be oppressive from the high humidity accompanying evaporation from the rivers. The vegetation is mainly savanna woodland.

The northern plateau in its central part consists of broad, stepped plains known as the High plains of Hausaland. Covered with savanna parkland, which thins into scrub along the northern frontier, and with gallery forest following the watercourses, these plains were ideal for cavalry, and there the Hausa and Fulani kingdoms developed and flourished. The soils are superior to those farther south, where the combination of heavy rainfall with a long dry season forms a hard, lateritic surface crust. In the northeast the plains fall to about 600 ft. in the sandy basin of Bornu (*q.v.*), the northern part of which is marked by lines of old dunes. East of the Gongola river and south of the Chad basin the extinct volcanic plateau of Biu rises locally to over 3,000 ft.

The Jos plateau forms the uppermost step of the High plains but may be distinguished by its high bounding scarp (more than 2,000 ft. in places) and by its bare grassland surface. It is also notable for its tin fields, for its many extinct volcanic cones and for the small pagan groups who took refuge there and who executed the impressive terrace farming of the surrounding scarp, particularly in the southeast. The abrupt descent of the rivers from the plateau to the surrounding plains has been utilized for hydroelectric power.

The eastern highlands lie almost entirely in the Cameroons, but outlying hill masses in Eastern Nigeria include the Sonkwala hills, which exceed 6,000 ft. They are forested on the lower slopes, but

the upper slopes are grassed. (J. C. PH.)

3. Climate.—Although Nigeria has a tropical climate throughout, there are marked differences between north and south. The south has more rain, less defined seasons and generally lower daily temperature ranges.

Most of southern Nigeria has a mean annual rainfall exceeding 60 in., occurring chiefly in a rainy season between early April and late October. The rain is brought by storms traveling from east to west and varying in frequency; heralded by towering cumulonimbus clouds which bring a brief burst of wind and rain, easing into an hour or two's drizzle from an overcast sky. Daily temperatures during this season range between 20° and 28° C. (69° and 83° F.) and relative humidities between 75% and 98%. In the southwest there is a brief season in late July and August when practically no rain falls, although high humidities and heavy cloud persist. From November to March is a dry season dominated by daily temperatures between 21° and 32° C. (70° and 90° F.), relative humidities often exceeding 70% and plentiful afternoon cumulus cloud. Thunderstorms occur irregularly, especially in November and March, while on a few occasions between mid-December and mid-February the harmattan (*q.v.*) wind may reduce night temperatures below 18° C. (65° F.) and daytime relative humidity below 40%.

Northern Nigeria's climate is dominated by a dry season from early October to early June. For much of this, daily temperatures range from 15° to 35° C. (60° to 95° F.) and the sky is cloudless. Under the influence of the dust-laden harmattan the air is hazy and relative humidity often falls below 10%. From March onward it grows steadily hotter, especially at night, when humidity increases as the rains approach. These arrive suddenly in heavy thunderstorms which lower temperatures to levels similar to those of southern Nigeria. The rains cease abruptly in late September or early October, and soon the dry season is again established.

The climate of both southern and northern Nigeria is modified locally by highlands. The Jos plateau, for example, is cooler and wetter than its surroundings, and the eastern highlands cooler and wetter than the remainder of Eastern Nigeria. (B. J. GA.)

4. Vegetation.—Broad belts arranged roughly parallel to the equator vary from lush rain forest in the south to arid thorn scrub in the far north. The coastal vegetation consists largely of species that also occur on the Atlantic shores of tropical America. Three species of red mangrove (*Rhizophora*) form extensive thickets and forests in brackish swamps; behind these, in fresh water, the swamp forest is characterized by various trees with breathing roots, such as the raffia palms (*Raphia*), screw pines (*Pandanus*) and the valuable abura timber (*Mitragyna ciliata*).

The rain-forest region is honeycombed with villages and farms. In the best forests the largest trees are 120–200 ft. tall and 10–20 ft. in girth. They include valuable timbers such as African mahogany (*Khaya ivorensis*), African walnut (*Lovoa trichilioides*), guarea (*Guarea cedrata*), sapele (*Entandrophragma cylindricum*), iroko (*Chlorophora excelsa*), obeche (*Triplochiton scleroxylon*) and opepe (*Sarcocephalus diderrichii*). Smaller trees include ebonies (*Diospyros*), kola nut (*Cola acuminata*), camwood (*Pterocarpus* and *Baphia*) and silk rubber (*Funtumia*). Silk-cotton trees (*Ceiba*) and kapok trees (*Bombax*) grow in farmlands and secondary forest, where oil palms (*Elaeis guineensis*) are abundant, especially in the east. Small plantations of edible kola nuts, cocoa and Para rubber are common in the west.

Fallow farmland is soon covered by quick-growing trees and by dense tangles of climbing shrubs which become large lianas when left to grow up with the developing forest. Where tall grass invades the fallows, fierce fires occur almost every dry season, gradually killing the forest species. This happens especially near the northern, drier limit of the forest regions, where wide tracts have become degraded to a savanna type.

The rain-forest region reaches only 50–150 mi. inland. The rest of the country is covered with a more open vegetation of tall grass and of deciduous, fire-resisting trees. At its best the vegetation consists of closed woodland 20–60 ft. tall, but fires and shifting cultivation have caused the trees to be usually rather widely spaced amid the grass. Belts of such savanna run right across northern Africa between the Sahara and the rain forest. In the moister savanna regions tussocky grass 5–12 ft. tall and broad-leaved hardwood trees predominate. In the more arid regions shorter, feathery grass and fine-leaved thorny acacia trees, including gum arabic (*A. senegal*), are widespread. Narrow strips of more or less evergreen forest vegetation fringe the rivers and streams in the savanna regions.

Savanna trees are used mainly as fuel, for rough building poles and for their fruits. Fruit trees common in and around towns and villages are: locust bean (*Parkia*), shea tree (*Butyrospermum parkii*), baobab (*Adansonia digitata*) and tamarind (*Tamarindus*). The fan palm (*Borassus*), the doum palm (*Hyphaene*) and species of *Raphia* occur in the savanna; the date palm (*Phoenix dactylifera*) is found only in towns, but a wild relative, *P. reclinata*, is common along the streams.

With the rainy season the savanna trees come into new leaf, often with vivid tints, fresh grass grows up from the burned ground and numerous bulbous monocotyledons blossom. During the rainy season the grass grows apace and the tree canopy thickens. Toward the end of this season the grasses flower and with them many of the Compositae and other dicotyledonous herbs. During the

dry season the grass is burned and the vegetation remains charred and bare for a few weeks.

Most of the extreme north is covered by a drift of sand formed during arid periods in Quaternary times. The climate has since become moister and the sand has been stabilized by vegetation. But where such ground has been cleared of its natural vegetation the loose sand is easily blown about; whence a belief that the Sahara is encroaching into Nigeria. In fact, the northern boundary of Nigeria is separated from the desert by a wide belt of thorn woodland.

There is little montane vegetation; the best example (in Sonkwala, Ogoja province) has close affinities with that of the mountains of eastern and southern tropical Africa and includes some typically European genera and species. The flora of the Jos plateau also has many affinities with that of east and south tropical Africa. (R. W. J. K.)

5. Animal Life.—The high forest zone is poor in large terrestrial species; the typical hoofed animals are the duikers (dwarf antelopes) and the red river hog. About 12 species of arboreal monkeys live in the forest, sometimes in great numbers; chimpanzees are found locally in this zone. The two most notable primates, the gorilla and the drill, inhabit the dense forest and are largely terrestrial; their range extends into the Cross river area. The manatee and hippopotamus occur in the Niger and Benue rivers, as well as in some of the creek country. The pygmy hippopotamus once occurred in the Owerri area but its present status is unknown.

The bush cow is found close to rivers throughout most of Nigeria and the sitatunga in the swamps of the coastal areas and around Lake Chad. The most important ungulates of the open country are kob, waterbuck, reedbuck, roan and western hartebeest. Three species of gazelle and the scimitar-horned oryx inhabit the driest zones, but the Nigerian giraffe is becoming increasingly scarce and the black rhinoceros has almost certainly disappeared. Elephants, too, have greatly decreased, though still found in some places; the status of other animals is threatened continuously by the steady expansion of farming everywhere. The lion and serval range through savanna woodlands north of the high forest, the cheetah and caracal in the Sudan savanna zone while the leopard is found in small numbers almost everywhere. The commonest carnivores are the mongooses, civets and genets.

Hundreds of species of birds are common, including such tropical families as parrots, hornbills, touracos, barbets, weaverbirds and sunbirds. There are ostriches in the extreme north, together with several species of storks and bustards. The most plentiful game birds are guinea fowl, francolins (bush fowl), green pigeons, ducks and geese. Tsetse flies exclude domestic stock, except some poor sheep and goats, from the forest zone, but horses, donkeys, camels, cows and pigs, as well as numerous sheep and goats, are kept in the north. Reptiles are plentiful both in variety and number, with three species of crocodiles, several turtles and tortoises and many lizards and snakes. The most important snakes are black cobras, green mambas, giant vipers and pythons. Nigeria's rivers and creeks abound in amphibians and fish. Invertebrate life is rich and varied; many species have not yet been described. Butterflies and moths are numerous in forest areas and the massive migration of butterflies is seen in open country. Many species are of outstanding size. There are large scorpions, and the Goliath beetles are among the world's largest insects. (G. S. Ce.)

II. THE PEOPLE

The population of Nigeria is Negro, though with an admixture of other stocks. Limited anthropological surveys show no clear-cut racial divisions. Blood group analyses show that while local differences occur on all systems, the pattern of gene-frequency distribution on any one system does not match that on any other. The most to be said is that the pastoral Fulani (*q.v.*) diverge from the other peoples on more than one (but not every) system, and that the divergency is toward the Mediterranean pattern. The Fulani, who have drifted into Nigeria from the west with their herds for more than 300 years, may indeed have a Mediterranean strain; they regard themselves as white and look less Negroid than other Nigerians. Much variation in physique and pigmentation occurs in the more certainly Negro population; the darkest skins are in the Sudan savanna, where insolation is high, and in the humid and largely forested south are some conspicuously light-skinned populations, notably among the Edo and Ibo (*qq.v.*).

More than 100 languages and dialect clusters (probably all using tone lexically) have been distinguished in Nigeria, but a mere four of them are the mother tongues of 60% of Nigerians: Hausa and Fulani in the north, Yoruba in the west and Ibo in the east. Most of the languages in Northern Nigeria, including Hausa (*q.v.*) the official language, are in the Chad group of the Afro-Asiatic (Hamito-Semitic) family; Arabic, spoken by the 100,000 or so pastoral Shuwa (who are nevertheless reported to be Negro) near Lake Chad, is in the Semitic branch. Kanuri belongs to the central Saharan family. Some of the fishing tribes along the Niger speak a dialect of Songhai, a middle Niger language given the status of a separate family. All southern and some northern languages, including Fulani, belong to the Niger-Congo family (Greenberg's classification). English, the language of commerce and higher education, is widely spoken and understood.

The main cultural and religious contrasts follow the division of the various social systems into Islamic states, typically African states and tribal societies with no centralized political authority. The contrasts are softening under modern conditions and Christian and Muslim proselytizing. Islam, introduced in the 14th century, is professed by 44% of the people and is supreme in Northern Nigeria, where Christian missions in Muslim areas are prohibited. About 34% acknowledge Christianity and only 22% the old tribal religions, which are rapidly losing their hold although traditional beliefs are not always abandoned by converts to Christianity or Islam.

Most of Northern Nigeria is organized into Islamic states: the ancient realm of Bornu (*q.v.*) in the northeast and the old Hausa, Nupe (*q.v.*) and northern Yoruba (*q.v.*) states, which were conquered by the Fulani early in the 19th century and regrouped into emirates under the sultan of Sokoto. All these administer Maliki (Islamic) law. Most of the other states, of which the various Yoruba kingdoms, Benin and the Jukun (*qq.v.*) of the upper Benue are best known, are hieratic city-states headed by a quasi-divine king and usually including cult associations and secret societies in the institutions of government. The few states that emerged in the Niger delta and Cross river estuary during the slave-trade era grafted on to the village organization a political system based on rivalry between powerful trading "houses." Formerly, titled slaves were important officials in all types of state. The tribes without a state system can be small—a few dozen households in the rocky hills of the Jos plateau and other highlands, where they shelter from the raids of nearby states; but the Tiv (*q.v.*) and Ibibio are large tribes and the Ibo form the largest group in Eastern Nigeria. The social organization rests on lineage groups (commonly with ancestor cults) owning tracts of land often centred on Earth-spirit shrines. Closed associations are prominent, as they are in the states, and in both have been models for new political pressure groups.

Western culture has been most readily assimilated by the peoples of Western and Eastern Nigeria where English is the official language; native institutions have not been protected as carefully as those in the emirates of Northern Nigeria. Education of the English sort, provided by government and missions, flourishes in the south and among the non-Muslim peoples of the north. (P. M.-W.)

III. HISTORY

Very little is known of the history of Nigeria, least of all the history of the coastal tribes, before the country was first visited by Portuguese navigators in the second half of the 15th century. A number of Negro tribes occupied the swampy coastal areas and the thickly forested lands which lay immediately behind, while the interior, which became the Northern region of Nigeria, was the home of peoples of mixed Arab, Hamitic and Negro blood. The Muslim religion probably was introduced into this northern area as early as the 13th century and profoundly influenced the social

In 1893 Bornu was invaded by Rabah Zubayr (*q.v.*), with an army better armed and disciplined than that of Bornu, which he completely defeated, making himself the ruler of Bornu. In 1900, however, Rabah was defeated and killed by the French, who were extending their control over the western Sudan.

2. **The Coastal Tribes.**—To the south of Bornu and the Hausa lands were a large number of tribes having various origins and customs and speaking distinct languages. Of these the largest and most important were the Yoruba and the Beni or Bini (*see* BENIN), who occupied what later became the Western region of Nigeria, and the Ibo, in what later became the Eastern region. The Ibo tribe was divided into several clans speaking different dialects and lacking any central organization. For this reason it has practically no known history until after the British occupation. The same could be said of the numerous small tribes which inhabited the forest area and the mountainous areas of the north.

The Beni and Yoruba, on the other hand, had long-established states which at various times reached a much higher standard of organization and culture than the other purely Negro peoples attained. When the first Portuguese ships reached the Nigerian coast in the 15th century, the Beni had long been an important nation, and the *oba* (king) of Benin was a powerful monarch whose authority extended over the Yoruba country and even farther west. Friendly intercourse and a certain amount of trade, mainly in slaves, were established between the Portuguese and the Beni. But the tribe gradually declined in power as the *oba* came under the influence of a theocracy of fetish priests who maintained authority by the terror created through wholesale human sacrifices. They discouraged contact with Europeans, trade dwindled, and by the beginning of the 18th century Benin had lost influence.

In the meantime the Yoruba (*q.v.*) had risen in importance. Little is known of their origin, but they supposedly came from the northeast and perhaps from upper Egypt. The first settlement of the Yoruba in Western Nigeria was probably at Ife (*q.v.*), which was to remain the spiritual headquarters of the people. The *alafin* of Oyo was originally the ruler of the whole tribe, but about 1810 the breakup of his kingdom began, each clan, under its own king, becoming practically independent although the *alafin's* nominal suzerainty continued to be recognized. The country was greatly weakened and suffered from repeated invasions from Dahomey, while the northern province of Ilorin (*q.v.*) fell to the Fulani from the north. The different clans—Oyo, Egba, Ife, Ijebu and others—became involved in internecine wars, prisoners of which were sold at Lagos as slaves.

3. **The Slave Trade.**—Traffic in slaves begun by the Portuguese proved so lucrative that other nations were soon in competition and the slave ships of several European nations flocked to the Guinea coast. British ships were visiting the coast of Nigeria by the 17th century. Much of the trade was with minor chiefs and tribes in the Niger delta and on the banks of other rivers, the slaves being obtained by these middlemen from the interior. Payment was made for the slaves in potable spirits and arms and ammunition, which encouraged intertribal warfare and debased the people. Throughout the long period of unrestricted slave trade no European nation attempted to bring any part of Nigeria under its control.

The slave trade was made illegal for British subjects in 1807 (*see* SLAVERY) but the trade was scarcely affected as ships of other nations continued to carry cargoes of slaves across the Atlantic. A British naval squadron was then stationed on the west African coast to intercept the slavers. British merchant ships continued to visit the estuaries of the Nigerian rivers and began a legitimate trade, buying palm oil and other products. This fact and the activities of the naval squadron greatly increased British influence among the coastal tribes.

4. **Exploration.**—At that time little was known of the interior of Africa, and it was not even appreciated that the numerous streams of the Niger delta were in fact the mouths of a great river. Existence of such a river had long been known, but its general direction and outlet were matters for speculation. Several explorers failed before Mungo Park, in 1796, established the fact that the general course of the upper Niger was easterly. Park lost his life

at the end of 1805 or early in 1806 in an attempt to follow up his first discovery. It was not until 1830 that the brothers Richard and John Lander ascertained that the Niger flowed into the Gulf of Guinea, through the delta which had been known to Europeans for more than 300 years. (*See* NIGER RIVER.)

Other explorers reached northern Nigeria by traveling across the Sahara from Tripoli. In 1823 Dixon Denham and Hugh Clapperton (*qq.v.*) reached Bornu, where they were received by the *mai* and by the *shehu* Lamino. They then visited Sokoto and met Sultan Bello, returning safely to England in 1825. Clapperton died near Sokoto in 1827 on a second journey made from the Bight of Benin. Another extensive exploration was carried out by the German Heinrich Barth (*q.v.*) on behalf of the British government. He crossed the Sahara in 1850, visited Bornu and the Hausa lands and returned safely across the desert in 1855.

Meanwhile an attempt had been made to follow up the discovery of the Lander brothers by a trading venture on the Niger to provide an alternative to the slave trade. A company was formed by a Liverpool merchant, Macgregor Laird (*q.v.*), who went in 1832 with two small steamers to a point above Lokoja, but disease decimated the crews and the expedition was abandoned. In 1841 a large party, including missionaries, was sent by the British government in four ships, under the command of naval officers, to explore the Niger and to try to make treaties for stopping the slave trade. In two months there were 48 deaths out of 145 Europeans in the ships, while a number of others became seriously ill, and this enterprise also was abandoned. It was not until 1854 that a single ship, commanded by W. B. Baikie (*q.v.*), with a crew composed largely of Africans, was able to explore the Niger and the Benue and to do a certain amount of successful trading without any loss of life, the success resulting from the prophylactic use of quinine.

5. The Beginnings of British Rule.—By that time the trade in palm oil, which the coastal Africans found remunerative, had greatly increased, while the slave trade declined in the Niger delta and on the Oil rivers to the east of it, although it was not until about 1840 that slave ships stopped visiting these rivers. To assist legitimate trade it was decided in 1849 to appoint a British consul for the Bights of Biafra and Benin, with his headquarters at Fernando Po. Selected for this post was John Beecroft, who had resided at Fernando Po for many years as superintendent of the naval base there.

Beecroft was soon engaged in negotiations with King Kosoko of Lagos (then the principal port in west Africa from which slaves were shipped) with a view to stopping the trade; but the negotiations were unsuccessful, and in 1851 the town was attacked by a naval force and captured after heavy fighting. Kosoko fled, and his uncle Akitoye, the legitimate ruler, was placed on the throne; he signed a treaty providing for the abolition of the slave trade and of human sacrifice and for the protection of missionaries. A British consul was appointed to Lagos with the king's consent.

In 1861 Akitoye's successor, Dosumu, who appeared unable to govern effectively or to prevent the revival of the slave trade, was required to sign a treaty ceding his possessions to the British crown in return for a pension, and Lagos was annexed as a British colony. For a time the existence of this colony, which effectively stopped the slave trade and provided a haven for runaway slaves, was strongly resented by the Yoruba in the hinterland of Lagos and especially by the Egba, who closed the trade routes and expelled all missionaries and European traders. At a later date, however, British influence increased in the Yoruba country; the civil wars which had raged for so many years among the Yoruba were brought to an end, and in 1888 a treaty with the *alafin* of Oyo placed the whole of the Yoruba country under British protection.

After his successful voyage in 1854 Baikie had established himself at Lokoja under the protection of the amir of Nupe and maintained his more or less official settlement from trading profits. A number of European companies also began to trade on the Niger. In 1879 George Goldie-Taubman (later known as Sir George Goldie; *q.v.*), who was interested in one of the companies, arranged a merger of all the British firms trading on the Niger; and a few years later he was able to buy out the rival French companies. Treaties were made with the chiefs of tribes inhabiting the banks of the Niger and the Benue and with the Fulani sultan of Sokoto, and at the Berlin conference of 1885 it was possible to claim that British interests were supreme on the Niger and the Oil rivers. This claim was admitted by the conference, and a British protectorate was then declared over the Niger districts, which included the Oil Rivers area and the hinterland.

The vague authority of the consul had gradually increased in the Oil Rivers area, and courts of equity, composed of the leading African and European traders on the different rivers, had been established. In 1872 an order of the queen in council had regularized the judicial and administrative position of the consul, but he had for a time little means of enforcing his authority. In 1887, however, Chief Jaja of Opobo was removed and deported in consequence of his interference with trade and defiance of the consul. In 1891 a commissioner and consul general was appointed to the Oil Rivers, with his headquarters at Calabar, and in 1893 the territory was renamed the Niger Coast protectorate.

6. The Royal Niger Company.—In 1886 a royal charter was granted to the company organized by Sir George Goldie, which later was called the Royal Niger Company, Chartered and Limited. The company was authorized to administer the delta and the country on the banks of the Niger and the Benue together with the hinterland but was forbidden to establish any monopoly of trade. The company at once set up courts of justice and the usual administrative services and raised an armed constabulary. Most of the Fulani empire was beyond its control; but in 1897, after a short campaign, the company's troops were able to subdue Ilorin and Nupe and to compel the amirs of these states to abandon slave raiding and recognize the suzerainty of the company.

Meanwhile, on the coast, the people of Brass—who were included in the Niger Coast protectorate and excluded (except on payment of prohibitive dues) from trading in their former markets on the Niger which lay within the company's territory—became increasingly hostile. In 1895 they raided the company's establishment at Akassa, killing many of the African employees of the company and carrying off others as prisoners, some of these being killed and eaten. This outrage was punished by a naval force.

7. Benin.—Another naval force, assisted by the protectorate constabulary, had captured (1894) Brohemie, on the Benin river the headquarters of the Jekri chief Nana, who had traded in slaves extensively. Nana was captured, tried and deported.

The principal centre of the slave trade in the Niger Coast protectorate was then the city of Benin, which was also notorious for human sacrifices. King Overami of Benin had failed to implement a treaty he had signed in 1892 for the abolition of human sacrifice and of the slave trade, and the acting consul general, J. R. Phillips, suggested that he should visit Benin to discuss the matter. The king replied that he would be willing to receive Phillips within a few months' time, but Phillips was not prepared to wait and decided, in spite of warnings, to go at once to Benin. He so informed the king, assuring him that his party would be unarmed. On in reply Overami promised to send guides to meet the party. Jan. 3, 1897, Phillips and his party landed at Gwato, where a friendly welcome was received through messengers sent by the king. The next day, however, the party started for Benin and within a few hours it was attacked and massacred, only two of the Europeans, badly wounded, and a few of the Africans escaping. Phillips and six of his European companions and more than 200 Africans perished.

A naval force was at once sent to the Benin river, and sailors and marines, with troops of the protectorate constabulary, captured Benin after severe fighting, about six weeks after the massacre. After a judicial inquiry, those who were directly responsible for the massacre were executed and Overami was deported.

8. Northern and Southern Nigeria.—On the western frontier, disputes with France (which were to be embittered in 1898 by the Fashoda crisis at the opposite end of the Sudan) nearly led to war, and an imperial force of African soldiers with British officers, the West African Frontier force, was raised in 1897 and placed under the command of Frederick Lugard (*see* LUGARD, FREDERICK JOHN DEALTRY LUGARD, 1st Baron). For a time the

situation was critical, but the dispute was finally settled without fighting. (*See* BORGU.)

These international difficulties and the complaint of the Brass people against the Royal Niger company led to the revocation of the company's charter, the British government assuming direct control of the company's territories on Jan. 1, 1900. The land in the Niger delta and along the lower reaches of the river, which had been included in the company's territories, was added to the Niger Coast protectorate, which was renamed Southern Nigeria. On May 1, 1906, the Lagos territories were amalgamated with Southern Nigeria, the whole country being styled the Colony and Protectorate of Southern Nigeria, with Lagos as the seat of government.

The northern part of the company's territories became the Protectorate of Northern Nigeria, with Lugard serving as the first high commissioner. The Fulani amirates still retained their independence, and slave raiding continued; but the principal slave raiders, the amirs of Kontagora, Nupe and Adamawa, were removed from office in 1901, and Bauchi and Bornu were brought under control the following year. The sultan of Sokoto refused friendly overtures. In spite of this the British administration was steadily extended, and a small garrison was stationed at Zaria. When the amir of Kano threatened to attack this garrison and also refused to surrender the murderer of a British official, a force of about 700 African soldiers, with British officers, advanced against the mud-walled city of Kano, which was taken with little difficulty on Feb. 3, 1903. There was subsequently severe fighting against the main Kano army and the army of the sultan of Sokoto, who fled before the battle. Sokoto was then occupied, and the chiefs nominated a new sultan, whose appointment was approved by the high commissioner.

The sultan and amirs who accepted British rule were installed with full ceremonial after agreeing to abolish slave raiding and to be guided by the advice of British officials. In return they were promised their religion would not be interfered with and that the existing system of Muslim law would be retained. Most of these amirs remained loyal and proved efficient administrators under British supervision. A rising of a few fanatics against the sultan of Sokoto in 1906 was suppressed by protectorate troops, and there was some fighting against the pagan tribes who resisted the enforcement of law; otherwise there was little serious trouble, and British administration was quickly made effective throughout Northern Nigeria. Slave raiding was suppressed and the legal status of slavery was abolished, although many slaves remained voluntarily with their masters.

In the administration of Northern Nigeria, Lugard used the indigenous authorities, the amirs and other chiefs, in what became known as indirect rule. The African administrations had their own treasuries and received a proportion of the tax.

9. The Amalgamation of Nigeria.—Lugard ceased to be high commissioner in 1906 but returned to Nigeria in 1912 as governor of both Northern and Southern Nigeria, charged with the duty of amalgamating the two territories. This amalgamation was effected on Jan. 1, 1914, the whole country being known thereafter as the Colony and Protectorate of Nigeria.

Seven months later, in Aug. 1914, World War I broke out, and Nigerian forces were soon in action against German troops in the Kamerun (*see* CAMEROONS). A combined Franco-British invasion of the Cameroons resulted in the conquest of the country by the beginning of 1916. In 1922 a small part of the Cameroons was mandated by the League of Nations to the United Kingdom and was attached for purposes of administration to Nigeria. (The mandate was replaced in 1947 by a trusteeship agreement with the United Nations.) Before the end of the war Nigerian soldiers had also taken part in the fighting in east Africa. In World War II, Nigerian troops served in east Africa against the Italians and in Burma against the Japanese.

10. Constitutional Changes.—Following the amalgamation of 1914 and particularly after the end of World War II, a number of territorial and constitutional changes took place in Nigeria. In 1914 the country was divided into three main areas, namely the Colony of Nigeria (corresponding to the former Colony of Lagos) and two groups of provinces in the protectorate, the Northern and Southern provinces. The Southern provinces were later divided into two groups, Eastern and Western. In 1951 these were officially renamed the Northern, Eastern and Western regions.

In 1914 a legislative council for the colony alone had been set up, affairs of the protectorate being beyond its purview. In 1923 a larger legislative council was established which for the first time included a limited number of elected members.

A radical change was made in the constitution of Nigeria in 1947. Houses of assembly for the three groups of provinces were set up, and there was also a house of chiefs for the Northern provinces. In each of the houses of assembly nonofficial members were in a majority over ex officio members. In addition there was a central legislative council for the whole of Nigeria.

Public opinion was still not satisfied, and a quasi-federal constitution, introduced in 1951, provided for a central legislative house of representatives. Resulting friction between central and regional legislatures caused the introduction of yet another constitution (the third in eight years) in 1954. This set up the Federation of Nigeria, comprising the Northern, Eastern and Western regions, the Southern Cameroons (part of the trust territory) and the Federal Territory of Lagos. A fourth region, the Mid-West, was established in 1963, by the separation of certain non-Yoruba areas from the Western region. The office of federal prime minister was created in Aug. 1957 (the post being filled by Alhaji Abubakar Tafawa Balewa, a northerner) as a result of the constitution conference of 1957–58, and internal self-government was achieved by the Eastern and Western regions in 1957, by the Northern in 1959.

The British government then announced its willingness to grant independence to the federation on Oct. 1, 1960, and on the request of the Nigerian federal legislature this undertaking was implemented by the United Kingdom parliament. On June 1, 1961, the northern part of the Cameroons trust territory joined the federation as part of the Northern region. Southern Cameroons united with Cameroun on Oct. 1, 1961, to form the Federal Republic of Cameroon. On Oct. 1, 1963, Nigeria became a republic.

11. Independent Nigeria.—Owing to the larger population and consequent greater representation of the Northern region in the federal legislature, the central government was largely under northern control and this was resented by the southern tribes. In May 1962 a political crisis occurred in Western Nigeria. There were disorders and electoral boycotts during the general elections of 1964, the first to be held after independence, and in Oct. 1965 further disorders took place in the Western region when a regional election was held there. There was strong evidence that this election was rigged by the political party in power, which was allied to the party that controlled the Northern region and, to some extent, the federal government.

In Jan. 1966 an army mutiny led by officers of the Ibo tribe overthrew the civil government and culminated in the death of the federal prime minister and the premiers of the Northern and Western regions. A military government was set up under Maj. Gen. Johnson T. U. Aguiyi-Ironsi, the officer commanding the Nigerian Army, who, himself an Ibo, had not been implicated in the mutiny. Attempts by the military government to abolish the regions and establish a unitary government led to disorders in the Northern region and to the killing of Ibos living and working there. At the end of July 1966 in another military coup, by Hausa officers, General Ironsi was killed and a new military government came into power under Lieut. Col. Yakubu Gowon, a northerner. Subsequently many Ibos were killed in the Northern region, and a movement of Ibos back to their homes in the Eastern region took place. Some Hausas were killed in the Eastern region.

On Sept. 12 representatives from all four regions and Lagos met to attempt to work out constitutional provisions that would make possible return to civil government. No agreement being reached—the Eastern region insisting on a weak central government—the meeting adjourned on Oct. 2. When it reassembled on Oct. 27, no delegate from the Eastern region was present, and the other delegates gave up in mid-October. Gowon on November 30 declared his determination to maintain the unity of the country, but on May 30, 1967, the Eastern region seceded and declared itself the Republic of Biafra. (A. C. Bs.; X.)

IV. POPULATION

The census conducted in 1952–53, the second to be held in Nigeria (the first was in 1931), gave the total population as 29,730,879. In 1960 it was estimated at 35,091,000. The results of the 1962 census were nullified and, according to the 1963 census, the total population was 55,670,052.

The distribution is uneven, with marked concentrations in each of the three regions. Densities of more than 700 persons per square mile exist in the Ibadan province of Western Nigeria, more than 800 in Owerri province in the Eastern region, and nearly 350 in Kano province in the Northern region. Over most of the middle belt of central Nigeria densities are less than 100 per square mile and large areas are virtually uninhabited.

About 10% of the population is urban. Most of the largest cities are in the Yoruba country; they include Lagos (the federal capital), Ibadan (capital of Western Nigeria), Ogbomosho, Mushin, Oshogbo, and Abeokuta. In Eastern Nigeria there are few large towns; they include Port Harcourt, Onitsha and the regional capital Enugu. Principal towns in Northern Nigeria are Kano, Ilorin, Zaria and the regional capital Kaduna. (X.)

V. ADMINISTRATION AND SOCIAL CONDITIONS

1. Constitution and Government.—The constitutional instruments that came into force on Oct. 1, 1963, provided for a federal republic consisting of the Federal Territory of Lagos and the regions of Northern, Western, Eastern and Mid-West Nigeria (*qq.v.*). The constitution sanctioned the establishment of further regions and the alteration of regional boundaries. Regional governments could execute and maintain their own constitutions and make laws within the region, but not so as to prejudice federal authority. The Mid-West region was constituted in 1963.

The head of state was a nonexecutive president elected to office for five years. The federal government included the council of ministers, the senate and the house of representatives, the last two forming the federal parliament. The council of ministers consisted of a federal prime minister and a number of ministers who might either hold portfolios or be ministers of state attached to ministries. Cabinet meetings were presided over by the prime minister, and the council decided policy. The prime minister was appointed by the president from the majority party in the house of representatives; members of the council were appointed on the advice of the prime minister.

The house of representatives consisted (1963) of 312 members elected for five years by full adult secret ballot, except in Northern Nigeria, where only males might vote. The house was presided over by a speaker appointed from among its members. The senate consisted of 56 members: 12 from each region, 4 from Lagos and 4 selected by the president on the advice of the prime minister.

Bills must be passed by both houses before being sent to the president for assent. Bills might originate in either house, except that the senate might not originate money bills and had limited delaying powers over other bills. The exclusive jurisdiction of the federal government embraced archives, aviation, external borrowing, control of capital issues, currency, defense, external affairs, immigration, maritime shipping and navigation, mines and minerals, museums, armed forces, telecommunications, trunk roads, railways and certain institutes of higher education.

Each region was subdivided into provinces (*see* Table), had its own constitution and had a bicameral legislature consisting of an elected house of assembly and a nominated house of chiefs. An individual could not be a member of a regional house and of the house of representatives. Each region had a premier and ministers and each parliament functioned similarly to the federal parliament, except that bills received assent from the regional governor. Regional authority extended over a "concurrent list" of matters which may have extraregional application and also over health, education, local government and development, local taxation and regional and local administration. Local authorities were in turn responsible for many social and economic services from which they derived revenue.

Northern Nigeria's provincial government was based on former traditional local authorities (rulers and their courts) but the elective principle was gradually being introduced. In the other regions traditional authorities had been largely replaced by local elected councils based on English models. The traditional chiefs were usually presidents of their local councils and were thus integrated into the system. The municipality of Lagos and other large towns (Ibadan, Enugu, Onitsha, Port Harcourt, etc.) were elected by adult suffrage. Civil-service functions were performed by officials controlled by regional public-service commissions, which were constitutionally established nonpolitical bodies empowered to appoint, promote and discipline public-service officials.

Political Parties.—The main parties are the Northern People's Congress (N.P.C.), based on Northern Nigeria; the Action Group (A.G.) and the United People's party (U.P.P.), based on Yoruba-speaking Western Nigeria; and the National Convention of Nigerian Citizens (N.C.N.C., formerly the National Convention of Nigeria and the Cameroons), based on Ibo-dominated Eastern Nigeria. The N.P.C. and the A.G. were formed in the late 1940s but the N.C.N.C. dates back to 1944 when its founder, Nnamdi Azikiwe, joined forces with Herbert Macaulay, "the father of Nigerian nationalism." The U.P.P. was formed in 1962 following a split in the A.G.

2. Taxation.—Most revenue is derived from import and export duties, affecting the prices of

‡Former Northern region of British Cameroons.
§Figures for Mid-West Nigeria have been deducted.

consumer goods and living costs; but from 1961 new scales of direct tax included many income earners hitherto exempt. Anyone with a deducible income became liable to pay a fixed rate of up to £N3, on incomes up to £N300, above which tax was levied on a graduated scale of up to 15*s.* in the pound. This had the effect of including women trading in their own right and the small farmers dependent on the sale of export produce.

3. Living Conditions.—These vary considerably between town and country. Major projects operate in the larger towns to clear congested areas, but the heavy expenditure involved and the drift of people from the rural areas retard efforts to raise living standards and to provide full employment. In rural areas there is a gradual provision of clinics and maternity centres but little change in the basic pattern of life. Contrasts range from modern air-conditioned residences of towns and villages served by electricity to mud-built villages in forest or rocky plateau.

Health.—The general level of health and the eradication of disease pose formidable problems, as the ratio of doctors to population is only about 1:35,000. Nevertheless, by the 1960s curative and preventive services were making headway through new hospitals and the building of dispensaries, maternity homes and clinics in all areas. There are localized campaigns to eradicate malaria, sleeping sickness, river blindness and other major tropical diseases, with help of units of the World Health organization and of the United Nations Children's fund, and local preventive campaigns against smallpox, yaws and tuberculosis. Health education occupies a prominent place in planning.

4. Trade Unions.—Development of trade unions is officially encouraged to harmonize employer-worker relations, but most existing unions have been formed as groups of employees within a specific firm or organization and not on the basis of trades. Most unions are affiliated to the United Labour congress. By the early 1960s there were 400 trade unions with 200,000 members.

5. Justice.—The federal supreme court is the highest, possessing original jurisdiction and appellate functions; it consists of the chief justice of the federation, at least three federal justices and the chief justice of each region. Each region, including Lagos, has a high court of justice comprising a chief justice and six regional judges (five in Lagos). Power to appoint officers in the judiciary rests with the president in each region. Customary courts (and Muslim courts in Northern Nigeria) exist alongside magistrates' courts presided over by qualified lawyers. The constitution contains entrenched clauses safeguarding fundamental human rights.

Police.—The Nigeria police is responsible for maintaining law and order and consists of about 14,000 officers and men, with a few women police. Former local authority police forces have been brought under the control of the Nigerian police.

6. Education.—Schooling was brought to Nigeria by the Christian missions, and most leading personalities of modern Nigeria (except Muslims) were educated in mission schools. In the early 1960s these schools provided over 50% of the primary and secondary education in the country. They receive government grants-in-aid and it is official policy for governments to take the controlling part in the educational system.

Universal primary education for children from the age of six years was introduced into Western Nigeria in 1955 and into the federal capital of Lagos and Eastern Nigeria in 1957. By the early 1960s there were about 16,000 primary schools with 3,000,000 pupils. But of these only about 250,000 pupils were in Northern Nigeria, where universal primary education was confined to an area of Kano authority, though it was hoped that by 1970 at least 50% of all children of school age in Northern Nigeria would be at school.

During the same period there were about 290 secondary grammar schools with 50,000 pupils, while Western Nigeria had in addition 420 secondary modern schools with about 65,000 pupils. Teacher-training institutions exceeded 300 with about 27,000 students (one-third of them women) and vocational and technical institutes numbered 44 with 8,000 students. The normal primary course is six years and the grammar school and technical courses are from four years. Evening classes are held at many technical institutes and regional governments conduct mass literacy campaigns to reach the older generations.

To fill the many vacancies for Nigerians in the professional and technical spheres, governments award numerous scholarships, tenable inside Nigeria and overseas in subjects ranging from architecture to zoology. Such scholarships normally entail an obligation to accept government service for five years on qualifying.

Within Nigeria the University college, Ibadan, was opened in 1948. Attached to it is a teaching hospital providing training for doctors and nurses to degree standards. The college was associated with the University of London but in 1963 it became an independent university, awarding its own degrees. The University of Nigeria was opened in 1960 at Nsukka, Eastern Nigeria, and the University of Ife in Western Nigeria was founded in the following year. In 1962 the federal government opened the University of Lagos, and Northern Nigeria established the Ahmadu Bello university at Zaria. By 1970 the university population was scheduled to reach 10,000. The new universities absorbed the branches at Zaria, Enugu and Ibadan of the Nigerian College of Arts, Science and Technology, which had degree courses in engineering and professional subjects. Within the federation there are about 25 public libraries controlling a stock of 350,000 volumes.

7. Defense.—The Nigerian army, formerly the Nigeria regiment of the Royal West African Frontier force, became a separate command as the Nigerian Military forces in 1956. On the declaration of the republic it was redesignated the Nigerian army. Its strength of about 7,000 comprises five battalions of the Queen's Own Nigeria regiment, a reconnaissance squadron, engineers, signals and normal administrative services. There are an officer-training school and a boys' company. The army has a list of battle honours dating back to the Ashanti Wars of the 19th century and which include the Burma campaigns of World War II. The Royal Nigerian navy, established as the Nigerian Naval force in 1958, consists of a frigate and a number of patrol vessels based on Lagos. A Nigerian air force was created in the early 1960s. (W. H. I.)

VI. THE ECONOMY

1. Production.—Like other countries of tropical Africa, Nigeria is dependent upon primary production. The economy is based on agriculture and likely to remain so; 80% of the working population is directly engaged in agriculture. Subsistence agriculture is still important in many parts but is being progressively modified by increasing internal trade and by expanding production for export. Agriculture is almost entirely small scale. Farmers cultivate on an average three to four acres, but total land requirements are greater to allow for fallow periods to restore fertility. Staple food crops are roots (yams and cassava) in the south and cereals (guinea corn and millets) in the north, with a considerable overlap of these crops in the central parts. Trypanosomiasis restricts livestock (particularly cattle) to the northern part of Nigeria.

Major cash crops for export are cocoa, oil palm products and rubber in the south and peanuts and cotton in the north. Nigeria makes a substantial contribution to world trade in some of these products. From the southern parts of the country hardwood timbers (obeche, abura, sapele) are exported, this trade having increased markedly since World War II.

Tin and columbite are mined chiefly on the Jos plateau, and poor-quality coal is mined near Enugu. Oil and natural gas in commercial quantities were found in the Niger delta in 1959, and production, with refining facilities at Port Harcourt, has expanded rapidly. There is much low-grade iron ore. Electric power generation is from petroleum, natural gas, coal or timber fuel. Some hydroelectric power is generated on the Jos plateau, and the Kainji dam project on the Niger upstream from Jebba was scheduled for completion in 1968.

Industrial development is restricted mainly to secondary industry and includes textile manufacture, oilseed crushing, sawmilling, and production of soap, margarine, plywood and furniture, canning of meat and fruit, brewing and manufacture of soft drinks and cigarettes, light metal fabrication, automobile and truck assembly, tire manufacture and cement production.

Fish is an important source of protein, and more than 150 vari-

eties are found in Nigeria's rivers, lagoons and creeks. Bonga nets are used along the coasts, and sea fishing is carried on by commercial trawlers, based at Lagos. Development of local inland and sea fisheries is encouraged by federal and regional authorities.

2. Trade and Finance.—Internal trade is chiefly in foodstuffs, particularly food staples, palm oil, kola nuts and dried fish. Cattle brought on the hoof from the north provide limited supplies of meat in southern Nigeria. The chief Nigerian imports in order of value are manufactured items, including textiles, machinery, foodstuffs, chemicals and fuels; about one-third come from the U.K. About two-thirds of exports by value are made up by petroleum, cocoa, peanuts and palm oil and kernels; other leading exports are cotton, rubber, timber, tin, hides and skins, and bananas. The U.K. takes the largest share of Nigerian exports, followed by the Netherlands, the Federal Republic of Germany and the United States. During the years immediately before and after independence, imports increased mainly through increased spending on capital equipment, while the low world prices for primary products failed to bring a corresponding increase in export income. In 1965, however, there was a balance of payments surplus due to improved exports. Agricultural exports are controlled by statutory marketing boards which use their reserves to subsidize producer prices and to finance research and development.

The Central Bank of Nigeria is the bank of issue, and the currency is based on the Nigerian pound (£N), linked at par with sterling by statute. General banking facilities are provided by both foreign and Nigerian banks. There is a stock exchange at Lagos. Revenue is derived from import and export duties and from income tax collected on a regional basis. A proportion of the total is allocated to the regions and the remainder retained by the federal government. More than £100,000,000 ($280,000,000) was spent on capital development during 1958–62, derived from loans from the World bank and from the U.K. Further economic expansion under the National Development plan for 1962–68 provided for an expenditure of more than £N700,000,000 ($1,960,000,000), of which about 60% was to be capital expenditure. £N150,000,000 ($420,000,000) was spent in the first two years, and the growth rate was higher than that projected.

3. Communications.—Railways, of 3-ft. 6-in. gauge and mainly single tracked, run inland over a total distance of about 2,500 mi. (4,000 km.) from Lagos and Port Harcourt to Kaduna, Jos and Kano, with railheads at Kaura Namoda, Nguru and Yerwa-Maiduguri. The road network covers about 40,000 mi. (64,400 km.), but only about 5,000 mi. (8,000 km.) are tarred and some routes are impassable during the wet season. Kano has for centuries been a great market and a focus of caravan routes from the Sahara and the Sudan. Navigation on both the Niger below Jebba and on the Benue, other than by canoe, is restricted to flood periods. Lagos (Apapa) and Port Harcourt are the chief ports. The Nigerian National line, formed in 1959 with Nigerian interests as majority shareholders, is one of about 30 shipping lines providing regular services between Nigeria and other parts of the world. International air services from Lagos and Kano are scheduled by several companies, including Nigeria Airways, which also maintains internal services. Radio broadcasting (including television) is conducted by federal and regional corporations. The press is the most highly developed in west Africa. *See* also references under "Nigeria" in the Index. NIGER RIVER, the greatest river of west Africa and the third longest of the continent (2,600 mi.) after the Nile and the Congo, drains an area of about 580,000 sq.mi. Apart from its common name Niger (probably from the Latin *niger*, "black," though possibly from the Berber *n'eghiren*, "stream") it is also known in its upper section by the Mandingo name Djoliba (Joliba), meaning "the great big river," and as the Kworra (Quorra, Kovarra or Kwara) farther downstream. The latter names were more widely in use during the 19th century.

The headwater streams of the Niger rise in the Fouta Djalon plateau in the Republic of Guinea near the frontier with Sierra Leone, at an altitude of about 2,500 ft. and less than 200 mi. from the Atlantic ocean. This area is referred to by the French as the "château d'eau" since it also has the sources of the Senegal and Gambia rivers and several streams that flow southwest and south. Much of the area traversed by the Niger in its long course to the sea in the Bight of Benin is composed of old crystalline rocks. The river, however, because of recent earth movements, changes in climate and river capture, exhibits many features of youthful development. Its profile is broken with stretches of falls and rapids and with fast-flowing water in narrow sections alternating with broad, open valley sections with a slow-moving stream. In width the river varies from a few hundred feet to a maximum of nearly two miles at the confluence of the Benue.

From its source the Niger flows in a general northeasterly direction through Mali toward the Sahara, and then turns in a great bend immediately below Tombouctou to flow to the east and southeast at Bourem, across the Republic of Niger and into Nigeria as far as the Benue confluence, and from there southward to the sea. These changes in direction are in part the result of two river systems which were originally distinct from one another. The upper section of the Niger at one time flowed out through the Senegal river and at a later stage terminated in a system of lakes, swamps and channels, the remnants of which now form the "inland delta" between Ségou and Tombouctou. This was joined in the Quaternary era to the present middle and lower sections of the river whose headwaters were at one time in the now arid regions of the Sahara. During and after the wet season floodwaters spread out in the "inland delta" to cover an area the size of England and Wales. In this section the Niger receives a major tributary, the Bani, which joins it at Mopti. Windblown accumulations of sand from the Sahara impede the flow of the river in the vicinity of Tombouctou causing a progressive diversion of the river course southward, and at Gao dry beds on the left bank of the river are evidence of former courses. Downstream from Tombouctou until it enters Nigeria the Niger receives few tributary streams and for some of the way the desert impinges directly on its left bank. The valley section to Yelwa varies, being broad and open where it is cut in Tertiary sandstones, and narrow and enclosed where the stream is flowing over crystalline rocks. Between Yelwa and Jebba there is a series of rapids extending for about 50 mi. The best known of these are at Bussa and they are in places virtually impassable even by canoe. They effectively cut off the middle from the lower section of the Niger. Upstream from Yelwa the Niger is joined by the Kebbi river, the first of its major Nigerian tributaries which all flow in from the north. At Mureji between Jebba and Lokoja, the Kaduna unites with the Niger which at Lokoja receives the Benue (*q.v.*), the greatest tributary of all and itself one of the major rivers of Africa. For some distance south of Lokoja the Niger flows in a restricted valley ex-

closed by hills and in some places flanked by sandstone cliffs up to 150 ft. high. The valley then opens again, and some way below Onitsha the great Niger delta begins. This is the largest delta in Africa and covers an area of 14,000 sq.mi. It extends along the coast for about 120 mi. from Forcados to Port Harcourt and inland for 140–150 mi., and is an area of innumerable interconnecting waterways and mangrove swamp, difficult to traverse and for the most part undeveloped. The main outlet channel of the delta is the Rio Nun. The delta is being gradually extended seaward by the increments of silt brought down by the river.

Navigation.—The broken profile of the river with its falls and rapids has prevented uninterrupted navigation. In the considerable navigable stretches, the flow of water fluctuates with the seasonal variations of the several rainfall regimes which control the amount of water entering the main river and its tributaries. The upper Niger is navigable from Kouroussa in Guinea to Bamako in Mali from July to October. Below Bamako there are the Sotuba rapids which are followed by a navigable stretch of about 1,000 mi. entirely within Mali from Kulikoro to Ansongo. This is open for vessels, other than canoes, from late July or August until December. There is a considerable time lag in the movement of flood water downstream, particularly with the slow progress of water through the "inland delta." Water from the previous wet season in the upper Niger does not reach the Djerma Ganda region (Republic of the Niger) in the middle section until mid-January, and Jebba in Nigeria until a month or more later. It is estimated that it takes a little less than a year for water from the upper reaches of the river to pass down to the sea. The flow of water near the mouth is never less than 1,000,000 cu.sec., which is about three times the maximum flow at Kulikoro. From Ansongo to Jebba in Nigeria the river is unnavigable, except for short stretches; *e.g.*, for 75 mi. between Niamey and Gaya. Below Jebba navigation is uninterrupted by falls or rapids but river craft, canoes excepted, are dependent on the amount of water in the river. At Jebba, apart from the upper Niger floodwater, there is local floodwater in the river from early August until mid-November. Powered vessels can operate this far upstream (550 mi. from the sea) from August to February. They can operate to Baro (400 mi. from the sea) from July until March. Below the Benue confluence at Lokoja (332 mi. from the sea) the river is open all the year, though operations are restricted in April and May when the flow of water is less than at any other time. With the best water conditions the greatest permissible draft for fully loaded vessels is 7 ft. 6 in. These are power-driven craft towing barges alongside. The journey from the delta to Baro takes eight days, and the return journey six days.

At Baro the river transport is linked with the Nigerian railway, through the 111-mi. branch line which joins the Lagos-Kano line at Minna. Burutu and Warri are the two ports in the delta which link the river transport with the sea. Both are approached from the sea by way of the mouth of the Forcados river. There a sandbar has limited the size of ships entering and leaving and the amount of cargo they can carry, but a channel was to be dredged in the 1960s to accommodate ships of up to 20-ft. draft, and was to be protected with extensive breakwaters. Investigations were also made of ways to improve navigation on the Niger within Nigeria.

River Fauna and Economic Aspects.—Fishing is everywhere important to the riverine communities and from the middle Niger alone (the main market is at Dioro) about 20,000 tons per annum of smoked and dried fish is sent off to markets as far as Ghana. The river fauna is rich and diverse, the largest species represented being the hippopotamus and the crocodile, and the manatee also occurs. Large numbers of crocodiles are killed and their skins exported. The Niger perch and the tiger fish are the two best-known fish. The former is found in many other African rivers; *e.g.*, the Nile, where it is known as the Nile perch. In the Niger the largest specimens of perch caught have been just under 200 lb.; tiger fish generally weigh less than 20 lb. In the Republic of Mali much of the crop cultivation is dependent on irrigation from the Niger and its tributaries. Population is frequently concentrated near the river, especially for some distance downstream from Tombouctou where the desert reaches the left bank.

After 1940 the French worked to control the water in the "inland delta" with both large and small projects. The main works are a large barrage at Sansanding and a smaller one at Sotuba, together with the building of irrigation canals and leveling of the land. The Sansanding barrage was begun in 1934 and completed in 1946; it is half a mile long with 500 sluice gates, and has a road across the top and a navigation canal leading round the dam. Irrigation water from these works has brought under cultivation land which was previously waste or poor seasonal pasture. Settlers have had to be attracted into these new areas and assisted to establish themselves; 100,000 ac. are under cultivation. It was intended originally to grow cotton on the irrigated land but, compared with the Nile valley, the soils are not rich enough and the annual deposit of silt is not as much. Rice is the main crop and occupies 60% of the cultivated area. There have been some experiments with mechanical cultivation. The reduction in the flow of the river has had some effect on the problem of sand accumulation farther downstream, and there has also been some conflict of interests between the new cultivators and pastoralists who have traditionally used the land for seasonal grazing. The pastoralists are now restricted in their movements by canals and cropland. Throughout much of its length the Niger valley attracts herdsmen seeking pasture and water for their flocks and herds during the dry season. In Nigeria there are many parts of the valley which are considered to be potential rice-growing areas provided that some means can be found for controlling floodwater. By mid-1960s work was in progress on a dam at Kainji (some distance upstream from Jebba) to control the river flow for the production of hydroelectric power, to improve navigation, to create a major fishing reservoir and to make agricultural development possible in the valley below Jebba. The delta area has been explored for oil for many years and there are several wells in production, the oil being exported via Port Harcourt.

Exploration.—The Niger is almost certainly the great eastward-flowing river reached by the young Nasamonians who had crossed the Sahara and whose journey is recorded by Herodotus. Vague references to a great river in west Africa are made in the writings of Pliny and Ptolemy. During the middle ages contradictory opinions were held as to the source, course and outlet of this river. Idrisi, the 12th-century Arab scholar, maintained that there was a common source for the Nile and the "Nile of the Negroes" (the Niger) in the Mountains of the Moon, and it is probable that he thought of the Shari (Chari), Lake Chad, Benue, Niger and Senegal as one great river flowing to the west into the Atlantic. This opinion was held by Henry the Navigator and when the Portuguese seamen discovered the mouth of the Senegal in 1445 they thought they had found its outlet. When it was proved that the Senegal was independent, there was a return to the idea of an eastward-flowing river which emptied itself into the Nile. In the 15th century Ibn Batutah, the Muslim traveler, was acquainted with the middle course of the Niger, from above Tombouctou to Gao. The great Arab traveler, Leo Africanus, who probably visited the western Sudan in 1513–15 and sailed on the Niger, for an unknown reason stated that it flowed westward and thus it was shown on maps of the 16th, 17th and 18th centuries. For much of this time access to the western Sudan from the north by way of the Sahara was impossible for Europeans because of the closing of the north African coast by Moorish pirates. European traders on the coast of the Gulf of Guinea were either not interested or were unable to penetrate inland from the south.

That the outlet of the great river was in the Gulf of Guinea, in the delta which was already known, does not seem to have been suspected until the end of the 18th century. In 1788 the African association was founded in London to promote discovery and trade and to attempt to determine the course of the Niger. Several unsuccessful attempts were made to penetrate the western Sudan from the north. Frederick Hornemann, the German explorer, undoubtedly reached the Niger about 1800, somewhere in central Nigeria, but he did not return to tell of his discoveries. In 1795–97 the Scotsman, Mungo Park, traveled inland from the Gambia to reach the Niger at Ségou, and to find it "glittering to the morn-

ing sun, as broad as the Thames at Westminster, and flowing slowly to the eastward." This established the direction of the river's flow. Park went downstream some distance and then up to Bamako before returning to the coast. In 1805 after an arduous journey he was back at Bamako to commence the great journey downstream which ended tragically with his drowning in the rapids, probably at Bussa. No record remained of this journey and so this great section of the Niger was still unknown in Europe. Park had believed that the Niger flowed to join the Congo; others, among them James Rennell, the English geographer, that it flowed into a great swamp, "the sink of North Africa." In 1802 a German, C. G. Reichard, suggested that it flowed into the Gulf of Guinea through the Rio Nun and he was supported in this opinion by an Englishman, James Macqueen. The explorations of A. G. Laing, W. Oudney, D. Denham, H. Clapperton, Richard L. Lander and R. A. Caillié in the 1820s further revealed the interior parts of west Africa. They contributed little to solving the problem of the Niger's termination, though Clapperton believed that it was in the Gulf of Guinea. Proof of this came in 1830 when Richard Lander, who had accompanied Clapperton in 1825–27, returned with his brother John and made the journey by canoe from Bussa to Brass at the mouth of the Niger delta. With this knowledge the river was used for voyages from the coast into the interior in the 1830s and 1840s, and in 1854 W. B. Baikie in the steamer "Pleiad" made extensive voyages on the Niger and the Benue. The middle section of the river, from Tombouctou to Say, was traveled by H. Barth during the course of his explorations, 1850–55. In the latter half of the 19th century the lower section of the river was used as a trade route by European companies of which the Royal Niger company (incorporated in 1886) was the most important. The company not only developed trade but also established British supremacy on this part of the river and laid the foundations for the administration of adjacent territories. In 1900 the British government assumed responsibility from the company and declared the Protectorate of Northern Nigeria.

In the western parts of the Niger basin the French advance from Senegal was initiated by L. L. C. Faidherbe. Ségou was reached in 1866 and forts established between the Senegal and the Niger between 1879 and 1881. A railway was begun in the following year and reached Kulikoro in 1904 to link the Niger with the upper limits of navigation on the Senegal. The through line from Dakar to Bamako was not completed until 20 years later. In 1883 the French launched a gunboat, the "Niger," on the upper reaches of the river and this made the voyage downstream to Tombouctou in 1887. Nine years later M. Hourst navigated the river from Tombouctou to its mouth. In the late 19th century and early 20th century the Niger basin away from the river was explored—particularly by the German, G. A. Krause (1886–87), from the Gold Coast and by the Frenchman, L. G. Binger (1887–89), from Senegal through to the Ivory Coast. These journeys revealed the considerable size of rivers (*e.g.*, the Volta and its tributaries) that were independent of the Niger system and flowed directly southward to the Gulf of Guinea. Though the upper reaches of the Niger and the Senegal in the west and the lower Niger in the east were of great importance for the French and British respectively in establishing their influence in west Africa, the Niger never fulfilled the expectations of some of its earlier explorers, as it proved to be unsuitable for uninterrupted navigation.

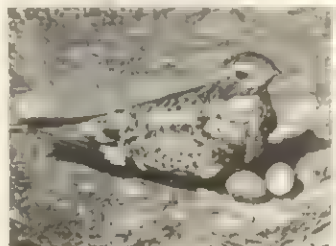
NIGGLI, PAUL (1888–1953), Swiss mineralogist whose *Lehrbuch der Mineralogie* (two volumes; 1924–26) set a new standard of achievement and provided a new vista of the content of modern mineralogy, was born at Zofingen, Aargau canton, on June 26, 1888. He graduated as an engineer at the Zürich technical high school but turned immediately to the field of mineralogy and petrology. His early researches dealt with the chloritoid schists of the northeast edge of the Gotthard massif, and were pioneer studies applying physicochemical principles to the subject of stress metamorphism. He moved to a chair at Leipzig university (1915) and later at Tübingen (1918). This period saw the production of his *Geometrische Kristallographie des Diskontinuums* (1919), which provided the idea of a systematic deduction of the space group by means of X-ray data and supplied a complete outline of methods that have since been used for the determination of space groups. He succeeded to the chair of mineralogy and petrology at the University of Zürich in 1920. He served as rector of the Federal Institute of Technology in Zürich (1929–32) and of the University of Zürich (1940–42). Niggli died in Zürich on Jan. 13, 1953.

In the field of igneous petrology, Niggli was active in the study of petrographic provinces and he published, with Conrad Burri, *Die jungen Eruptivgesteine des mediterranen Orogens*, two volumes (1945–49). Niggli's contributions to Swiss mineralogy are contained in the two-volume *Die Mineralien der Schweizeralpen* (1940), written in collaboration with others. Other publications include *Das Magma und seine Produkte* (1937), *Gesteine und Minerallagerstätten* (1948) and *Die kristallinen Schiefer*, revised edition, volume 1 (1924), with U. Grubenmann. (C. E. T.)

NIGHT BLINDNESS: *see* VISION: *Dark Adaptation and Rhodopsin, the Rod Pigment.*

NIGHTHAWK, a name applied to certain American birds of the genus *Chordeiles*. Unrelated to true hawks, they belong to the nightjar or goatsucker family (Caprimulgidae). Nighthawks live on insects caught, as the bird flies about, in the open capacious, whisker-bordered mouth. The common nighthawk (*C. minor*) inhabits most of North America, migrating south in winter. Less exclusively nocturnal than other nightjars, it often flies about and migrates all day. Two protectively coloured eggs are laid among gravel or on flat gravel roofs. In courtship the nighthawk plunges toward the earth and pulls out of the dive with a loud "zoom" of air through its quills It also utters a nasal *peent* repeated in flight. *See* also NIGHTJAR. (DN. A.)



PATRICIA WITHERSPOON FROM NATIONAL AUDUBON SOCIETY

COMMON NIGHTHAWK (CHORDEILES MINOR)

NIGHTINGALE, FLORENCE (1820–1910), English nurse, generally accepted as the originator and founder of modern nursing, whose achievements in public health were almost equally important, was born in Florence, Italy, on May 12, 1820, the second daughter of wealthy and cultured parents. Her socially ambitious mother intended that she should make a brilliant marriage, but such ambitions were vain. In 1837, at the age of 17, Miss Nightingale heard, as Joan of Arc had heard, the voice of God calling her to service. A period of perplexity followed as to the form of service she was to undertake, but by 1844 her vocation had become clear: she was to nurse the sick.

A desperate struggle with her family ensued. Nursing at that time was disreputable, and nurses frequently were drunken prostitutes. In spite of the furious opposition she met, Miss Nightingale would not be turned from her determination. When Richard Monckton Milnes, later Lord Houghton, repeatedly pressed her to marry him, she refused, even though he was "the man I adore." Everything had to be sacrificed to her vocation. Years passed in misery and frustration, and it was not until 1851 that she was allowed to gain her first nursing experience, with the Protestant deaconesses at Kaiserswerth in Germany, and not until 1853 that she left home to take her first post, the reorganization of a small hospital in Harley street, London, the Institution for the Care of Sick Gentlewomen in Distressed Circumstances.

The reorganization was a brilliant success, and it was her work in Harley street that led Sidney Herbert, secretary of war in the British cabinet, to invite her to undertake a mission to the Crimea. War with Russia had been declared in March 1854; by October England was ringing with the horrible state of the British military hospitals revealed by the special correspondent of the *Times* (London). Florence Nightingale sailed for the Crimea with 38 nurses

on Oct. 21, 1854, and within a month found that she had more than 5,000 men in her charge. The so-called hospitals were vast dilapidated buildings, filthy, bare, not merely lacking medical equipment but destitute of every convenience for common decency. By superhuman efforts she brought order out of chaos, working day and night, often on her feet for 20 hours at a stretch and hindered at every turn by official jealousy and intrigue. Every night she made a personal inspection of the vast wards. But she did more than make the hospitals sanitary; she revolutionized the treatment of the private soldier, and the army regarded her with something approaching worship.

When the story of her achievements reached home, a great outburst of enthusiasm made her a national heroine, and £45,000 was raised by public subscription as a testimonial and placed at her disposal. But when she returned from the Crimea she insisted on going into retirement. She had dedicated her life to the welfare of the private soldier, and she believed that her popularity would prejudice the government against her. She retired so completely that when in 1907 she was awarded the Order of Merit the announcement came as a surprise; most people thought she had died half a century before.

In fact, however, with Sidney Herbert's help, she had embarked on a movement for army reform, and in 1857, encouraged by Queen Victoria, she obtained a commission to inquire into the sanitary condition of the army. For the first time in history the food, housing and health of the soldier in peacetime were scientifically examined. In 1858 she published an immense volume, *Notes on Matters Affecting the Health, Efficiency and Hospital Administration of the British Army.* In 1859 a commission was set up to inquire into the sanitary condition of the army in India, and in 1863 its report was submitted to Miss Nightingale. Work for the army had become only a part of her activities. Military hospitals had led her to civil hospitals, military nursing to civil nursing, military health to public health. In July 1860, with the sum subscribed as a testimonial, she opened the Nightingale training school for nurses at St. Thomas' hospital. From that date modern nursing may be said to begin. Every probationer entering the school was interviewed by Miss Nightingale and remained under her close supervision. The strain of this, however, was too great, and her health, shaken by her enormous exertions in the Crimea, gave way. Though an invalid, she continued to work, nevertheless, and became a ruthless taskmaster to others. The war office leaned on her advice, all sanitary papers were sent to her, she drew up regulations, framed warrants, reported on barrack plans. She was an acknowledged authority on India, though she had never been there, and viceroy after viceroy came to her for his "Indian education." As the years went by thousands of nurses came under her control, after 1862 district nursing was developed under her guidance; the work involved in that alone would have occupied the whole time of an ordinary woman. Not until 1872, when she "went out of office," did the fury of her work slacken. Then she became interested in mysticism, assisted Benjamin Jowett in the translation of the dialogues of Plato and compiled a book of extracts from the Christian mystics. Personal relationships, especially with young people, became of increasing importance, and she enjoyed a tranquil old age, darkened only by the gradual loss of her sight. She died on Aug. 13, 1910. By her express wish the offer of a national funeral and burial in Westminster abbey was refused, and her coffin was carried to the family grave in the little country churchyard of East Wellow, Hampshire, by six sergeants of the British army.

BIBLIOGRAPHY.—Sir E. Cook, *Life of Florence Nightingale*, 2 vol. (1913), which contains a bibliography of Miss Nightingale's writings; Lytton Strachey, essay in *Eminent Victorians* (1918); I. B. O'Malley, *Life of Florence Nightingale, 1820–1856; a Study of Her Life Down to the End of the Crimean War* (1931); Cecil Woodham-Smith, *Florence Nightingale, 1820–1910* (1950).
(C. W.-SH.; X.)

NIGHTINGALE, the bird celebrated beyond all others for the vocal powers that, contrary to usual belief, it exercises at all hours of the day and night, during several weeks after its return from its winter quarters in the south. The song itself is indescribable, being variations on a complex plaintive air, though many attempts, from the time of Aristophanes to the present, have been made to express in syllables the sound of its many notes. Poets have descanted on the bird (which they nearly always make of the feminine gender) leaning its breast against a thorn and pouring forth its melody in anguish. But the cock alone sings, and there is no reason to suppose that the cause and intent of its song differ in any respect from those of other birds' songs (*see* SONGBIRD).

ERIC HOSKING
EUROPEAN NIGHTINGALE (LUSCINIA MEGARHYNCHOS)

In contrast with the nightingale's voice is the inconspicuous coloration of the bird's plumage, which in both sexes is of a reddish brown above and dull grayish white beneath, the breast being rather darker and the rufous tail showing the only bright tint.

No nightingale (genus *Luscinia*) is found in America, but it is closely related to the American thrush (*q.v.*) and a member of the same family, the Turdidae. The European nightingale (*Luscinia megarhynchos*) is abundant as a summer visitor, breeding in suitable localities in southern England and in Wales. On the continent of Europe it does not occur north of a line stretching irregularly from Copenhagen to the northern Urals. Over south Europe otherwise it is abundant. The nightingale reaches Iran, and is a winter visitor to the Arabian peninsula and Africa. The larger eastern *L. philomela*, russet brown in both sexes, is a native of eastern Europe. *L. hafizi* of Iran is probably the Perso-Arabic bulbul of poets.

The nightingale reaches its English home about the middle of April, the males (as is usual among migratory birds) arriving several days before the females. On the cocks being joined by their partners, the work for which the long and hazardous journey of both was undertaken is speedily begun, and before long the nest is completed. This is of a rather uncommon kind, being placed on or near the ground, the outworks consisting chiefly of a great number of dead leaves ingeniously applied together so that the plane of each is mostly vertical.

In the midst of the mass is wrought a deep cuplike hollow, neatly lined with fibrous roots, but the whole is so loosely constructed, and depends for lateral support so much on the stems of the plants among which it is generally built, that a slight touch disturbs its beautiful arrangement.

In this nest four to six eggs of a deep olive colour are laid and the young subsequently hatched. The nestling plumage of the nightingale differs much from that of the adult, the feathers above being tipped with a buff spot, just as in the young of the European robin, hedge sparrow and redstart, thereby showing the natural affinity of all these forms. Toward the end of summer the nightingale migrates to its African winter haunts.

The name nightingale has been applied to several other birds. The so-called Virginian nightingale is a species of grosbeak; the Pekin nightingale or Japanese nightingale is a small babbler (*Liothrix luteus*) of the Himalayas and China, found also in Hawaii.

NIGHTJAR (GOATSUCKER), *Caprimulgus europaeus*, a bird erroneously believed since very ancient days to have the habit implied by its second name. The family to which it belongs (Caprimulgidae) is almost cosmopolitan, but is not represented in New Zealand and Polynesia. The nightjar is characterized by its flat head, wide mouth fringed with bristles, large eyes and soft plumage which results in noiseless flight. It arrives in Europe from Africa late in the spring, returning in the early autumn. Its food consists of insects, chiefly moths and cockchafers, which it catches on the wing at night.

When resting the nightjar usually sits parallel to the length of a bough. In this position the cock bird utters his curious loud burring song. The two eggs are laid on the ground; the young are clad in dark-spotted down, rendering them, like their parents, exceedingly difficult to see when they crouch on the ground.

The red-necked nightjar (*C. ruficollis*) is very similar to the

common nightjar in appearance but has a reddish-buff collar and white throat patch and is somewhat larger. It occurs in Spain and Portugal. The Egyptian nightjar (*C. aegyptius*) closely resembles the common nightjar. Others are found throughout the old world.

In America their place is taken by the allied species, *Caprimulgus vociferus*, the whippoorwill (*q.v.*). The nighthawk (*q.v.*) is another common American species, with a voice quite different from that of the whippoorwill.

ERIC HOSKING

EUROPEAN NIGHTJAR (CAPRIMULGUS EUROPAEUS)

NIGHT SCHOOL or EVENING SCHOOL, a form of continuing education usually conducted by the public schools for older adolescents and adults through evening classes and other educational activities offered outside of regular working hours. Night schools, especially in industrial cities, often stress vocational education (*q.v.*) and offer cultural and recreational programs as well as general education. In the early 20th century in the United States and Canada many night schools provided courses in English for new immigrants and in Canada such courses were again in demand after World War II. (*See* also AMERICANIZATION.) Communist countries, especially the U.S.S.R. and Communist China, have used night schools extensively. *See* ADULT EDUCATION.

NIGHTSHADE, a general term for plants of the genus *Solanum*, of the nightshade family (Solanaceae), and to certain similar plants in the Solanaceae and other families. The species to which the name of nightshade is commonly restricted in North America and England is *Solanum dulcamara*, also called bittersweet or woody nightshade. It is a native of Europe, north Africa and temperate Asia and is widely naturalized, being a common plant in damp hedgebanks and thickets, scrambling over underwood and hedges, all over eastern and central North America and throughout England.

It has slender, slightly woody stems, with alternate lanceolate leaves, more or less heart shaped, with two leafy lobes at the base. The flowers are arranged in drooping clusters and resemble those of the potato (to which it is related) in shape, although they are much smaller. The flower clusters spring from the stems at the side of, or opposite to, the insertion of a leaf. The corolla is wheel shaped, of a lilac-blue colour with a green, or sometimes white, spot at the base of each segment, and bears the yellow stalkless anthers united at their margins so as to form a cone in the centre of the flower.

JOHN MARKHAM

FRUITING BRANCH OF DEADLY NIGHTSHADE (ATROPA BELLADONNA)

The flowers are succeeded by egg-shaped scarlet berries, one-half inch long. Both the berries and the foliage are poisonous, due to the presence of solanine, sometimes causing convulsions and death if ingested in large doses. The plant derives its names of bittersweet (not to be confused with false or climbing bittersweet [*q.v.*] or waxwork, *Celastrus scandens*, highly prized for its decorative coloured fruit) and dulcamara from the fact that its taste is at first bitter and then sweet.

The black nightshade (*S. nigrum*), also poisonous, differs from the common nightshade in having white flowers in small umbels and globose black berries. It is a common and almost cosmopolitan weed in gardens and waste places, growing about 12 or 15 in. high, and has ovate leaves with the edge entire, sinuate or toothed. The plant is common in eastern North America. From the black nightshade have been derived the garden huckleberry (*S. intrusum*) and the wonderberry (*S. burbanki*), both with edible fruit.

Deadly nightshade or dwale is the belladonna (*Atropa belladonna*), a tall bushy herb of the same plant family and the source of several alkaloid drugs.

The name enchanter's nightshade is applied to weak-stemmed plants of the genus *Circaea*, of the evening primrose family (*see* ONAGRACEAE). Malabar nightshade refers to twining herbaceous vines of the genus *Basella*.

See also SOLANACEAE. (N. TR.; X.)

NIHILISM is a philosophy of skepticism that originated in 19th-century Russia during the early years of the reign of Alexander II and was most clearly expressed in the literary criticism of Dmitri Pisarev. The term (from the Latin *nihil*, "nothing") was first used by Nikolai I Nadezhdin in an article in the *Messenger of Europe*, and it later was popularized by Ivan Turgenev in his celebrated novel *Fathers and Sons* (1862).

The philosophy of nihilism has often been associated erroneously with regicide and the policy of terror employed by a clandestine political organization against the imperial administration. Fundamentally nihilism represented a philosophy of negation of all forms of aestheticism; it advocated utilitarianism and scientific rationalism. The social sciences and classical philosophical systems were rejected entirely. Nihilism represented a crude form of positivism and materialism, a revolt against the established social order; it negated all authority exercised by the state, by the church or by the family. It based its belief on nothing but scientific truth; science became the cure-all for social problems. All evils, nihilists believed, derived from a single source, ignorance, which science alone would overcome. Prince Peter Kropotkin, the leading Russian anarchist, defined nihilism as a struggle against all forms of tyranny, hypocrisy and artificiality in favour of individual freedom. It was a revolt of an adolescent generation that cherished infinite faith in scientific truth.

The thinking of nihilists was profoundly influenced by such men as Ludwig Feuerbach, Charles Darwin, Henry Buckle and Herbert Spencer. Since nihilism denied the duality of man as a combination of body and soul, of spiritual and material substance, it came into violent conflict with ecclesiastical authorities. Since nihilists questioned the validity of the divine right doctrine, they came into similar conflict with secular authorities. Since they scorned all social bonds and family authority, the conflict between fathers and sons was equally immanent, and it is this theme that is best reflected in Turgenev's novel. A comparison between Turgenev's hero, Bazarov, and Leonid Andreyev's Savva, created during the early 20th century, reveals the deterioration of nihilist philosophy, which changed from a faith in science into a justification of destruction. (A. G. M.)

NIHONGI, also known as *Nihon-shoki*, both of which terms mean literally "Written Chronicles of Japan," was compiled in A.D. 720 under imperial proposal and consists of 30 volumes, all written in Chinese. This compilation contains traditional myths, legends and historical records of several of the politically powerful clans as well as those of the imperial family. Chinese and Korean materials were also collected, amplified and reclassified according to the ancient history of Japan. The *Nihongi* includes, therefore, an abundant amount of material concerning Japan's historical period.

The other comparable ancient work, the *Kojiki* (*q.v.*), deals primarily with the divine and prehistoric ages. The *Nihongi* continues the story of the mythical origins down to A.D. 697, just before the Nara period. It describes the impact of early Chinese civilization, the introduction of Buddhism and the Taika reforms, the latter being strongly influenced by the Sui and T'ang dynasties. The *Nihongi* is the first of six officially compiled chronicles (*Rikkoku-shi*) which continued to A.D. 887 by imperial command. The *Nihongi* was read ceremonially before the emperor at the imperial court during the Heian period and fragments survive of the anno-

tations of some of the government scholars of that time. The first printing of the part entitled "Divine Age" appeared in 1599; the most complete commentary, *Nihon-shoki-tsūshaku*, was published in 1899 by Iida Takesato. The English translation of the *Nihongi* was completed by William G. Aston in London in 1896.

See also JAPANESE MYTHOLOGY. (I. H.)

NIIGATA, a *ken* (prefecture) on the Sea of Japan coast of central Honshu, Jap. It includes the offshore islands of Sado and Ao. Area 4,855 sq.mi., pop. (1960) 2,442,037. Combined deposition of the Shinano and Aka rivers in the central part of the long coastline has created Niigata's key lowland, the Echigo plain. The rest of the prefecture is mountainous except for small southern coastal plains and lowlands along river courses. Niigata is Japan's largest rice producer and normally has the largest rice surpluses for shipment to city markets. Bad drainage and heavy winter snow cover prohibit winter cropping in most areas. Coastal fishing is practised. Cheap and plentiful hydroelectric power generated in the interior mountains has stimulated industrial growth (especially chemicals, metals and machinery) since 1940 in such cities as Niigata, Kashiwazaki, Naoetsu, Sanjō and Takada. Niigata produces large amounts of petroleum (Nagaoka and Kashiwazaki) and natural gas.

NIIGATA CITY, the prefectural capital and largest city (pop. [1960] 314,528), is located on the sea edge of the Echigo plain at the mouth of the Shinano river. It was an important rice port in feudal times and has continued as the leading Sea of Japan port in spite of silting, strong winds and stormy winters. Coal and raw materials imports predominate. In addition to its port, general commercial and administrative functions, Niigata is a growing industrial city (chemicals, cotton textiles, metals, machinery, paper and shipbuilding). Excellent local deposits of natural gas and available hydroelectricity have attracted many large factories. An earthquake, Japan's most severe since 1923, struck the city and surrounding area in June 1964, causing loss of life, many injuries and extensive property damage. (J. D. EE.)

NIJHOFF, MARTINUS (1894–1953), Dutch poet and critic whose work had great influence on modern Dutch poetry, was born April 20, 1894, at The Hague. He studied law at Amsterdam and literature at Utrecht, and was for many years editor of the long-established literary periodical, *De Gids*. He died at The Hague, Jan. 26, 1953.

Nijhoff began his literary career with *De Wandelaar* (1916), a collection of symbolical poems expressing an essentially modern anguish and despair in traditional poetic forms. It was followed by *Pierrot aan de lantaren* (1919), a poetic dialogue between Harlequin and Pierrot. His best-known collection, *Vormen*, appeared in 1924. He returned to more serious themes in *Nieuwe Gedichten* (1934) and *Het uur U* (1941). In Nijhoff's poetry simple everyday words are charged with power, and this makes his work almost untranslatable. In his prose sketch, *De pen op papier* (1927), he deals playfully with the process of poetic creation. He also wrote plays—*De Vliegende Hollander* ("The Flying Dutchman") (1930), written for an open-air performance by undergraduates, and a biblical trilogy, *Het heilige hout* (1950)—and translated both classical and modern works.

See T. de Vries, *M. Nijhoff, wandelaar in de Werkelijkheid* (1946). (GD. W. HS.)

NIJINSKY, VASLAV (WASLAW) (1890–1950), Russian dancer, whose remarkable performances with the Diaghilev ballet brought him an almost legendary fame. Born in Kiev, Feb. 28, 1890, Nijinsky studied under Legat and Oboukhov in the Russian Imperial Ballet school, St. Petersburg, graduating in 1908. Almost immediately, Sergei Diaghilev selected him as leading dancer of the company he presented in Paris in 1909. Diaghilev deeply influenced Nijinsky's entire career. Endowed with phenomenal technique and a genius for characterization, Nijinsky scored triumphs in *Petrouchka*, *Carnaval*, *Scheherazade* and *Le Spectre de la Rose*, all of which were created by Michel Fokine. A daringly original choreographer, Nijinsky created *L'Aprés-midi d'un Faune*, *Le Sacre du Printemps*, *Jeux* and *Till Eulenspiegel* (the latter produced in America without Diaghilev's personal supervision), all for the Diaghilev ballet. In 1913 Nijinsky married Romola de Pulzky. His brief career was terminated in 1917 by the threat of insanity, which shadowed the rest of his life. He died in London on April 8, 1950.

Nijinsky's sister, Bronislava Nijinska (1891–), became a distinguished choreographer.

See Romola Nijinsky, *Nijinsky* (1934). (LN. ME.)

NIJMEGEN (Ger. NIMWEGEN), the oldest town of the Netherlands and the largest in Gelderland province, extends along the Waal (southern arm of the Rhine) 10 mi. S.S.W. of Arnhem near the German border. Pop. (1960) 127,172. An important industrial centre (metal products, machinery, electrical and heating apparatus, paper, artificial fibres, soap, clothing and shoes are among its manufactures), it has excellent railway and inland water communications with western Europe.

Nijmegen, the Roman Noviomagus, like Rome, was built on seven hills rising from the riverside. It was a free imperial city and later a member of the Hanseatic league; in 1579 it joined the Utrecht Union and the peace treaty between Louis XIV, the Netherlands, Spain and the Holy Roman empire was signed there in 1678. Until 1874 it served mainly as a frontier fortress. The old town walls were demolished (1877–1884) and were replaced by a promenade and gardens. Subsequently a fine new town grew up on the south side. During World War II the town centre was badly damaged (it has since been rebuilt along contemporary lines), and later Nijmegen was the scene of a U.S. airborne landing.

A beautiful park, the Valkhof, contains some remains of Charlemagne's palace. This was destroyed by Norsemen but was rebuilt by Frederick Barbarossa in 1155 and was finally demolished (1796). Only two portions remain; the choir of the 12th-century palace-church and a 16-sided baptistery, probably constructed between 800 and 1400. Both these have been restored several times. Close-by is the lofty 17th-century watchtower of the Belvedere (now a restaurant). The fine Renaissance Grote Kerk of St. Stephen, enlarged in the 15th and 16th centuries, was severely damaged in 1944; partly rebuilt, its renovated tower is again one of the town's most striking features. The Renaissance Raadhuis or town hall also sustained war damage but has been splendidly restored; a collection of 17th-century Gobelins forms the *pièce de résistance* of its art collection. Other notable buildings include Latijnse school (1544–45), the Laekenhal (Cloth hall, now a restaurant), the Waag or Weighhouse (1612), the chapel of the old cloister Marienburg (now the municipal museum), the restored 16th-century Besienderhuys, the Brewershouse, the Protestant Children's orphanage and the modern church of St. Peter Canisius (1960). The Rijksmuseum Kam houses an important collection of Roman antiquities.

Nijmegen is the seat of a Roman Catholic university (founded 1923) with an important medical faculty and hospital.

NIJMEGEN, TREATIES OF (1678, 1679), the treaties of peace terminating the great war that Louis XIV of France had begun in 1672 (*see* DUTCH WARS). Negotiations having begun in 1676, the first treaty was concluded between France and the estates-general of the United Provinces of the Netherlands on Aug. 10, 1678. France agreed to return Maastricht and to remove the protectionist discrimination against the Dutch contained in J. B. Colbert's tariff of 1667. This was dependent on the second agreement, which was concluded between France and Spain on Sept. 17, 1678, by which Spain renounced Franche-Comté and agreed to frontier changes in Flanders, Hainaut and Artois. The peace represented a defeat for the French attempt to subdue the United Provinces politically and commercially, but was otherwise a substantial achievement: Louis XIV had withstood a powerful coalition and obtained important concessions from Spain. The estates-general made peace against the advice of William III of Orange, stadholder of Holland, who saw the European as well as the Dutch interest, and without the agreement of the Holy Roman emperor Leopold I, who continued fighting for some months longer. At length Leopold too accepted French terms, by the treaty of Feb. 5, 1679, keeping Philippsburg (which his forces had taken) but renouncing Freiburg im Breisgau and granting free access to it from Breisach (French since 1648). France also continued to occupy Lorraine, since the duke, Charles V, refused the conditions

imposed for his restoration. Two further treaties in 1679 terminated hostilities between France and Brandenburg (peace of St. Germain, June 29) and between France and Denmark (peace of Fontainebleau, Sept. 2). Brandenburg and Denmark restored to France's ally Sweden territories taken by them. (I. F. B.)

NIKE, the Greek goddess of victory (Lat., VICTORIA). She does not appear personified in Homer. In Hesiod she is the daughter of the giant Pallas and of the infernal river Styx, and is sent to fight on the side of Zeus against the Titans. Nike does not appear to have been the object originally of a separate cult at Athens. She was at first connected and confounded with Pallas Athena, the dispenser of victory, but gradually separated from her. As an attribute of both Athena and Zeus, Nike is represented in art as a small figure carried in the hand by those divinities. Athena Nike was always wingless, Nike alone winged. She also appears carrying a palm branch or a wreath (sometimes a Hermes staff as

BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM

NIKE, FROM A BRONZE VESSEL, PROBABLY MADE IN A GREEK CITY OF SOUTHERN ITALY, ABOUT 490 B.C.

the messenger of victory), erecting a trophy or recording a victory on a shield, or, frequently, hovering with outspread wings over the victor in a competition; for her functions referred to success not only in war but in all other undertakings. In fact, Nike gradually came to be recognized as a sort of mediator of success between gods and men.

At Rome, Victoria was worshiped from the earliest times. The legendary Evander was said to have erected a temple in her honour on the Palatine before the foundation of Rome itself. She was identified with the obscure Sabine goddess Vica Pota and others. Special games were held in her honour in the circus, and generals erected statues of her after a successful campaign. She came to be regarded as the protecting goddess of the senate, and her statue in the Curia Julia (originally brought from Tarentum and set up by Augustus in memory of the battle of Actium) was the cause of the final combat between Christianity and paganism toward the end of the 4th century.

Victoria had altars in military camps, a special set of worshipers and colleges, a festival on Nov. 1, temples at Rome and throughout the empire. Representations of Nike-Victoria are numerous.

NIKISCH, ARTHUR (1855–1922), Austro-Hungarian conductor who followed the tradition of Hans von Bülow. Born at Lebenyi Szant Miklos on Oct. 12, 1855, he studied in Vienna from 1866 to 1873 under J. Hellemesberger, W. Schenner and F. O. Dessoff. In 1878 he was appointed coach at the Leipzig opera and in the following year he became principal conductor there. He was conductor of the Boston Symphony orchestra (1889–93) and of the Gewandhaus orchestra at Leipzig from 1895 until his death there (Jan. 23, 1922). During this time he was also conductor of the Berlin Philharmonic orchestra, with which he toured widely. In 1897 he succeeded von Bülow as conductor of the Philharmonic concerts at Hamburg. He toured the U.S. with the London Symphony orchestra in 1912 and conducted the *Ring* at Covent Garden in 1913. He excelled in performances of Wagner. His style was marked by intensity of romantic expression and his technique by severe precision and economy of gesture. As an accompanist at the piano he appeared in recitals with his pupil Elena Gerhardt, the *Lieder* singer.

See F. Pfohl, *Arthur Nikisch* (1925).

NIKKŌ, a small town in Tochigi prefecture, one of the chief centres of pilgrimage and sightseeing in Japan, lies in the Kwanto region of Honshu about 90 mi. (145 km.) N. of Tokyo, at the edge of Nikkō National park. Pop. (1960) 33,348. A Shintō shrine seems to have existed at Nikkō as early as the 4th century A.D., and in 767 a Buddhist temple was founded there by Shōdō Shōnin. Since the 17th century, however, Nikkō has been dominated by the great Tōshōgu shrine dedicated to the first of the Tokugawa shoguns, Tokugawa Ieyasu, who was buried there in 1617, and the Daiyuin mausoleum dedicated to his grandson Iemitsu (Iyemitsu), the third Tokugawa shogun, who died in 1651. The shrines and associated buildings are notable for their gorgeous colour and detail, but are thought by some to be overdecorated and often weak in design. Their magnificent setting, especially the grove of giant Japanese cedars in which they stand, greatly enhances the attractiveness of Nikkō. There are scores of hot mineral springs in the scenic Nasu volcanic area of the national park which also includes mountain peaks, waterfalls and lakes. The Nikkō Botanical garden of alpine flora is maintained by Tokyo university. (R. M.)

NIKOLAYEV, an *oblast* of the Ukrainian Soviet Socialist Republic, U.S.S.R., formed in 1937, covers an area of 9,614 sq.mi. Pop. (1959) 1,013,839. The *oblast* lies on the Black sea plain (Prichernomorskaya Nizmennost), which slopes down gently from the Dnieper uplands in the extreme north to the Black sea coast. The northern part is very much cut up by gullies, and soil erosion generally is severe. The Southern Bug river crosses the *oblast* and enters the sea by a long, winding estuary. There is little other surface water and even the larger rivers, such as the Gniloi Yelanets and Ingul, nearly dry out in summer. The coast has many lagoons and drowned valleys, often sealed off by sandbars. The whole area is steppe, with chernozem soils developed on loess, and a high proportion is plowed up for winter wheat, maize (corn), sunflowers and sugar beet. Vineyards and gardens are widespread, especially on the left bank of the Bug. Cattle and sheep are kept in large numbers. Only 400,310 (39%) of the people are urban. Apart from the administrative centre of Nikolayev, the 4 towns and .. urban districts are all small. Industry is chiefly concerned with processing agricultural products. In the north much granite is quarried. (R. A. F.)

NIKOLAYEV, a town and administrative centre of an *oblast* in the Ukrainian Soviet Socialist Republic, U.S.S.R., stands on the left bank of the estuary of the Southern Bug, at the Ingul outfall, about 40 mi. from the Black sea and 65 mi. from Odessa. Pop. (1959) 226,207. It was founded, near the site of the ancient Greek Olbia, in 1788 as a naval base, after the Russian annexation of the Black sea coast. In the 1870s a railway was built to the port. It is now one of the most important Soviet Black sea ports and a major shipbuilding centre specializing in tankers, trawlers, dredgers and diesel-propelled craft. Other engineering products include cement- and road-making machinery, equipment for metallurgical and coke-chemical factories, pumps, roller bearings and conveyer belts. There are also clothing, footwear and food industries. Nikolayev has shipbuilding and pedagogic institutes and an observatory. The port has rail links southeast to Kherson and the Crimea, northeast to Dnepropetrovsk and north to Kiev and central Russia. It was held (1941–43) by the Germans during World War II. (R. A. F.)

NIKOLAYEVSK-ON-AMUR, a town and port of Khabarovsk *krai* of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands at the head of the Amur estuary, on its northern bank. Pop. (1959) 30,923. Founded in 1850, it was for a few

years thereafter the main Russian settlement of the far east. It declined, however, and is now overshadowed by the new port and naval base of Sovetskaya Gavan, 300 mi. S., which has rail communication with the interior. Transshipment from seagoing to river craft takes place at Nikolayevsk and there are shipbuilding and repair yards. A fishing fleet is based there. Other industries include furniture, brick and confectionery making, and brewing. Iron ore is mined in the vicinity and sent to the steel mill at Komsomolsk-on-Amur. Nikolayevsk is the focus for local air services.

(R. A. F.)

NIKON (Nikita Minin) (1605–1681), Russian patriarch and the leader of a reform movement that caused the schism in the Russian Orthodox Church, was born in the village of Vel'demanovo in the province of Nizhni Novgorod (now Gorki), the son of a peasant of Finnic stock. After acquiring the rudiments of an education in a nearby monastery, Nikon married, entered the clergy and settled in Moscow; but the death of all three of his children caused him to seek repentance and solitude. For the next 12 years (1634–46) he lived as a monk, as a hermit and finally as an abbot in several northern localities. In 1646 he came on monastic business to Moscow, where he made so favourable an impression on the young tsar Alexis and on the patriarch Joseph that they appointed him archimandrite (abbot) of the Novospasski monastery in Moscow, the burial place of the Romanov family. During his stay there, Nikon became closely associated with the circle led by the tsar's confessor, Stefan Vonifatiev, and the priests Ivan Neronov and Avvakum Petrovich (all natives of the Nizhni Novgorod province), which strove to revitalize the church by bringing about closer contact with the mass of the faithful and to purify religious books and rituals from errors and Catholic accretions. With their help Nikon became first metropolitan of Novgorod (1648) and then patriarch of Moscow and all Russia (1652).

Nikon accepted the highest post in the Russian church only on condition that he should receive full authority in matters of dogma and ritual. In 1654, when the tsar departed for the campaign against Poland, he asked Nikon to supervise the country's administration as well as watch over the safety of the tsar's family; and in 1657, with the outbreak of the new war with Poland, he endowed him with full sovereign powers. Nikon, enjoying the friendship of the tsar, the backing of the reformers and the sympathy of the population of Moscow, stood at the pinnacle of his career.

It was not long, however, before Nikon alienated his friends and infuriated his opponents by his high-handed methods and brutal treatment of all those who disagreed with him. On assuming the patriarchate he consulted Greek scholars employed in Moscow and the books in the patriarchal library and concluded not only that many Russian books and practices were badly corrupted but also that the revisions which the circle of Vonifatiev had promulgated introduced new corruptions. He now undertook a thorough revision of Russian books and rituals in accord with their Greek models to bring about uniformity in the whole Orthodox Church. When his onetime friends rejected his reforms, Nikon had them exiled. Assisted by Greek and Kievan monks and supported by the Greek hierarchy, he now carried out several reforms of his own: he altered the form of bowing in the church, replaced the two-fingered manner of crossing with the three-fingered one and ordered that three alleluias be sung where tradition called for two. An ecclesiastical assembly that he convened in 1654 authorized him to proceed with the revision of liturgical books. He next began to remove from churches and homes icons that he considered incorrectly rendered. To quell mounting opposition to these moves he called in 1656 another assembly, which excommunicated those who failed to adopt the reforms.

Though all the changes introduced by Nikon affected only the outward forms of religion, some of which were not even very old, the population and much of the clergy resisted him from the beginning. The relatively uneducated clergy refused to relearn prayers and rituals, while the mass of the faithful was deeply troubled by Nikon's contempt for practices regarded as holy and necessary for Russia's salvation. This was the origin of the *Raskol* or great schism with the Russian Orthodox Church. Yet what really brought about Nikon's downfall was the hostility of the tsar's family and the powerful boyar families; they resented the autocratic manner in which he exercised authority in the tsar's absence and also objected to his claims that the church was superior to the state.

When Alexis returned to Moscow in 1658, relations between tsar and patriarch were no longer what they had been. Grown in self-confidence and incited by relatives and courtiers, Alexis ceased to consult the patriarch, though he avoided an open break with him. Nikon finally acted after several boyars had insulted him with impunity and the tsar failed to appear at two consecutive services at which Nikon officiated. On July 20 (new style; 10, old style), 1658, he announced his resignation to the startled congregation in the Church of the Assumption in the Kremlin; shortly afterward he retired to the Voskresenski monastery.

Nikon had apparently hoped in this manner to compel the tsar, whose piety was well known, to recall him and to restore his previous influence. This did not happen. After several months in self-imposed exile, Nikon began to regret his decision and attempted a reconciliation, but the tsar either refused to answer his letters or urged him to formalize his resignation. Nikon refused to do so on the ground that he had resigned merely from the Moscow see, not from the patriarchate as such. For eight years, during which Russia was effectively without a patriarch, Nikon stubbornly held on to his post, while Alexis, troubled by lack of clear precedent and by the fear of damnation, could not decide on a formal deposition. Finally, in Nov. 1666, Alexis convened a council attended by the patriarchs of Antioch and Alexandria to settle the dispute. The charges against Nikon were presented by the tsar himself. They concerned largely his behaviour in the period of the tsar's absence from Moscow, including his alleged arrogation of the title of "grand sovereign"; many of the charges were entirely without foundation. The Greek hierarchy now turned against Nikon and decided in favour of the monarchy. A Greek adventurer, Paisios Ligaridis (now known to have been in contact with Rome), was particularly active in bringing about Nikon's downfall. The council deprived Nikon of all his sacerdotal functions and on Dec. 23 (N.S.) exiled him as a monk to Beloozero. It retained, however, the reforms he had introduced and confirmed the excommunication of those who had opposed them and who were henceforth known as Old Ritualists (or Believers). In his last years Nikon's relations with Alexis improved. The succeeding tsar, Fedor III, recalled Nikon from exile; but Nikon died on Aug. 27 (N.S.), 1681, on the way back to Moscow.

Nikon was one of the outstanding leaders of the Russian Orthodox Church, an able administrator and firm in his principles. His ultimate failure was due to two main factors: (1) his effort to establish the hegemony of church over state had no precedent in Byzantine or Russian past and could not be enforced; and (2) he had an uncontrollable temper and an autocratic character that alienated all who were in contact with him and enabled his opponents first to disgrace and then to defeat him.

NIKOPOL, a town in Pleven *okrug* (district), northern Bulgaria, picturesquely situated on the bank of the Danube, east of the mouth of the Osum tributary, 23 mi. N.E. of Pleven city. Pop. (1963 est.) 5,817. It had in the past been confused with Nicopolis ad Istrum, founded by Trajan, but in 1871 the site of the latter was established as the village Nikyup on the Rositsa river about 50 mi. S.E. of Nikopol and the Roman town was largely uncovered by the 1960s. Nikopol was an important Danubian stronghold (ruined fortresses still dominate the town) founded by the Byzantine emperor Heraclius early in the 7th century. It was the scene of many battles. There in 1396 Sultan Bayazid I defeated a crusader's army led by King Sigismund of Hungary, an event that decided the fate of the Balkan peoples for centuries. During the Russo-Turkish Wars the Russians under Gen. N. P. Krudener stormed and captured the town (1877). Farming, viticulture and fishing are the main means of livelihood. (An. Be.)

NIKOPOL, a town in Dnepropetrovsk *oblast* of the Ukrainian Soviet Socialist Republic, U.S.S.R., stands on the northern shore of the Kakhovka reservoir (Kakhovskoye Vodokhranilishche) on the Dnieper, and on the Zaporozhe-Krivoi Rog railway 65 mi. S.S.W. of Dnepropetrovsk city. Pop. (1959) 82,992. Founded as Nikitin Rog in the 1630s at a strategic crossing of the river, it was renamed Nikopol in 1782. It is important as the centre of the world's largest deposit of manganese, first mined there in 1886. Reserves are estimated at more than 500,000,000 tons. The metallurgical industry produces steel tubes, cranes and agricultural machinery, and food processing and brewing are also important. A dam protects the lower part of the town. (R. A. F.)

NILE, an African river whose basin is the dominant feature of the northeastern quarter of the continent. Its length as the water flows from its most distant source to the entry of the Rosetta branch of the Nile delta into the Mediterranean is about 4,157 mi. This source is the head of the Luvironza in latitude 3° 40′ S. and about 30 mi. E. of Lake Tanganyika. The Nile is probably the longest river in the world. The Mississippi-Missouri was once taken to be the longest but the U.S. army engineers later gave the length from the most remote source of the Missouri to the sea as 3,860 mi. The Amazon also may be more than 4,000 mi. long, but its length is taken from maps on a scale of 1:1,000,000, while the Nile has been measured from maps on scales ranging from 1:100,000 to 1:250,000. More detailed maps of the Amazon on a larger scale would be likely to increase its estimated length because of the effect of sinuosity. The name Nile comes from the Greek Neilos (Latin Nilus), whose origin is unknown. Aiguptos in the Odyssey is the name of the Nile (masculine) as well as of the country of Egypt (feminine) through which it flows and survives both in the name Egypt and in the name Copt (*gupti* in the Arabic of upper Egypt). At the present time the Nile in Egypt and in the northern Sudan is called En Nil, El Bahr ("the river") or El Bahr en Nil (Nahr an Nil).

The basin covers approximately 1,100,000 sq.mi., or about one-tenth of the area of Africa. It embraces parts of Uganda, Kenya, Tanzania, Rwanda and Burundi, the Republic of the Congo, most of the Sudan, part of Ethiopia and the cultivated portion of Egypt (U.A.R.). It supports a rapidly increasing population, estimated at more than 50,000,000 in the mid-1960s, of whom about half live in Egypt. It is possible to travel by car in the dry season over most of the basin; but south of latitude 15° N. over the plains of the Sudan, motor transport is not usually possible from May to November. There are all-weather roads on the Lake plateau (around Lake Victoria in the Great Rift valley) and in the higher country leading to it and the Nile-Congo watershed.

Three principal streams form the Nile. The largest in volume is the Blue Nile (Al Bahr al Azraq, Sudan; Abay, Ethiopia), which draws practically all of its water from Ethiopia and contributes four-sevenths of the total supply of the main stream. Next comes the White Nile (Al Bahr al Abyad), which is the longest branch and supplies two-sevenths of the total; its headstreams flow into Lakes Victoria and Albert; and lower down in the Sudan it receives the Sobat, which obtains its water mainly from Ethiopia. The White Nile and Blue Nile join at Khartoum. Last there is the Atbara, draining the northwestern part of Ethiopia and joining the main stream 200 mi. N. of Khartoum, which contributes the remaining one-seventh. The Blue Nile and Atbara are both muddy rivers in flood time and bring down the soil that has made the cultivable land of Egypt and is still adding to it. From the Atbara junction over the great S-shaped bend to the Nile delta and to within a few miles of the Mediterranean there is not enough rain to produce any crops, and so this area depends entirely on irrigation by Nile water. The river is navigable from the sea to the high Aswan dam and then to Wadi Halfa (about 950 mi.), and the Aswan dam and the barrages are passed by locks. Between Halfa and Khartoum the river is broken up by the cataracts, and ordinarily navigation is possible only in short stretches. From Khartoum the White Nile is navigable for 1,104 mi. to Rejaf, 100 mi. from the Uganda border, the Jebel Aulia (Jabal al Awliya') dam, 25 mi. S. of Khartoum, being passed by a lock. From Rejaf to the Uganda border the river is again beset with rapids, but there is navigation from Nimule on the border into Lake Albert and up the Victoria Nile to the foot of the Murchison falls. Between Lakes Albert and Victoria there are two successions of rapids with a navigable stretch which includes Lake Kyoga (Kioga) between them. The Blue Nile is navigable during flood for 385 mi. as far as Roseires (Er Roseires; Ar Rusayris), though it is interrupted by the Sennar dam which has no lock. During the flood season the Sobat is navigable up to Gambela and the Bahr el Ghazal up to Wau (Waw). Regular air services operate on important routes throughout the Nile basin, including Ethiopia.

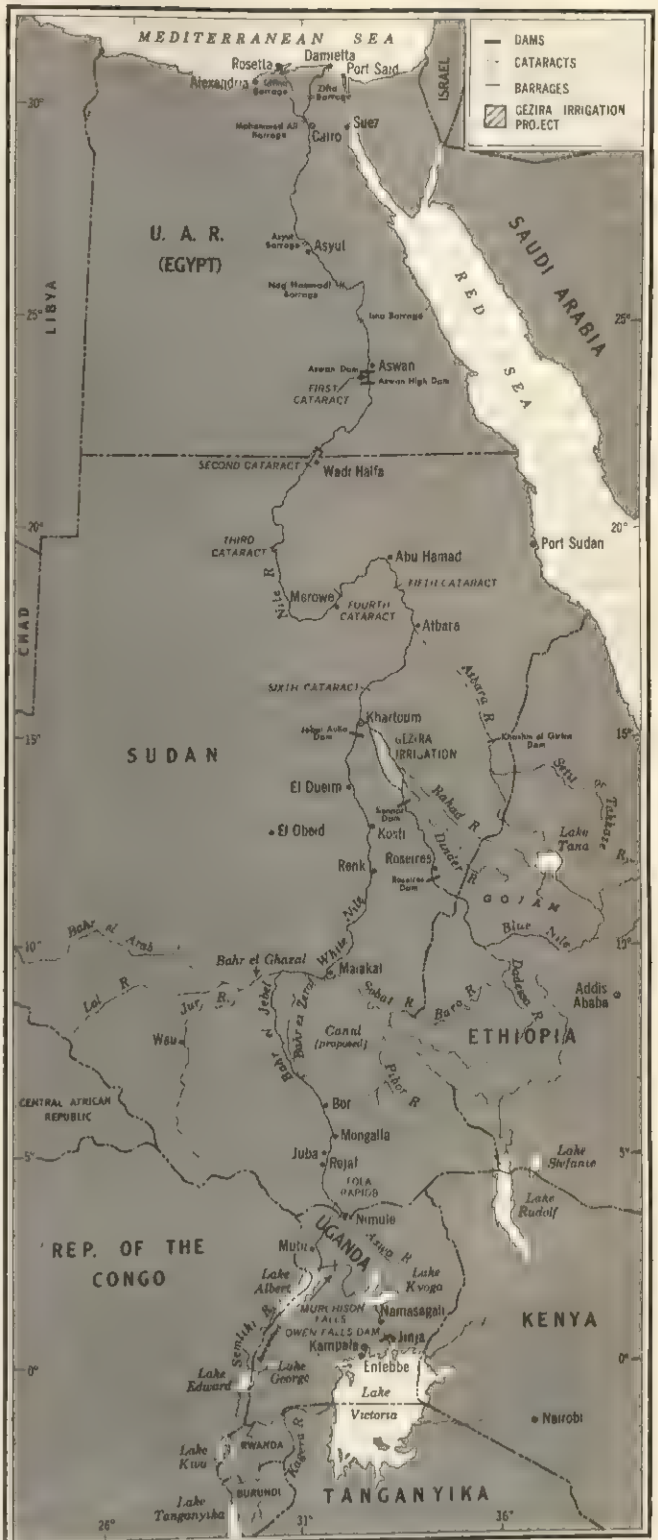
DHOW ON THE NILE AT ASWAN, UPPER EGYPT

White Nile.—The main stream of the White Nile begins on the Lake plateau of east Africa, where there are two separate river systems, the Victoria Nile and the Lake Albert system. Most of this country lies 4,000 ft. or more above sea level and thus enjoys a pleasant climate. Two rivers, the Niavarongo (Nyawarongo) and Ruvuvu, may justly be considered the headwaters of the White Nile, since they join together to form the Kagera (*q.v.*), the most important tributary of Lake Victoria. The Kagera is a stream 510 mi. long from the source of the Luvironza to its mouth, near which it is 80 yd. wide. Of the other tributaries of Lake Victoria (*q.v.*), the largest from the point of view of discharge is the Nzoia in the northeast, which has rather less than half the discharge of the Kagera and is torrential, with only a small flow in the dry season; it draws its water from Mt. Elgon and the high country to the northeast of Lake Victoria. The lake has an area of about 26,800 sq.mi. inclusive of islands and is like a small sea as it is subject to considerable storms. The Nile leaves Lake Victoria by the Ripon falls, which are now submerged because of the dam at the Owen falls a mile or more lower down.

At this point the supposed connection between the level of Lake Victoria and sunspots may be mentioned. From 1896 to 1927 maximum and minimum lake levels coincided with maximum and minimum sunspot numbers, thus giving rise to the theory of a connection. Later, however, this regularity disappeared. Moreover, on theoretical grounds the connection is unlikely, so the coincidence in the first of the records must be considered as accidental. Indeed, by the middle of the 20th century no connection between sunspot activity and any portion of the Nile had yet been established. The river below the lake, known as the Victoria Nile, is first beset with rocks and rapids but becomes navigable just above Namasagali (50 mi. from the lake). Below this are the combined Lakes Kyoga and Kwania, which are shallow with many

arms filled with papyrus-reed swamp. Masses of papyrus are broken loose by strong winds and sometimes have closed the Victoria Nile completely. Navigation has been abandoned and is being replaced by extensions of railways. Below Kyoga the Nile is navigable until it turns westward, after which there is a series of rapids finishing with the Murchison falls. There the Nile passes through a narrow cleft in the rock and falls a distance of about 120 ft. A short distance from the Murchison falls the Victoria Nile enters Lake Albert (*q.v.*). Lake Albert is at the tail end of another river system which starts from near some of the Kagera sources but on the northern side of the Mfumbiro, or Virunga, volcanoes. The principal headstream of this system is the Rutshuru river, which runs along the Rift valley northward to Lake Edward (*q.v.*). Lake George, which is much smaller, is joined to Lake Edward by a broad channel. The Semliki river, a fair-sized river, connects Lake Edward with Lake Albert. It flows in places through thick forest along the western side of the Ruwenzori range, of which it receives the drainage. Lake Albert lies between the high escarpments of the Rift valley, which in places come down abruptly to the water. It has an area of about 2,050 sq.mi. Below Lake Albert the river is known as the Albert Nile or Bahr el Jebel ("river of the mountain"), by which name it is known in the Sudan. For about 140 mi. the Bahr el Jebel is a placid stream, often with swampy edges abounding in mosquitoes; but at Nimule, on the Sudan-Uganda boundary, it ceases to be navigable for nearly 100 mi. as it descends from the plateau to the Sudan plains. Just below Nimule are the Fola (Fula) rapids, a fine sight, where the river rushes through a confined channel between rocks. After its arrival in the plains of the Sudan the country is flat except for rare rocky hills outcropping from the plain. Between Lake Albert and the plains the river receives some tributaries of a torrential nature, of which the principal is the Aswa from the southeast. The principal feature of the Bahr el Jebel when it reaches the plain is the large swamps of the Sudd region, where half its water is lost. Through these swamps the river winds between walls of high vegetation, papyrus, reeds and elephant grass, which except for lagoons and side channels extend from the river to the dry ground on either side, which may be miles away. Very few people are seen when once the river enters the swamps since only occasionally does it touch the higher ground. The country on the edge of the swamps provides good grazing, which lasts into the dry season, as the river, when high, floods a lot of country that is not permanent swamp. Most of the tribes of these southern plains, Nuers, Dinkas and Shilluks, are cattle-owning people living in a very primitive fashion. In the 19th century the Bahr el Jebel was frequently closed by blocks of vegetation (Arabic, *sudd*). Between 1899 and 1904 the river, which had been completely blocked over long distances, was cleared. Since navigation became regular and frequent these blocks have only very rarely been formed in the main stream, though less-frequented streams are occasionally blocked. About halfway through the swamps a separate channel, known as the Bahr ez Zeraf (Bahr az Zaraf) ("river of giraffes"), has been formed near the edge of the dry ground on the east and follows an independent course to the White Nile. In former times it was sometimes connected with the Bahr el Jebel, and a permanent connection has been made by means of two cuts dredged where the two streams are close together. At the tail end of the swamps the Bahr el Jebel is joined by the Bahr el Ghazal from the west and the two together flow eastward as the White Nile, being joined later by the Bahr ez Zeraf. The Bahr el Ghazal ("river of gazelles") is formed by the junction of a number of torrents coming from the southwest and west. The main stream is the Jur, which is navigable in flood up to a point south of Wau, the capital of the Bahr el Ghazal province. Next to the Jur in size is the Lol, into which a number of tributaries flow. It ends in swamps to the west of the Jur, as also does the Bahr el 'Arab; other streams end in swamp to the east. The effect of the swamps is that very little water flows out of the mouth of the Bahr el Ghazal into the White Nile. In the southern part of the Bahr el Ghazal basin the principal tribe is that of the Azande, who came originally from the Congo and are agriculturalists and craftsmen.



ADAPTED FROM A MAP COMPILED BY THE SURVEY OF EGYPT

THE NILE RIVER AND ITS TRIBUTARIES

The Sudd region of large permanent swamps ends at the junction of the Bahr el Ghazal and the Bahr el Jebel, although there is some swamp fringing the White Nile nearly as far as the mouth of the Sobat. The Sobat draws the greater part of its water from the Ethiopian plateau, though a little comes from the south. It is formed of two main streams, the Baro flowing from east to west and the Pibor from the south. From the Ethiopian mountains to the White Nile the country is flat grass plain liable to be flooded in the rains and in parts waterless in the dry season. The Sobat is in flood from July to October on its headwaters and, as a result

of the inflow from flooded areas, remains high at its mouth until December. It is navigable in flood to Gambela on the Baro and to Pibor Post on the Pibor, but the journey for the greater part is monotonous. The Pibor is occasionally blocked by vegetation. From the Sobat mouth to Khartoum the White Nile is a wide placid stream with a very small slope and often a narrow fringe of swamp. After Jebelein (Al Jabalayn) the country gradually becomes more arid and savanna forest gives place to thorn scrub, until near Khartoum it is almost desert. At Kosti the railway from Khartoum that follows the Blue Nile southeastward to Sennar and then turns southwestward on its way to El Obeid crosses the White Nile on a bridge with an opening span. Twenty-five miles from Khartoum is the Jebel Aulia dam, containing a lock, which forms a reservoir the effect of which, when full, extends beyond Renk, 280 mi. upstream.

Between Malakal and Khartoum end the regions of Negro people speaking their own languages—Bantu in the far south and then Sudanic—and begins a region where the people are of mixed Arab and Negro descent and speak Arabic. In fact, Arabic is understood by riverside people and people on the main routes all over the southern Sudan, while in Uganda and east central Africa the lingua franca is Swahili.

Blue Nile.—This is the source of nearly 70% of the Nile flood. The reputed source of the Blue Nile is a spring to the south of Lake Tana (*q.v.*) in Ethiopia, from which flows the Little Abbai or Abbai, the principal tributary of the lake. The lake is in a basin at an altitude of about 6,000 ft. (1,840 m.), but with high mountains at no great distance. It has an area of about 1,418 sq.mi. (3,673 sq.km.) and is shallow. The Blue Nile leaves the lake over a series of rapids and very soon drops into a deep gorge in places 4,000 ft. below the general level of the plateau. Tracks descend to the river at places where at low stage there are fords. It is usually a two days' journey with mules to descend, cross the river and climb up the other side of the canyon. Tributary streams have cut similar ravines, and the scenery is magnificent both in scale and ruggedness. It is not possible to travel along the bottom of the gorge and the river is continually interrupted by rocks and rapids. There is a bridge at Shafartak where the road from Addis Ababa to Gojam crosses the river. Only a small portion of the Blue Nile water comes out of Lake Tana; by far the greater part is from tributaries, some of which are important streams, for example the Bashilo, Jamma, Guder, Dadessa (Didessa), Dabus, Balas, Dinder and Rahad. The water is derived from the rain that falls on the Ethiopian plateau and not from melting snow as sometimes stated. The highest mountains in Ethiopia reach 15,000 ft. but snow seldom falls on them.

A dam was under construction in the 1960s at Roseires and halfway between there and Khartoum is the Sennar dam, by means of which an area of 1,000,000 ac. in the Gezira between the Blue and the White Niles is irrigated. The water is impounded in flood and used in February and March. It is a good example of co-operation —originally between the government, a foreign company holding a concession and the Sudanese tenants, then, after the concession had terminated, between the government and the tenants only. The Gezira project is well planned, and irrigation is based on careful measurement by weirs and other devices of the quantities of water entering the feeders from the main canal. The principal crops are cotton, millet and *lubia* (a kind of bean). Between Sennar and Khartoum the Blue Nile receives two tributaries: the Dinder and the Rahad. These, like the Blue Nile, are torrential but, unlike it, dry up entirely except for pools (though both are considerable streams in flood).

Main Nile.—The main stream, from Khartoum northward, flows between deserts with a narrow strip of vegetation on either side. Where the soil permits, the banks and neighbouring flatland are cultivated by the use of Nile water and support a small population. These conditions continue to Aswan and a little farther north. In this stretch the Nile receives its last tributary, the Atbara river (*q.v.*), which in flood is a large muddy river and in the dry season is a string of pools. A dam was under construction at Khashm el Girba (Khashm al Jarbah). The Atbara's principal tributaries are the Setit, or Takkaze, and the Bahr as Salam (Angareb). From Abu Hamad onward the valley is often rocky and desolate, particularly in the neighbourhood of the Fourth cataract and for more than 100 mi. S. of Wadi Halfa, where the country is known as the Batn al Hagar ("belly of stones"). Wadi Halfa is just below the Second cataract and is within the area affected by the heightened Aswan reservoir, which ponds water up as far back as the cataract. The low Aswan dam, which has been raised twice, has a height of nearly 53 m. (174 ft.) and a length of 2 km. (1½ mi.) and stores 5,300,000,000 cu.m. of water. (The high Aswan dam is discussed under *Irrigation, Flood Control and Water Utilization*, below.)

From Aswan northward to Cairo the river is bordered by a flood plain of alluvium gradually increasing to a maximum width of about 12 mi. which is cultivated by irrigation. Outside this is the desert. At the beginning of the 20th century basin irrigation was practised down to the head of the delta. In this system the land is watered by short canals, which can receive water only when the river is in flood. These deliver the muddy water on to the land, which is divided into compartments or basins by cross-banks running from the river bank to the higher desert edge. The water is held in these basins to a depth of several feet for some weeks and deposits its mud. During this time the land is well soaked, the river falls and the remaining water is then returned. After this seeds are planted in the mud to produce the single annual crop, which gets only such extra water as can be lifted from wells. This system was in use for thousands of years without any deterioration of the soil; but with an uncontrolled river the area that could be watered was variable and liable to be reduced in a low flood, with the possibility of famine. In perennial irrigation as distinguished from flood irrigation much smaller quantities of water are run on to the land every two or three weeks and two or three crops are grown in the year. This began to develop on a large scale from canals in the time of Mohammed Ali Pasha toward the middle of the 19th century. A necessary feature is the barrages or low dams which have been built across the Nile at various points to enable its level to be raised so that it can flow at all times into main canals, whose heads are just above the barrages. From the main canals there are branch canals, and these again divide into smaller canals called distributaries, which deliver the water to irrigation ditches and so to the land. By the end of the 19th century cultivation in the delta itself was all perennial, depending on the Mohammed Ali barrage (below Cairo at the head of the delta), above which the three main canals of lower Egypt begin; in 1903 an auxiliary barrage was built at Zifta (*q.v.*) 54 mi. downstream. During the 20th century barrages were built at Nag' Hammadi and Asyut in upper Egypt, by means of which a large part of upper Egypt was converted to the perennial system and another barrage at Isna improved basin irrigation. During the time of low supply, when all the water is needed for irrigation, the Rosetta (Rashid) branch is closed at the barrage and the Damietta (Dumyat) branch nearly so, while both are completely closed near the sea: the first by the Idfina barrage with its sluices, the second by an earth bank built each year by February and washed away by the rising flood in August (during this time waterborne traffic in the delta follows the canals). The crops grown during the low stage of the river are cotton, rice, sugar cane, peanuts, sesame and millet. In the flood season the principal crop is maize (corn) and in the winter the crops are wheat, barley, clover, beans, flax, onions and lentils. Cotton is the most valuable crop and occupies more than one-quarter of the total cultivated area. It is also Egypt's principal export. The Nile from Aswan to the sea is controlled in the interests of irrigation, though control is not complete in flood time. (*See* also *Hydrology*, below, and the *Physical Geography* and *Economy* sections of EGYPT.)

Climate and Health.—In Egypt the months May to October are hot in the daytime, but there is a considerable drop in temperature after sunset. The winter months usually have clear bright days with cool or even cold nights. The climate of the northern Sudan is similar except that the temperatures are higher. Upper Egypt and the northern Sudan are characterized by low humidities, and the region from Halfa to Atbara is one of the driest in the world. In the central Sudan from Khartoum to Renk

or Roseires during the months of December, January and February the days are not unduly hot, and the nights are cool, while the humidity is low; then the temperature increases until May or June, after which the onset of the rains causes it to drop; September and October are liable to be oppressive. In the southern Sudan the average temperature is lower than farther north and varies less through the year; the highest temperatures occur from January to April and the lowest are in July and August. The climate of the high country of Ethiopia and central Africa is temperate, and above 5,000 ft. the nights are cold. Around Lake Victoria the temperature does not vary much through the year.

The principal features of the rainfall are as follows: (1) There is a little rain on the Mediterranean coast (from 5 to 8 in. annually) and over the delta, but this decreases rapidly with distance from the sea, being about 1 in. in Cairo; it falls usually in the months from November to March. (2) A region extending from just south of Cairo to just north of Atbara is practically rainless. (3) There is next a steady increase of rainfall southward of the rainless region. (4) Regions of fairly heavy rainfall are found on the Ethiopian and Lake plateaus, where a total of more than 72 in. is reached in places, the average rainfall of both plateaus being about 50 in. On the whole the rainfall of the Nile basin is scanty, and hence for the size of its basin the discharge of the Nile is small. From Khartoum southward over the Sudan plain and in Ethiopia the maximum of rainfall is in July and August, but the rainy season is increasingly long toward the south and as the altitude of the country increases. On the Lake plateau there is no month when rain may not fall. There are two minima and maxima, the minima being in January and June–July.

In the southern and central parts of the basin, malaria, carried by the anopheline mosquito, is common. All over the basin dysentery and typhoid fevers are endemic. The parasites that cause these are usually taken in food, while water and flies are also agents of infection. In Egypt and some other parts of the basin schistosomiasis (bilharziasis) and ancylostomiasis, diseases caused by microscopic worms, are widespread. They are either contracted by drinking infected water or by wading or bathing in it. In certain districts relapsing fever occurs, transmitted by the bite of a tick that lives in cracks in the ground or in houses and comes out at night. Sleeping sickness in the southern Nile basin was formerly responsible for many deaths. However, as a result of stringent control measures, it has practically disappeared. It is carried from one person to another by the bites of species of tsetse flies. Flies of the same genus carry trypanosomiasis of animals and so cause mortality among cattle, horses and donkeys.

Vegetation.—The desert region outside the Nile valley extends from the Mediterranean to about the latitude of Atbara. Much of this area is almost rainless, and there is no vegetation except in favoured places such as the oases, where underground water comes to the surface, or along drainage lines where after rain the subsoil may remain moist for a long period. As regions of scanty but regular rainfall are reached, the country becomes dotted with small thorny shrubs, mostly acacias. These begin about the latitude of Atbara and grow increasingly thickly toward the south. After rain the country becomes green with grasses and small herbs but these rapidly dry up after the rain ceases.

South of this are types of savanna country. The first is thorny savanna containing small thorny trees and after the rains grass and herbs. This covers much of the central Sudan from latitude 10° to 15° N.

South of this is found true savanna country, consisting of open grass plains on which trees are rare except in a few places near the rivers, and on which the grass may grow from 6 to 10 ft. high. During the rains these plains are often swampy. True savanna covers a good deal of country from Malakal to Bor and from the Bahr el Jebel to the foothills of the Ethiopian plateau. During the dry season, which lasts about half the year, the grass dries, and over parts of the Lake plateau and most of the southern Sudan it is burned every year. This kills many species of trees and stunts the growth of the remainder, so limiting the vegetation. In the savanna zone the rivers are often fringed with reed swamp, more particularly the Bahr el Jebel in the Sudd region from Lake No to Bor and also the lower Bahr el Ghazal. In this swamp grow papyrus, tall reeds, and floating plants such as *Vossia cuspidata*, *Echinochloa* and *Pistia stratiotes*. Papyrus swamps are also found in the valleys of the Lake plateau. In 1958 the water hyacinth (*Eichhornia*), a dangerous pest, appeared on the White Nile and is now found from Juba to Jebel Aulia, and on the Sobat and Bahr el Ghazal. It is also found in the drains of lower Egypt.

The true savanna country changes into savanna forest, which fringes the Blue Nile near Roseires and southward and covers the western slopes and parts of the plateau of Ethiopia, the southern parts of the Bahr el Ghazal basin and large areas of Uganda, the Lake plateau and its slopes. Savanna forest consists of trees of medium height casting little shade, while the ground is covered with grass and perennial herbs. Tropical rain forest does not exist in great quantity in the Nile basin, but it is found in river valleys along the Nile-Congo divide and in patches on the Lake plateau and in Ethiopia. Rain forest is characterized by a large number of species and several strata of vegetation, so that practically all the space is utilized and a wonderful luxuriance of plant life results.

(H. E. Ht.)

River Fauna.—At least 55 genera and 112 species of fishes are known from the Nile system, but only 16 species are endemic to the area. The greater number of species is recorded from the White and lower Niles, only about one-third of these also occurring in the Blue Nile and then mostly below Roseires. The Blue Nile has, however, a slightly greater proportion of endemic species, all of the genus *Barbus*, and confined to its upper reaches. The Aswa river, a tributary of the upper Nile, has a peculiar ichthyofauna composed of typical Nilotic species and others characteristic of the Lake Victoria basin. Nonendemic Nilotic species are widely distributed in east and west Africa, particularly the Niger system. Notable species are the perchlike *Tilapia nilotica*, the giant Nile perch (*Lates niloticus*), which may weigh more than 200 lb., and several species of catfishes including the Raad or electric catfish capable of producing a discharge of 300–400 volts, *Synodontis batensoda* which habitually swims upside down, and the air-breathing catfish *Clarias lazera*. The common eel penetrates as far as Khartoum. Fishes feature in the graphic art of ancient Egypt and certain species were apparently venerated; *e.g.*, the snoutfish (*Mormyrus caschive*) and the Nile perch.

The reptiles most intimately associated with the Nile are the Nile crocodile, found in most parts of the river, the soft-shelled turtle, and three species of monitor lizard: *Varanus griseus*, an essentially Asian and north African species, ranges along the Nile to about the Atbara where it meets the northerly limit of distribution of the savanna species (*V. exanthematicus*); the Nile monitor (*V. niloticus*), occurs throughout the river system, except in lower Egypt. About 30 species of snakes, of which less than half are harmless, are associated with the Nile river; the range of some has been extended by ship transportation.

The hippopotamus was common throughout the Nile system in historical times but is now extinct except south of Khartoum.

(P. H. Gr.; A. G. C. G.)

History of Exploration.—The earliest traces of man are stone implements found in many parts of the basin, some of which were made perhaps 100,000 years ago. The most recent in Egypt are found with early pottery and come down to *c.* 4500 B.C. The historical period begins *c.* 3400 B.C. and follows a period known as predynastic in which metal instruments began to be used as well as those of stone. When the early flint-implement people lived, the climate of north Africa was warm and humid. Lakes and rivers existed in what is now desert and the country was covered with vegetation and inhabited by animals now only found in tropical Africa. The mildness of the climate allowed men to live in shelters made of reeds or branches and did not force them to live in caves, as in northern countries, where traces of their occupation would have been preserved. Consequently the only remains of these early men are their durable flint instruments, which are widespread over northeastern Africa. Gradually the climate became drier, the rivers shrank and ultimately, perhaps 20,000 years ago, desert conditions were established as they are at present. The result of this change was to concentrate people on the edges of the

Nile valley. In the valley itself the river probably covered most of the land when in flood and left huge marshes when it fell again and retired to its trough. In these marshes primitive people living on the edges of the valley hunted hippopotamuses, water-loving antelopes and wild fowl. As the rainfall over north Africa decreased and the country became arid, the Nile shrank to something like its present volume, and the beginnings of agriculture probably started on the edges of the valley.

Actual history in the basin begins in Egypt 5,000 or 6,000 years ago and is based on deductions from pottery and utensils found in tombs. Later there are the inscriptions, pictures and carvings on the monuments which record contemporary events, and so down through ancient Egyptian, Greek, Roman and Arab times to the present. Little is known of the early history of the Nile basin outside Egypt and this comes from the excavations in the northern Sudan and occasional references on Egyptian monuments to people farther south. It seems likely that the ancient Egyptians, although they traded down the Red sea as far as Somalia and up the Nile beyond Khartoum, knew nothing of the source of the river which they deified as Apis (Hapi), who irrigated and nourished their crops. Herodotus, who visited Egypt *c.* 460 B.C. and traveled up to Aswan, has left some account of the country and a little about what lay to the south as far perhaps as the beginning of the Sudd region. He observed that Egypt was a land given to the Egyptians by the Nile. By the 1st century A.D. trade down the Red sea to India and the east coast of Africa was well established, and this must have led to trade with the interior. It was probably due to this that rumours of snow-capped mountains and great lakes in the interior reached the Mediterranean. Because of the difficulties of travel in the Sudan it seems unlikely that the connection of the Nile with these was actually established; it was probably an intelligent guess. Strabo about the beginning of the era says that it was well known that the annual rise of the Nile was due to rain on the high mountains of Ethiopia. Ptolemy, who lived in Alexandria in the 2nd century A.D. and wrote treatises on astronomy and geography, thought that the White Nile came from the high snow-covered mountains in central Africa, called the Mountains of the Moon (commonly identified with the Ruwenzori range), and passed through two lakes. His map corresponds in a general way with what actually exists and must have been a collation of information then current as travelers' tales.

With Portuguese expeditions to Ethiopia in the 15th and 16th centuries more definite knowledge was obtained. The first European to see the source of the Blue Nile was Father Pedro Páez, a Spanish Jesuit, who visited it in 1613. Later, about 1770, James Bruce, the British explorer, spent some time near Lake Tana and the headwaters of the Blue Nile and then returned from Gondar to the Blue Nile at Sennar and so down the Nile to Cairo.

Modern exploration of the Nile basin begins with the conquest of the northern and central Sudan by Mohammed Ali Pasha and his sons from 1821 onward. As a result of this the Blue Nile was known as far as its exit from the Ethiopian foothills, and the White Nile as far as the Sobat mouth. During his last visit to the Sudan about 1837 Mohammed Ali gave orders for the exploration of the White Nile so as to solve the problem of its origin, which had interested the civilized world for 2,000 years. Three expeditions under a Turkish officer, Selim Bimbashi, were made between 1839 and 1842 and two got to the point about 20 mi. beyond the present port of Juba, where the country rises and rapids make navigation very difficult. These expeditions were accompanied by Georges Thibaut (Shawki Ibrahim), Jacques Pons d'Arnaud (Arnaud Bey) and Ferdinand Werne who published accounts of their journeys. After these expeditions traders and missionaries penetrated the country and established stations in the southern Sudan. From an Austrian missionary, Ignaz Knoblecher, in 1850 came reports of lakes farther south. In the 1840s the missionaries Johann Ludwig Krapf, Johannes Rebmann and J. Erhardt, traveling in east Africa, saw the snow-topped mountains Kilimanjaro and Kenya and heard from traders of a great inland sea which might be a lake or lakes.

These reports led to fresh interest in the Nile source and to an expedition by Richard Francis Burton and John Hanning Speke (*qq.v.*), who followed a trade route of the Arabs from the east coast and reached Lake Tanganyika. On the return journey Speke went north and reached the southern end of Lake Victoria, which he thought might be the origin of the Nile. This was followed in 1860 by another expedition by Speke and J. A. Grant under the auspices of the Royal Geographical society. They followed the previous route to Tabora and then turned toward Karagwe, the country west of Lake Victoria. There they saw the high Mfumbiro, or Virunga, mountains 100 mi. to the west (they thought that they might be the Mountains of the Moon) and discovered the Kagera river. From the information that he was able to collect Speke thought that the Kagera must be the principal tributary of the lake. Continuing around the lake he finally reached the Ripon falls (1862), at which point he wrote "I saw that old Father Nile without any doubt rises in Victoria Nyanza." Speke then made his way northward with Grant, for part of the way along the Nile, until they reached Gondokoro, nearly opposite the present Juba. They heard rumours on the way of another large lake to the west but were unable to visit it and passed the information on to Sir Samuel White Baker (*q.v.*), who met them at Gondokoro, having come up from Cairo. Baker then continued his journey south and discovered Lake Albert. Neither Speke nor Baker had followed the Nile completely from the Ripon falls to Gondokoro, and Baker, who saw the northern half of Lake Albert, was told that it extended a very long way to the south. The discoveries of Speke and Baker are now commonly held to have settled the origin and course of the Nile, but at the time the unexplored gaps and the very elementary state of the science of hydrology led people to think that there was still an element of doubt. The question was settled when, between 1874 and 1877 Gen. C. G. Gordon and his officers followed the river and mapped part of it. In particular Lake Albert was mapped and Col. Charles Chaillé-Long, an American, discovered Lake Kyoga. In 1875 Henry (later Sir Henry) Morton Stanley (*q.v.*) traveled up from the east coast and circumnavigated Lake Victoria. His attempt to get to Lake Albert was not successful, though he traveled up the Katonga swamps and got as far as the escarpment above Lake George, from which he was forced to turn back by tribal unrest. Finally he marched to Lake Tanganyika and traveled down the Congo to the sea. In another memorable journey in 1889 to relieve Emin Pasha, Stanley traveled up the Congo and across to Lake Albert, where he met Emin and persuaded him to evacuate his Equatorial province, which had been invaded by the Khalifa's forces (*see* EMIN PASHA, MEHMED). They returned to the east coast by way of the Semliki valley and Lake Edward, and Stanley saw the snowy peaks of Ruwenzori for the first time.

Thus by 1890 the main features of the Nile basin were known, though there still remained much to be explored and also the business of map making, which 60 years later was still not fully complete in detail. After 1900 the expansion of perennial irrigation in Egypt and its beginnings in the Sudan created demands for more water when the river was low. These led to hydrological studies, and irrigation projects described below.

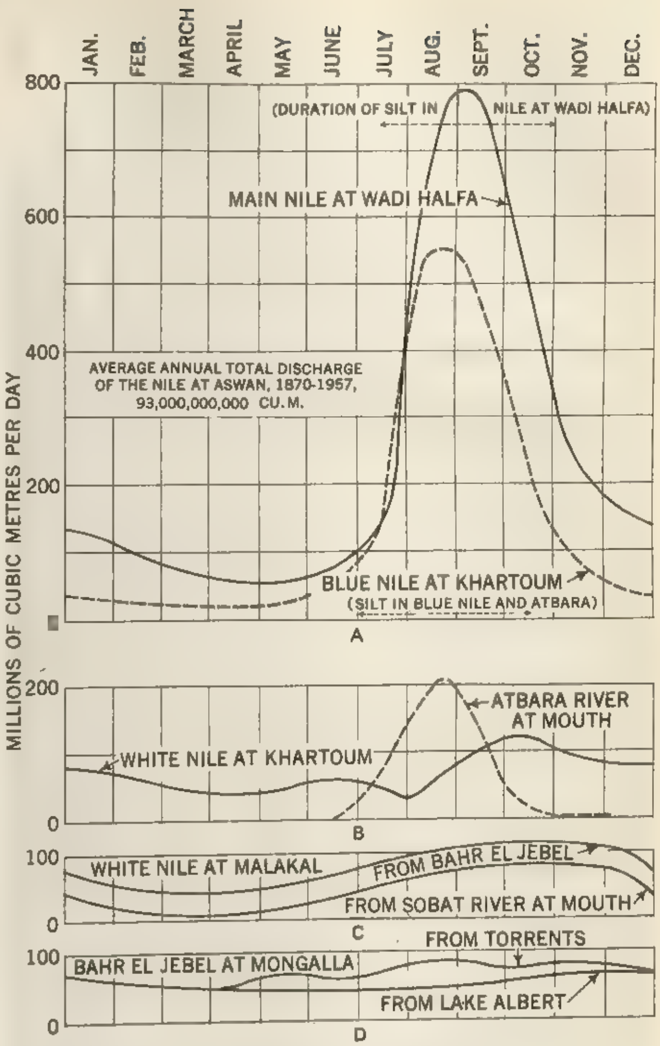
Hydrology.—Nile studies may be said to have begun at a very early date, as the ancient Egyptians recorded river levels on Nilometers, some of which still remain. However, before the 20th century there was very little detailed knowledge about the Nile water supply and its origin, and the greatest developments took place after World War I. The levels and discharges of the principal tributaries and of the main stream are now measured at many points from the Kagera, beyond Lake Victoria, to the sea, with the exception of the Blue Nile beyond the Sudan boundary. Between 1901 and 1904 Sir William Edmund Garstin made a hydrological reconnaissance of the White Nile from Lake Victoria to Khartoum, and C. E. Dupuis examined the Atbara and the Rahad and the Dinder (tributaries of the Blue Nile) and visited Lake Tana. The results of these reconnaissances, with recommendations for the improvement of Egypt's water supply were published in 1904 in a report on the basin of the upper Nile. In 1906 Sir Henry Lyons published his *Physiography of the Nile Basin*, in which was collected all the information from travelers and scientific explorers available at the time. In the previous

year the Sudan branch of the Egyptian Irrigation service had been formed, which with the Physical department was to continue studies of the upper Nile. In 1925 the Sudan formed an irrigation service, and in 1947 Uganda started a hydrological survey.

The principal feature of the Nile regime is the annual flood. The river at Wadi Halfa, where it enters Egypt, usually begins to rise in June, reaches its maximum at the beginning of September and then falls away at a decreasing rate. It is low from February to the middle of July, and during this time its natural supply is insufficient for the irrigation requirements of Egypt. Although the flood is a fairly regular phenomenon it varies both in volume and in date. These variations are important, since a very high flood brings danger of flooding in Egypt and the northern Sudan, and a low one may mean a shortage of irrigation water later.

The flood is caused by the Blue Nile and Atbara rivers whose waters come from rainfall on the Ethiopian highlands and bring down mud washed off the land surface into the many small streams that they form. The two rivers come down in flushes, which are gradually smoothed as they travel down the river. The average flows of the Nile and its principal tributaries are shown in the accompanying graphs. It is clear that the greatest part of the total flow is contributed by the Blue Nile and the least by the Atbara, but at the low time of the year the White Nile is the most important stream. The White Nile also receives some water from the Ethiopian highlands, which altogether produce 84% of the Nile supply, while the remaining 16% comes from the Lake plateau of central Africa. When the Blue Nile is rising rapidly it holds up the White Nile discharge, which begins to increase only when the rise slows down. The effect of the Blue Nile is therefore to make a natural reservoir of the White Nile, and this effect is now produced artificially on a greater scale by the Jebel Aulia dam, situated south of Khartoum a short distance up the White Nile, which adds 2,000,000,000 cu.m. to Egypt's low-stage supply. The Atbara draws its supply from the northern part of the Ethiopian plateau, but little is known of the hydrology of its tributaries. The rainfall that causes its flood comes from the same source as that falling in the Blue Nile basin, and this is probably the South Atlantic (*see* below). In flood its level fluctuates rapidly like that of the Blue Nile, and after the flood it soon ceases to flow. The Blue Nile receives two tributaries in the Sudan, both coming from Ethiopia, the Rahad and the Dinder. They are strong streams in flood but, like the Atbara, are reduced to pools later. When at their maximum, they produce together about 10% of the Blue Nile's discharge. Of the tributaries of the Blue Nile outside the Sudan practically nothing is known from a hydrological point of view. Lake Tana has been studied and only produces about 7% of the discharge of the Blue Nile. The lake is important because it offers the possibility of an economical reservoir for the joint use of the Sudan and Egypt and power for Ethiopia, where excess evaporation losses would be small.

About half of the discharge of the White Nile is provided by the Sobat, about half by the Bahr el Jebel and an insignificant portion by the Bahr el Ghazal. The Sobat is formed by two main streams, the Baro coming from Ethiopia and the Pibor coming from the south, though its main tributaries also come from Ethiopia. Flushes occur on the headstreams of the Sobat, but when they reach the plains they overflow and flood large areas of country. The effect of this is to smooth out all the peaks and to delay the arrival of the maximum at the mouth by a couple of months. The Sobat, like the Blue Nile and Atbara in flood time, brings down mud from Ethiopia, though only a small amount gets into the main White Nile. The graph C shows the average contributions to the White Nile of the Sobat and Bahr el Jebel. It will be noticed that the Bahr el Jebel's discharge varies very little throughout the year. This is due to the regulating effect of the large swamps of the Sudd region on the Bahr el Jebel. When a rise occurs upstream of the swamps, most of it flows out of the river into the marshes and only a very small part of the increase is left at their tail. As large areas are below the river level, the water that enters them is lost by evaporation and by transpiration from the luxuriant vegetation, with the result that the Bahr el Jebel loses



BASED ON MATERIAL OF THE MINISTRY OF PUBLIC WORKS, EGYPT

AVERAGE DISCHARGES OF THE NILE

nearly half its water in the swamps. In the case of the Bahr el Ghazal, which drains a large area having a fair rainfall, the tributary streams in their upper courses carry considerable volumes of water in flood (from July to October) although they are practically dry from January to April. Of this quantity that drains into the tributaries, estimated to be rather more than the discharge of the Sobat, only a trickle reaches the mouth of the Bahr el Ghazal. The Bahr el Jebel derives its water mainly from the equatorial lakes, but there is in addition a contribution averaging about 17% of the total from torrential tributaries joining between Lake Albert and Mongalla, which rise and fall quickly. During the dry season their contribution is negligible. The Bahr el Jebel immediately below Lake Albert does not fluctuate rapidly, since it is entirely controlled by the lake, which because of its size can only change its level slowly. Lake Albert receives supplies from two main sources, the Victoria Nile and the Semliki. The latter comes from Lake Edward and receives on its way the drainage from the western side of Ruwenzori and some small streams from the Republic of the Congo. The Victoria Nile comes from Lake Victoria through Lake Kyoga and provides about 80% of the inflow into Lake Albert. There is a small amount of drainage from swampy valleys into the Victoria Nile and Lake Kyoga, which in seasons of heavy rain may be considerable; but on the average the system is a source of loss.

Lake Victoria has an annual average outflow of 21,000,000,000 cu.m. A water balance sheet for the lake shows that rainfall and evaporation are approximately equal and about five times the outflow by the Victoria Nile or inflow from tributaries. The approximate equality of rainfall and evaporation makes the large lakes

of central Africa valuable as potential storage reservoirs. Lake Victoria was made into a reservoir (1954) by the Owen Falls dam on the Victoria Nile, just below its outfall from the lake. In this the surplus discharges of high years can be stored to meet the deficit of low ones. The fall from the lake is harnessed by a hydroelectric plant to provide power for industries in Uganda.

Origin of the Nile Flood.—It is known that the greater part of the Nile water comes from rainfall in Ethiopia. The development of meteorology in the 20th century made it clear that the causes of such phenomena as the Indian monsoon and other tropical rains must be sought in the general circulation of the atmosphere. In 1910 J. I. Craig put forward the theory that the Ethiopian rainfall is caused by a current of moist air coming from the South Atlantic across Africa. The following is the evidence. The possible sources of rain in Ethiopia are the Mediterranean sea, the Red sea, the Indian ocean and the South Atlantic ocean. The Mediterranean and Red seas are ruled out because of intervening deserts and the fact that there is no stream large enough to reach the sea on the eastern side of the highlands. On the whole the winds of the rainy season blow across Africa from the Gulf of Guinea to Ethiopia. The rainfall is heaviest over the coast and the Congo basin, diminishes over the Sudan plains and is again fairly heavy on the Ethiopian plateau. South and east of the plateau, rainfall is scanty and large areas are desert or semidesert.

Periodicity and Prediction.—Much work has been devoted to the search for periodicities in natural phenomena and the long series of records of the Roda (Cairo) Nilometer have afforded valuable material. The most complete portion extends, with gaps, from A.D. 622 to A.D. 1522 and gives maximum and minimum levels. In spite of uncertainties because of repairs and renewals of the gauge, to changes of the river channel, to vagaries of gauge observers and to defects in the records, much useful information can be extracted from them. When the maximum levels are plotted in order, the principal feature is the occurrence of terms of years when, on the whole, floods are above the average and of others when they are below; but there is no obvious regularity about their occurrence. Low floods may occur among high ones and vice versa. For example, in the latter half of the 19th century a very low and a very high flood occurred in successive years, with a difference at Aswan of 9 ft. between their peaks. Many people have analyzed the records, and periodicities have been found varying from 2 to 240 years in length, but all of them have small amplitudes of the order of 10 cm. The largest so far found has an amplitude of 17 cm., or 34 cm. between minimum and maximum floods. These periodicities are completely masked by the irregularities and, although they may have theoretical importance, are of no use for the practical business of attempting to forecast the flood.

Forecasts of the river, when they can be made, are of considerable value in the practice of irrigation. The flood of the Nile occurs when the tropical rain belt has moved north of the equator. Following the theory put forward by J. I. Craig (*see* above), many attempts have been made to find numerical relations between the Nile flood and other meteorological phenomena chosen from all over the globe, as a means of forecasting. Although some relations have been found nothing of practical value has emerged.

Two other types of forecast are successful and in regular use. The first depends on the time taken by rises or falls of the river to travel downstream and on the flattening that they undergo as they proceed. Past records of river levels have been analyzed, and from this analysis curves and tables have been made showing how long a well-marked change of level takes to travel over the various reaches of the river and how much is lost on the way. This varies with the height of the river. For example, the time from Roseires on the Blue Nile to Aswan, a distance of 1,540 mi., varies from 10 days at the top of the flood to 35 days at the lowest levels. This type of forecast is very useful when the Blue Nile and Atbara begin to rise, and plans must be made for the sowing of crops. The amount of these depends on the amount of available water, of which some must be retained in the Aswan reservoir so that it is not empty before the natural supply of the rising river is sufficient for the crops. If the flood is a high one, this type of forecast is again useful to predict the height to which the river is likely to rise in lower Egypt, so that suitable measures can be taken to prevent breaches of the river banks. The other successful type of forecast is based on the fact that when the rains in Ethiopia are over, usually by the end of October, the Blue Nile falls regularly in much the same manner each year. Consequently the discharge in one month influences those in the following months, and a forecast can be made in November for the following months up to May or even June. This forecast is extremely useful as it gives an idea of the water that will be available for summer crops and whether the prospects are favourable for a large area under rice.

Irrigation, Flood Control and Water Utilization.—In Egypt in the early 1960s about 6,000,000 ac. were cultivated by irrigation, of which 700,000 ac. were on the basin system of flood irrigation (derived from the pharaonic system of agriculture) and the remainder were on perennial irrigation utilizing dams and reservoirs and of great economic importance (see *Main Nile*, above; *see also* EGYPT: *The Economy*). In the Sudan about 1,000,000 ac. were irrigated in the Gezira (*q.v.*) by water taken into a canal just above the Sennar dam; about 1,200,000 ac. were irrigated by pumps drawing from the river; and an area in Northern province of about 90,000 ac. in good years was watered by flooding. Elsewhere in the basin of the Nile cultivation by irrigation is practically nonexistent.

The irrigation year may be divided into two parts, which are roughly from August to January when the river supply is in excess of requirements, and from February to July when it is necessary to add to the natural flow of the river by water stored from the previous time of excess. The storage of water in the Jebel Aulia reservoir begins in August when there is definitely an excess in Egypt. This is White Nile water, which is free from silt, and it is used for irrigation in Egypt as soon as the natural river is insufficient. The Sennar dam is in use from the middle of July to the end of March. Its reservoir is first of all filled to the level required to supply the Gezira canal and later to full storage level. During February and March the canal takes only water previously stored in the reservoir, since at this time Egypt has a right to all the natural flow. Further water is stored for Egypt in the Aswan reservoir from October, and this is drawn upon after the supply from the Jebel Aulia reservoir is exhausted. At the height of the flood the silt content of Nile water averages about 2,500 parts per 1,000,000 by weight, and for the whole flood period from July to October about 1,600 parts per 1,000,000. This is much less than is carried by many other rivers, for example the Colorado, the Missouri and the Indus. Most of this has passed by the time that the Aswan reservoir begins to be filled. It occasionally happens, however, that the reservoir is partially filled at the top of a high flood to reduce the maximum levels in Egypt. So far only an insignificant amount of mud has been deposited in the reservoir by this procedure. Nile water contains on the average about 170 parts per 1,000,000 of dissolved salts. This is not a great amount and is only about half that in the Thames, but more than in many other British rivers.

By the middle of the 20th century the rapidly increasing populations in Egypt and the Sudan had made further conservation works on the Nile urgent. Proposals for these were made in 1946 in *The Nile Basin*, vol. vii, by H. E. Hurst, R. P. Black and Y. M. Simaika, and were accepted as the policy of the Egyptian government in 1949. They involved as a main principle over-year storage, the theory of which was worked out by Hurst (*Transactions of the American Society of Civil Engineers*, Paper 2447 [1951] and *Proceedings, Institution of Civil Engineers*, part 1, vol. v [1956]). Over-year storage was essential, since in 1913–14, for instance, the whole discharge of the river had been less than were the requirements of Egypt and the Sudan in the middle of the 20th century. The projects comprised, in the first place, a large reservoir in Lake Victoria, produced by the Owen Falls dam, which would form the main reservoir for over-year storage and would also provide hydroelectric power for use in Uganda; by means of this, reservoir water would be stored in good years to supplement the supply of bad ones. An adjunct to this reservoir was to be a

regulator or low dam near the outlet of Lake Kyoga. Third, a reservoir in Lake Albert was required to control water from the Semliki river and the large quantity coming in seasons of unusually heavy rainfall from the tributaries of Lake Kyoga and the amount of water sent down to the Sudan and Egypt. Fourth, in view of the losses of water in the swamps of the Bahr el Jebel, as it was obviously useless to provide large storage reservoirs if half their outflow would be lost, the Jonglei diversion canal was designed to bypass the swamps; this would leave the Bahr el Jebel at Jonglei below Bor and join the White Nile between the mouths of the Bahr ez Zeraf and the Sobat. A regulator would divert about half the discharge down this canal, and the remainder would flow down the Bahr el Jebel at a level that would reduce the losses to normal, so that there would be a gain of water in addition to the regulated distribution produced by the lake reservoirs. The Jebel Aulia reservoir was to continue to act as it already did and to store water mainly from the Sobat flood. Fifth, a projected dam at the outlet of Lake Tana, if the lake could be used to its full capacity, would provide water for the increase of cultivation in the Sudan, a measure of over-year storage and also a reserve in case of emergency in Egypt, such as might be caused by a very low flood, as well as hydroelectric power for Ethiopia.

Finally, a large dam on the main Nile below the Atbara would provide a reservoir for flood protection with, in addition, some stored water from all floods except the low ones, for use in the following low stage. Nothing was planned to reduce the losses in the Bahr el Ghazal basin, the only large source still remaining.

These projects could only be carried out after agreements between Egypt, the Sudan, Ethiopia, the Republic of the Congo and the east African territories. The Owen Falls dam has been built and the Sudan carried out a far-reaching investigation into the effects of the Equatorial Nile projects on the country and its people. (See *Report on the Equatorial Nile Project and Its Effect on the Southern Sudan*, 1954.)

The Equatorial Nile project would develop storage of White Nile water nearly to its maximum, but could do little to store the floodwaters of the Blue Nile and Atbara, which at present flow to sea. From the point of view of capacity the best situation for a reservoir to do this would be on the main Nile below the Atbara junction, where it would deal with the combined flow. To meet this need a proposal was made for a high dam (Sudd al Aali) at Aswan, and surveys showed that the valley had no outlets and was of a favourable shape with a large capacity. A project was drawn up by Egypt for a rock-fill dam with tunnels round its ends in the granite river bank to carry the flow, at a site about 4 mi. upstream of the present dam. The maximum water level would be about 60 m. above the top level of the present reservoir, and the reservoir when full would extend about 90 mi. beyond Wadi Halfa (which would be inundated), and would have a capacity of 157,000,000,000 cu.m., of which the lowest 30,000,000,000 would be used as a silt trap, the next 97,000,000,000 for over-year storage and the top 30,000,000,000 for flood protection for Egypt. Evaporation is heavy in this region, but the Aswan site is the most favourable so far found, and high evaporation is inseparable from storage of a large part of the flood. Work on the Aswan high dam was in fact begun in 1960 with Soviet financial and technical assistance after agreement between Egypt and the Sudan was reached regarding sharing of water and indemnities to the Sudan for flooded lands. In 1964 the Nile was diverted through the tunnels.

The project can be of use both to Egypt and the Sudan and forms an essential part of any comprehensive scheme for Nile conservation. It would also produce a large amount of hydroelectric power. The Sudan government also prepared a Nile Valley plan which provided, in addition, for dams at Roseires, Atbara and on the Baro in Ethiopia for annual storage, and dams at Semna (within the Aswan high dam reservoir) and in the Blue Nile canyon in Ethiopia for over-year storage. It has employed an electronic computer to try out the working of the plan based on the years 1905–52. A hydroelectric power scheme on the low Aswan dam began working in 1960. Any of the dams already mentioned offers a possible site for the development of power, but a drawback in some cases is the distance between the place where the power could be produced and that where it could be usefully employed. The primary need is for water for irrigation.

NILE, BATTLE OF THE, was fought between the British and French fleets in Abu Qir bay, near Alexandria, on Aug. 1, 1798.

The British government, having heard that a large-scale expedition was to sail from Mediterranean ports under the command of Napoleon Bonaparte, ordered the earl of St. Vincent, the commander in chief of the main British fleet, which was at that time based on Lisbon, to detach ships under Rear Admiral Sir Horatio Nelson to reconnoitre off Toulon and to watch enemy movements. But Nelson's own ship, the "Vanguard," was dismasted in a storm on May 20, 1798, and his frigates, dispersed, returned to Gibraltar. Meanwhile, St. Vincent had sent him a further detachment which joined Nelson on June 7, bringing his strength up to 14 ships of the line and one brig.

The French expedition eluded the British warships, sailed first for Malta, which was seized early in June, and established a garrison at Valletta. After a week at the island Bonaparte sailed with his armada for his main objective, Egypt. Finding Toulon empty, Nelson was left to guess the French purpose. He guessed right but, having no frigates for reconnaissance, missed his quarry, reached Egypt first, found the port of Alexandria empty, and impetuously returned to Sicily, where he revictualed. Then, baffled but determined, he made for Egypt once more and on Aug. 1 at last descried the main French fleet of 13 sail of the line and 4 frigates under Adm. F. P. Brueys at anchor in Abu Qir bay.

Although there were but a few hours before nightfall, and although Brueys, with his ships securely ranged in a sandy bay flanked on one side by a battery mounted on Abu Qir Island, was in a strong defensive position, Nelson gave orders to attack at once and to concentrate on the French van. He left full initiative to his subordinates with great success. Captain Thomas Foley in the "Goliath" led in and, when he saw how the French were disposed, decided to risk finding sufficient depth of water to get his ship round the head of the French line and thus inside and behind their position. He succeeded, and was followed by Samuel Hood in the "Zealous," by Davidge Gould in the "Audacious" and by Sir James Saumarez, Nelson's second-in-command, in the "Orion." Nelson himself, in the "Vanguard," was the first to attack the French from the seaward side and he was followed by each succeeding ship except the unlucky "Culloden" which struck on a shoal. Thomas Troubridge, her captain, was able to signal a safe course to the "Alexander" and the "Swiftsure," which were the last to come into action, after nightfall.

For some hours the battle was fierce, Nelson himself being wounded in the head. The climax came about 10 P.M. when Brueys' 120-gun flagship "L'Orient," by far the biggest ship in the bay, blew up with most of her ship's company, the admiral included. Shortly afterward the fight was resumed and it continued for the rest of the night.

Only two French ships of the line, "Le Généreux" and Rear Admiral Villeneuve's flagship "Le Guillaume Tell," escaped capture or destruction. Together with two frigates, they beat out of the bay during the morning of Aug. 2, no British ship being then in a condition to dispute their passage, though none, not

even the "Culloden," had actually sunk. Nelson's losses were 218 killed and 677 wounded. The French lost about ten times that number. "Victory," said Nelson, "is not a name strong enough for such a scene."

The effect of the battle of the Nile was manifold. It heartened Europe to resist French expansion and isolated Bonaparte's army in Egypt, ensuring its ultimate disintegration. It also ensured that Malta would in due time be retaken from the French, and restored British prestige throughout the Mediterranean. Nelson himself was rewarded with a peerage.

See Oliver Warner, *The Battle of the Nile* (1960). (O. M. W. W.)

NILGIRIS ("blue mountains"), a hill system in south India giving its name to an administrative district of Madras. The Nilgiris form a plateau at a general elevation of 6,500 ft. above sea level, rising abruptly from the plains except on the north where their base rests upon the Wynaad and Mysore uplands, at about 2,000–3,000 ft. The general aspect of the higher parts is grassy and downlike, interspersed with *shola* or woodland. The Wynaad (partly included in the administrative district) and the Ochterlony valley comprise broken valleys, once wholly forested, now dotted with tea and coffee plantations, whose output provides the chief commerce of the district. The timber forests include teak; eucalyptus and Australian wattle have been planted extensively on the higher Wynaad country. Animal life includes the Nilgiri ibex (*wariatu*), tiger, panther (including the black variety), wild boar, bear, muntjac (barking deer) and chital (spotted deer); quail, partridge, snipe, wood snipe and woodcock, spur fowl and the indigenous jungle fowl are among the game birds. The Nilgiris are detached from the main Deccan plateau by the deep Moyar river valley. Other streams are the Bhavani, the Pykara and the Calicut; none is navigable but with their tributaries they are fished for mahseer, Carnatic carp and trout. Archaeological monuments abound. The Nilgiris are inhabited by the tribal Kota and Toda (*qq.v.*).

The Nilgiris are increasing in importance for hydroelectric power. The Pykara project (70,200 kw. installed capacity) and the Moyar valley power station (36,000 kw.) are the main plants.

NILGIRIS DISTRICT is the smallest in Madras: area 984 sq.mi.; pop. (1961) 409,308. The administrative headquarters are at Ootacamund (*q.v.*), the chief summer resort of south India, at the terminus of a branch line, 41 mi. N.N.W. of Podanur junction on the main Southern railway (Madras to the west coast). The line is rack metre-gauge from Mettupalayam, 30 mi. below Ootacamund. The mean annual temperature is 14° C. (58° F.); there are night frosts in December–January above 6,000 ft., at only 11° from the equator. The mean annual rainfall is 49 in. Besides Ootacamund other main towns are Coonoor, Wellington, Dotacamund and Kotagiri. (L. D. S.)

NILO-HAMITES, a cluster of peoples of east Africa, defined by their languages which are mainly Nilotic with influence from Cushitic or Hamitic sources (*see* NILOTES). The Nilo-Hamitic-speaking peoples include several groups, each defined by closely related languages and customs. Most Nilo-Hamites are pastoralists, and it is certain that all these groups have been pastoralists at one time or another; all lack centralized political authority but in most cases recognize the partially secular authority of prophets or rainmakers; and almost all have a system of age sets based upon circumcision as the basis of political organization (*see* AGE SET).

The most northerly Nilo-Hamites are pastoral groups of the southeastern Sudan, of whom very little is known: they include the Didinga, Murle, Longarim and Nyangiya, with a combined population of about 35,000 in the 1960s. To their west are the Bari-speaking tribes west of the Nile, who practise agriculture and seem to have adopted much of the culture of their Sudanic-speaking neighbours. They comprise the Bari (*q.v.*; 35,000), Kakwa (with whom may be counted the Fajelu and Nyangbara, in all 125,000), the Kuku and Nyefu (30,000), the Mandari (36,000) and smaller groups. East of the Nile near the Uganda border are the Lotuko-Lokoiya group of tribes (about 70,000).

The central Nilo-Hamites are mostly pure pastoralists and include the Karamojong (56,000), Jie (18,000) and Dodoth (20,000) of northeastern Uganda, the Topotha, Donyiro and others of the southeastern corner of the Sudan (in all 45,000), the Turkana (about 80,000) of the northern Kenya desert. The Teso (463,000) and Kumam (56,000) of central Uganda and the outlying Teso group known as Tesio in Kenya (about 45,000) have forsaken pastoralism and today practise sedentary agriculture.

The southern Nilo-Hamites speak either Nandi or Masai. The former include the Nandi (*q.v.*; 117,000), Kipsigis (Lumbwa; about 160,000), Keyo (Elgeyo; 40,000), Tuken (Kamasya; about 67,000), Suk (Pokot; 45,000), Marakwet and Endo (together 30,000), Sabaot, Pok and Kony (in all 24,000), all of whom live in north and central Kenya, and the Sebei (24,000) on the northern slopes of Mount Elgon in Uganda. Far to the south in Tanganyika are the Tatoga and Barabaig (64,000). Except for these last, all Nandi tribes have adopted agriculture, the Marakwet-Endo, Keyo and some Pokot having complex irrigation works; the Nandi and Kipsigis especially are highly progressive farmers. The Masai (*q.v.*) speakers include the Masai of the rift valley, in both Kenya and Tanganyika (180,000), the Arusha of northern Tanganyika (63,000) and the Samburu (22,000), Njemps (Njemusi) and others of northern Kenya who are really to be counted as outlying Masai tribes; the Baraguyu or Kwavi of central Tanganyika are dispersed across a wide region living in small communities amid settled Bantu tribes; they number 20,000, and are often considered to be Masai. All the Masai speakers wholly or mainly depend on pastoralism. *See* also AFRICA: *Ethnography* (*Anthropology*): *Northeast Africa* and *East Africa;* DIDINGA; LOTUKO.

NILOTES, a number of east-central African tribes living in the southern Sudan and north Uganda and extending into neighbouring territories. The name refers to their habitat, mostly the region of the upper Nile and its tributaries, and to a linguistic unity that distinguishes them from Nilo-Hamitic neighbours with similar physique and culture (*see* NILO-HAMITES).

Four subdivisions of the Nilotic languages are generally recognized: the closely related languages of the Dinka and Nuer (*qq.v.*); the northern Lwoo languages spoken by such groups as the Shilluk, Anuak, Burun, Maban, Jo Luo, Thuri and Bor, and the southern Lwoo languages of the Acholi, Lango (*q.v.*), Alur, Jopadhola, Ja Luo and lesser known groups. Nilotic languages are closely related to the Nilo-Hamitic languages, particularly in vocabulary, but their affinities in a wider classification of African languages are obscure and there is considerable disagreement in the literature (*see* AFRICAN LANGUAGES).

The genetic origins of the Nilotes are likewise uncertain and disputed. A mixture of Hamitic and Negro ethnotypes in the ancestry is a basic assumption. Blood group studies suggest that a very high frequency of the Rh chromosome, cDe, may be a special Nilotic character. There is considerable genetic divergence between the northern and southern groups both in ABO blood group frequency and the presence of the sickle-cell trait. Nilotes tend to be dolichocephalic with frizzy hair and dark complexion; northern Nilotes are tallest (average 1.78 m., or 5 ft. 10 in.) with slender build. They have been said to show proud, individualistic and aggressive behaviour, scorn for foreigners and dislike of innovation. Although a distinctive ethnic group, Nilotic tribes vary in culture and exceptions to any generalization can be found among one or more tribes. The southern Luo (*q.v.*) tribes in particular are divergent because of admixture with Nilo-Hamitic and Bantu neighbours.

Men and unmarried girls traditionally go naked, except for ornaments; a skin cloak is sometimes knotted over the shoulder. Married women usually wear leather aprons back and front, suspended from the waist. Cicatrization and the extraction of lower incisor teeth have been common; the forehead is often scarred. Elaborate hair styles are produced with grease and cattle dung and the body is sometimes coated with ashes. Material culture is poor, although the Jo Luo were noted ironworkers.

Most Nilotes occupy savanna country alternately subject to flooding and drought. They pursue a mixed economy of pastoralism and hoe cultivation, supplemented by fishing, hunting and a little food gathering. Although they may cultivate out of necessity, except for the Anuak, they are pastoralists with a great love of cattle; cattle enter into every aspect of society. Milk and milk products, with grain, are staple foods. Cattle are not slaughtered indiscriminately for meat; they are paid in compensation and bride wealth, and their ownership determines status and wealth. Nilotic peoples have a rich cattle vocabulary; they spend much time caring for the herds and erecting large stables or kraals for their protection. It is common for a man to train and decorate the horns of his favourite ox, and in many cases he is addressed by the animal's name. Cattle assume ritual importance, being dedicated and sacrificed to ancestors or spirits.

Nomadic or transhumant movements are especially pronounced among the Nuer and Dinka. In the wet season they live in permanent village settlements above flood level and cultivate and herd in the vicinity of well-built, circular houses. In the dry season they occupy temporary cattle camps near permanent water supplies and pasture, living in windbreaks, for fishing and herding. Other Nilotic tribes are more sedentary.

The Shilluk are the most highly organized, having a divine king who symbolizes the whole realm. Organized chieftainships, associated with rainmaking, court ceremonial and royal emblems, are found also among the Anuak, Acholi and others. In contrast, the Nuer, Dinka and Luo of Kenya are classified as tribes without rulers, their egalitarian society being based on a relationship between lineage segments co-ordinated with territorial segments. A dominant clan is associated with a tribal territory; dominant lineages of this clan are found in subdivisions of the tribe. The principle of opposition between segments and their fusion in relation to larger segments is marked; descent is patrilineal.

Ritual experts are often rainmakers; among the Dinka and Nuer they act also as mediators and peacemakers in feuds between lineages and between territorial subdivisions. There are strong ancestor cults and belief in a supreme being. Totemism exists in some tribes but is important only among the Dinka. *See* also AFRICA: *Ethnography* (*Anthropology*); NEGRO; KAVIRONDO.

NIMAR, East and West, are two districts in the Indore administrative division, southwest Madhya Pradesh, India.

EAST NIMAR (area 4,132 sq.mi.; pop. [1961] 685,150) forms a "bridge" nearly 50 mi. wide between the Narmada (Narbada) river and the Vindhya mountains in the north and the Tapti river and the Satpura range in the south. Forest covers 44% of the area. The principal crops are jowar, cotton, rice and peanuts. A thermal power station at Chandni serves the western parts of the district. There are a cotton textile mill and a paper and straw mill at Nepanagar. The district headquarters are at Khandwa (*q.v.*), a railway junction on the Central railway. Burhanpur (*q.v.*), a textile trade centre, was the Deccan headquarters of the Mogul empire (1559–1636). At Mandhata (*q.v.*), 31 mi. N.W. of Khandwa, are noted Hindu temples.

WEST NIMAR (area 5,206 sq.mi.; pop. [1961] 990,464) extends from the Satpura range to the Narmada valley. The valley portion has fertile lava soil but the rest is broken by spurs of the Satpura range. Bijagarh fort (25 mi. S.W. of Khargone) is of historical interest. Of the total area 57% is arable and 12% forested. The chief crops are jowar, wheat, rice, cotton and peanuts. Large-scale industries are lacking, but there are numerous medium- and small-scale factories in the district. Maheshwar has some handlooms and a match factory. The district headquarters are at Khargone (pop. [1961] 30,652), which lies 35 mi. E. of Jalwania, a town on the Indore-Bombay road. Khargone became important under the Moguls, when it was the chief town of a mahal (revenue division) and then of the Bijagarh sircar, or sarkar (administrative district), under Akbar. (S. M. A.)

NIMBUS: *see* GLORY.

NÎMES, a town of southern France, capital of the *département* of Gard and seat of a bishopric, lies 267 km. (166 mi.) S.S.W. of Lyons by road, between Avignon and Montpellier. It is also connected by rail with the Paris-Lyons-Marseilles line and with Clermont-Ferrand. Pop. (1962) 85,884.

Nîmes lies at the foot of the Monts Garrigues, a chain of barren hills to the north and west. The highest of them is the Mont Cavalier on the summit of which stands the Tour Magne (Turris Magna), a ruined Roman tower. To the south and east the town dominates the plain of the Vistre brook, which is largely covered with vines. The central and oldest part of the town is encircled by boulevards along the sites of the old fortifications. It is there that most of the Roman remains, for which Nîmes is celebrated, are to be found. The most famous is the amphitheatre (Les Arènes) which is the best-preserved in France. It dates from the 1st or 2nd century A.D. and was used as a fortress at various times during the succeeding centuries. During the middle ages it was a separate quarter of the town with its own church; it was cleared in 1809. It is built of large stones put together without mortar and forms an ellipse with external measurements of about 440 by 330 ft. The arena is 227 by 126½ ft. The elevation (70 ft. in all) is composed of a ground floor with 60 arches, an upper floor, also with 60 arches, and an attic with corbels pierced with holes, to keep up the *velarium* or awning. The building, which holds 24,000 people, has four main entrances, one at each of the cardinal points, and 124 exits which lead from the 35 rows of the amphitheatre into the interior galleries. The arena was originally intended for gladiatorial shows, naval spectacles, chariot races and wolf or boar hunts, and for some time has been used for bullfights.

The famous Maison Carrée, a Roman temple 82 ft. long by 40 ft. wide, was dedicated, according to an inscription, to Gaius and Lucius Caesar, adopted sons of Augustus, and dates from the beginning of the Christian era. It houses a collection of sculpture and classical fragments. The temple of Diana, near the Fountain garden (Jardin de la Fontaine), was certainly attached to the baths, the remains of which are visible nearby. Two Roman gateways, the Porte d'Auguste, formed of two main arches flanked by two smaller ones and dating from A.D. 16, and the Porte de France, still stand. The Tour Magne is 92 ft. high and was once higher. It is the oldest monument in Nîmes, but its original function is not known. It was used as a watchtower and was subsequently turned into a fortress by the counts of Toulouse in the middle ages. Near the Tour Magne is the reservoir from which the water carried by the Roman aqueduct, Pont du Gard, was distributed throughout the town. With its status as a capital, and with the temple of Augustus, the basilica of Plotina (erected under Hadrian), the temple of Apollo, the pools, the theatre and the circus (erected in Nero's reign), the Campus Martius and the fortifications of Augustus, Nîmes must have been one of the richest Roman towns in Gaul.

The cathedral (St. Castor) which is thought to occupy the site of the temple of Augustus, is partly Romanesque and partly Gothic in style; the churches of St. Paul and St. Baudile are modern; the Fountain gardens owe their name to a spring which varies considerably in volume and flows into the Vistre; the town's water comes from the Rhône. The novelist Alphonse Daudet (1840–1897) and the Provençal poet Jean Reboul (1796–1864) were natives of the town. It is the seat of a bishopric (under the archbishop of Avignon), a prefect, a court of appeal, an assize court, county courts and commercial courts and a chamber of commerce.

At the end of the middle ages the crafts of Nîmes, which derived fresh energy from the arrival of a colony from Lombardy and Tuscany, preserved their importance so well that before the Revolution about half the total community was engaged in manufacture, chiefly of products derived from silk. Woven cloths,

shawls, carpets, handkerchiefs, ribbons and braids, clothes, boots and shoes, brandy, leather goods, candles and machinery are now manufactured there, and there are some foundries. Nîmes also has an important trade in wine and brandy, grain, groceries and overseas produce. Limestone quarries which supplied the amphitheatre and other buildings are still worked in the vicinity.

Nîmes, the ancient Nemausus, was so called after the sacred wood in which the Volcae Arecomici (who submitted to Rome in 121 B.C.) held their assemblies. Strabo asserts that it was the capital of a region containing 24 vassal towns and was independent of the proconsuls of Gallia Narbonensis and that it was established as a veterans' college by Augustus and endowed with numerous privileges. The town erected a temple and struck a medal in honour of its founder. The medal, which later furnished the design for the armorial bearings granted to the town by Francis I, bears on one face the heads of Caesar Augustus and Marcus Vipsanius Agrippa (Augustus' head is crowned with laurel) and on the other a crocodile tied to a palm tree (suggesting that the original settlers were veterans of the Roman Egyptian army), with the legend COL NEM (Colonia Nemausis). Agrippa built the public baths, the temple of Diana and the Pont du Gard. The walls (built by Augustus), 30 ft. high and 10 ft. broad, extended for almost 4 mi. in circuit, flanked by 90 towers and pierced by 10 gates. Hadrian erected two monuments of his benefactress Plotina at Nîmes. At the height of its prosperity the town was ravaged by the Vandals (407); the Visigoths followed (720) and turned the amphitheatre into a fortress which at a later date was burned with the town gates when Charles Martel drove out the Saracens. Nîmes became a republic under the protection of Pippin the Short. In 1185 it passed to the counts of Toulouse who enclosed the town with ramparts less vast than those of Augustus (which became part of the boulevards). The town took part in the crusade against the Albigenses in the early 13th century. In the reign of Louis VIII it housed a garrison of the king's soldiers in the amphitheatre; under Louis XI it was taken by the duke of Burgundy and retaken by the dauphin (Charles VII) in 1420. On a visit to Nîmes, Francis I enriched the town with a university and an art school. By 1558 about three-fourths of the inhabitants had become Protestants and on Sept. 29, 1567 (St. Michael's day), there was a massacre of Catholics. From the time of Henry IV's accession to the throne until the revocation of the Edict of Nantes (1685) the Protestant community was active in industry; but after this disastrous event a great number of Protestants went into exile or joined the Camisards. Louis XIV built a fortress (1687) to halt the disturbances caused by the rival religious sects. Nîmes emerged unscathed from the troubles of the Revolution, but in 1815 Trestaillons and his bandits burned the town and massacred Bonapartists and Protestants.

NIMITZ, CHESTER WILLIAM (1885–1966), U.S. naval officer, commander of the U.S. Pacific fleet in World War II, was born in Fredericksburg, Tex., on Feb. 24, 1885. He graduated from the U.S. Naval Academy, Annapolis, Md., in 1905, and during World War I served as chief of staff to the commander, U.S. Atlantic submarine force. Appointed chief of the Bureau of Navigation of the U.S. Navy in 1939, he became commander in chief of the Pacific fleet following the Japanese attack on Pearl Harbor in December 1941.

Nimitz' command of the Pacific Ocean areas, with headquarters at Pearl Harbor, complemented the Southwest Pacific area command of Gen. Douglas MacArthur and brought land as well as naval forces under his authority. Under his direction and that of his subordinates, Admirals William F. Halsey, Marc A. Mitscher, Richmond K. Turner, Raymond A. Spruance, and Thomas C. Kinkaid, were fought the Battles of Midway (1942); the Solomons (1942–43); the Gilbert Islands (1943); the Marshalls, Marianas, Palaus, and Philippines (1944); and Iwo Jima and Okinawa (1945). Nimitz participated for the United States in the Japanese surrender aboard his flagship, the USS "Missouri," in Tokyo Bay on Sept. 2, 1945. (*See* WORLD WAR II: *The War in the Pacific*.) In December 1944 he had been promoted to the Navy's newest and highest rank—fleet admiral. After the war he served for two years as chief of naval operations (December 1945–December 1947). In 1947, in answer to interrogatories by German Adm. Karl Dönitz, on trial for war crimes, Nimitz gave his justification for the unrestricted nature of U.S. submarine warfare in the Pacific during World War II. He did not write memoirs but collaborated with E. B. Potter in editing *Sea Power a Naval history* (1960). Nimitz died near San Francisco, Calif., on Feb. 20, 1966.

NIMROD (in the Douai version of the Bible, NEMROD) is described in Gen. x, 8–12 as "the first on earth to be a mighty man. He was a mighty hunter before the Lord." Apart from I Chron. i, 10, which quotes this description, the only other reference to Nimrod in the Old Testament is Mic. v, 6, where Assyria is called the land of Nimrod. Unlike the other names in the Genesis context which are names of people, Nimrod is that of an individual. The beginning of his kingdom is said in Genesis to be Babel, Erech and Akkad in the land of Shinar. Babel is Babylon; Erech is an ancient Sumerian city of Mesopotamia (Uruk, Orchoë, modern Warka, in southeastern Iraq); and Akkad (Agade), the royal city of Sargon I, was the capital of a district of the same name in Mesopotamia. Shinar, which the Old Testament sometimes identifies with Babylonia, was, as Egyptian and Hittite records show, a distinct country, probably in northern Mesopotamia, which was prominent *c.* 1500–1200 B.C. Nimrod is said to have built Nineveh, Calah (modern Nimrud; an old Assyrian town on the left bank of the Tigris, south of Nineveh), Rehoboth-Ir and Resen, the latter two unknown. It is in accordance with historical truth that Assyria was developed from Babylonia. The description of Nimrod as a "mighty hunter before the Lord" is an intrusion in this context, but probably, like the historical notices, derived from some old Babylonian saga; the Assyrian kings were noted for their prowess in hunting.

Though one may feel reasonably sure that the Nimrod traditions were derived from Babylonian sources, no equivalent of the name has yet been found in the cuneiform records. In character there is a certain resemblance between Nimrod and the hero Gilgamesh (*q.v.*). (W. L. W.; X.)

NIMRUD, the modern name of the site of the ancient Assyrian city of CALAH (KALHU, KALAKH). Calah was situated on the east bank of the Tigris about 22 mi. S. of ancient Nineveh and of modern Mosul (in Iraq). The city was first excavated by A. H. Layard during 1845–51 and afterward principally by M. E. L. Mallowan during 1949–58 on behalf of the British School of Archaeology in Iraq; he was assisted by David Oates, who became field director in 1958. Founded by Shalmaneser I in the 13th century B.C., Calah remained unimportant until King Ashurnasirpal II (883–859 B.C.) decided to make it his royal seat and the military capital of Assyria. He spent the first five years of his reign building the Acropolis; within it were concentrated his palace, the principal temples and the ziggurat which was dedicated to Ninurta, god of war and the chase, patron of the city. The famous northwest palace was decorated with gypsum bas-reliefs which depicted the king's military triumphs and the magical genii protective figures who guarded his person. In addition to the Acropolis, which covered about 65 ac. of ground, there was an outer walled town, and the whole city was nearly 900 ac. in area.

The work begun on Calah by Ashurnasirpal II was completed by his son Shalmaneser III and other monarchs; Adad-nirari III, Tiglath-pileser III and Esarhaddon added palaces of their own. The most important religious building, founded in 798 B.C. by Queen Sammu-ramat (Semiramis of Greek fame), was Ezida, which included the temple of Nebo (Nabu), god of writing, and of his consort Tashmetum (Tashmit). The ancient library discovered within it contained many religious and magical texts, and in an annex to the building a throne-room, occupied by Esarhaddon, produced tablets which embodied "treaties" ratified in the year 672 B.C. Incorporated within these documents was the last will and testament of the king of Assyria. Several paragraphs clearly defined the succession: his son Ashurbanipal, to be king after him in Assyria, and Shamash-shum-ukin in Babylon. Many other documents were also found. Of the buildings in the outer town the most important is Fort Shalmaneser, an arsenal which occupied at least 12 ac. of ground. This and other buildings have yielded

thousands of carved ivories, mostly made in the 9th and 8th centuries B.C., now the richest collection of ivory in the world. The technique of cutting and the sensitive artistry display the astonishing level of craftsmanship which had been achieved after generations of experiment in Syrian, Phoenician and Assyrian workshops. Of these pieces perhaps the most famous are the ivory head known as the Mona Lisa and a pair of chryselephantine plaques depicting a lioness killing a Negro against a background of papyrus and lilies which are incrusted with carnelian and lapis lazuli and overlaid with gold.

In the 7th century B.C. Calah declined in importance, for the Sargonids tended to use Nineveh as their residence, but nonetheless the place continued to be extensively occupied down to the fall of Nineveh in 612 B.C., Calah having previously been sacked in the year 614. Perhaps the most interesting historical record unearthed in the city was a sandstone stela of King Ashurnasirpal II which celebrated the opening of the city in the fifth year of his reign and gave a list of the important buildings, gardens and irrigation schemes, as well as of the flora and fauna which he had acquired, and finally recorded a feast which he gave to 69,574 persons over a period of ten days. The menu was written down in detail.

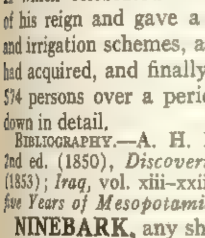
NINEBARK, any shrub of the genus *Physocarpus* of the rose family (Rosaceae). One of the best known is *P. opulifolius*, with oval or roundish leaves, native from Quebec to Minnesota, south to South Carolina and Colorado, and commonly planted for ornament. It grows from five to ten feet high, with strong, recurving stems, shedding bark and small, white or pinkish flowers, in umbellate clusters, followed by clustered, inflated, reddish follicles. There are variegated and dwarf varieties. *P. monogynus*, of the western U.S., is shorter and has somewhat kidney-shaped leaves.

NINE MEN'S MORRIS, a game played with counters on a board, also known as Muhle (Germany and Austria), Marelle (France), Mylla (Iceland), Siegen Wulf Myll (Poland) and The Mill, Morelles, Merry Peg, etc., in England.

The board (*see* diagram) comprises three concentric squares and several transversals, making 24 points of intersection. Two players, each provided with nine counters of his own colour, lay pieces alternately upon the points, the object being to get three in a row upon any line. On doing so, the player is entitled to remove from the board one adverse counter, but not one that is in a "mill," a row of three. Having placed all their counters, the players continue moving alternately, with the same object. A "mill" may be opened by moving one piece off the line; returning the piece to its original squares counts as a new "mill." The player who first captures all the adverse pieces wins. A move is limited from one point to the next along a line, but the rule is often made that when a player has only three pieces left he may move them from any point to any point regardless of the lines. In modern play the diagonal lines of the board are usually omitted, to lessen the advantage of the first player.



THE MILL BOARD
In modern play the diagonal lines are usually omitted

The mill game was often played by shepherds with stones upon a diagram cut into the turf. Shakespeare alludes to this practice in *A Midsummer Night's Dream* (act ii, scene i):

> The nine men's morris is fill'd up with mud,
> And the quaint mazes in the wanton green
> For lack of tread are indistinguishable.

"Morris" (*i.e.*, Moorish) is the name of a square dance to which the game bears a fanciful resemblance. (G. MH.; X).

NINETEENTH-CENTURY ARCHITECTURE: *see* MODERN ARCHITECTURE.

NINETEENTH-CENTURY ART. The 19th century was remarkable for a medley of artistic styles and attitudes. If the broad tendencies can be loosely contained within the categories of classicism and romanticism, the characteristic spirit which informed the significant art of the whole century was a militant and creative individuality.

Classicism.—In the opening years, the classical tendency was in the ascendant. In France, out of the Revolution, came a rigid and conscientious neoclassicism with J. L. David as its chief exponent. This resurgence was, on the one hand, the culmination of a prevailing vogue for Greek and Roman antiquities and, on the other, an active repudiation of the Arcadian frivolities of rococo. At the same time, neoclassical pictures fulfilled the purpose of Revolutionary propaganda by relating the solid virtues of republican Rome with those of the new republic of France. When Napoleon became emperor in 1804, David was designated first painter and the concept of imperial majesty, ever present in the emperor's mind, became David's ruling obsession. His influence was decisive, not only in painting, but in the formulation of appropriate styles of décor and furniture, of which the so-called Empire style became popular throughout Europe and even in the United States. (*See* NEOCLASSICAL ART.)

In architecture, Napoleon's hankerings for Roman grandeur, satisfied by the work of P. F. L. Fontaine and C. Percier, were consummated in J. F. Chalgrin's design for the Arc de Triomphe de l'Étoile. For the most part, however, the 19th century's attempts to create a style consisted of quotations from the Greek. In Germany the Greek revival was a wholehearted and enthusiastic movement which produced some distinguished classical adaptations by L. von Klenze and K. F. Schinkel. In England, Sir John Soane's Bank of England had commendable originality and John Nash created an *architecture parlante*, a style for every occasion, classical for the Regent's park and Regent street frontages, Hindu for Brighton pavilion, Gothic for his own country house. (*See* MODERN ARCHITECTURE.)

Romanticism.—David's direction was generally sustained by his pupils J. A. D. Ingres, A. L. Girodet-Trioson, F. Gérard and A. J. Gros, but with the fall of Napoleon, David was exiled. The neoclassical movement, deprived of both leadership and propagandist significance, was confronted with fiercely critical attacks by the romanticists on the grounds that it was sterile and repetitive. By the end of the first quarter of the century, romanticism had spread through Europe like an epidemic, emerging as a reaction from the repressive nature of 18th-century rationalism. As such, it offered an escape for the emotion from an insistent cult of reason and a release for the personality from disciplined compliance with convention. The first aim of the romantic artist was self-expression and his typical expression tended to be evocative of more than it stated. The movement, literary in origin and character, exploited a repertoire of constantly recurring themes, such as the feelings of the artist in the presence of nature, nostalgia for an irretrievable past, the whole gamut of emotional states and every aspect of liberty. In England, romanticism was innocently present in the verse and graphic work of William Blake, dramatically apparent in the apocalyptic visions of John Martin and the macabre nightmares of Henry Fuseli, gently appealing in the Shoreham period (1826–35) of Samuel Palmer. In Germany, there were the brilliant romantic writings of Friedrich von Schlegel, the folklore researches of Jacob and Wilhelm Grimm, and the pictures of K. F. Schinkel, C. D. Friedrich and P. O. Runge. In France, J. L. A. T. Géricault depicted the terror, pity and horror of the wreck of the frigate "Medusa" and E. Delacroix glorified freedom and expressed wide-eyed admiration for Lord Byron in his "Massacre at Chios."

Toward the middle of the century the Gothic style revived with more animation in England than elsewhere. Victorian Gothic was a romantic expression both of a partiality for medievalism and of a revulsion from an insistent and pervasive industrialism. John Ruskin, its advocate, genuinely believed that the Gothic style would be an inspiring liberation from the enslavement of classical traditions. Yet its revival was only further proof that architectural design had become an incoherent sham. Industrial design exemplified by the Great exhibition of 1851 had reached its nadir (*see* DESIGN, 19TH-CENTURY). Artists like the Pre-Raphaelites

attempted to escape from the hideous present. Others sought self-justification in the comfortable theory of art for art's sake. William Morris witnessed their withdrawal. A hater of machinery, he maintained that the artist must once again become a craftsman and the craftsman an artist, that art must be made by and for the people. "What business have we with art at all," he asked, "unless all can share it?" (*See* Arts and Crafts Movement). However, the absence of any organized patronage had given rise to the 19th-century notion of the artist inevitably in conflict with his own age. With no specific social function, the painter worked prophetlike in isolation. The general public were his patrons; the salons and academies, each dictating their own preferences and prejudices, were his showrooms. The tremendous popularity of works by Sir David Wilkie, Sir Edwin H. Landseer and W. P. Frith was indicative of the average level of appreciation.

Realism.—The classical and romantic movements had one area of common ground: both were idealist in their refusal to accept the world as they found it. Midway between both, a realist tendency was in evidence throughout the 19th century. Goya, with his uncompromising assessments of man and his behaviour, was its starting point. His unflinching observation was later matched by that of H. Daumier, who invested the capacity with a kindlier derisiveness. Last of the great realists was G. Courbet, who chose to paint only what he could see and what he saw was the rich variety of his immediate world.

Impressionism.—The final significant movement of the 19th-century was Impressionism and the approach to Impressionism was by way of landscape painting. Early in the century, J. M. W. Turner and J. Constable had anticipated the work of J. B. C. Corot and the Barbizon school by a wholly new conception of landscape painted in the open air and based on natural vision. Impressionism was the direct consequence of this innovation. Of the Impressionists, C. Monet was unique in pursuing his analysis of colour and light to its furthest conclusions. P. Cézanne's comment, "Monet is only an eye. But, my God, what an eye!" was a shrewd summary of the Impressionists' shortcomings and achievements. But, by the 1880s, the very brilliance of their accomplishment had pushed representational painting into a cul-de-sac along which progress seemed impossible. Furthermore, the development of photography had undermined any assumption that the future of painting would be concerned with the imitation of appearances. The response to this situation emerged in Cézanne's methodical "constructions after nature," in the acutely personal romanticism of V. Van Gogh and the decorative symbolism of P. Gauguin. At the close of the century, largely on the foundation of their work, the modern movement began and developed. *See* also Painting; Sculpture.

NINEVEH, the most populous and the oldest city in Assyria, lay on the east bank of the Tigris opposite modern Mosul (in Iraq). From time immemorial, roads from the foothills of Kurdistan debouched there, and a tributary of the Tigris, the river Khawsar, added to the value of the fertile agricultural and pastoral lands in the district. The first to survey and map Nineveh was C. J. Rich in 1820, a work later completed by Felix Jones and published by him in 1854. Excavations have been undertaken intermittently since that period by many persons. A. H. Layard during 1845–51 discovered the palace of Sennacherib and took back to England an unrivaled collection of stone bas-reliefs together with thousands of tablets inscribed in cuneiform from the great library of Ashurbanipal II. Hormuzd Rassam continued the work in 1852. During 1929–32 Campbell Thompson excavated the temple of Nebo (Nabu) on behalf of the British museum and discovered the site of the palace of Ashurnasirpal. In 1931–32 together with M. E. L. Mallowan, he made a sounding for the first time from the top of the acropolis (Quyunjik), 90 ft. above the level of the plain down to virgin soil. It was then proved that over four-fifths of this great accumulation is prehistoric.

The first settlement, a small Neolithic hamlet, was probably founded not later than the 6th millennium B.C. An obsidian blade industry suggests that there was contact with Van in eastern Armenia from the beginning. Samarran and Halaf painted pottery of the subsequent Early Chalcolithic phases, characteristic of the north, was succeeded by gray wares such as occur westward in the Jebel Sinjar. In the course of this period the farmers used clay sickles of a type found in the 'Ubaid period, and these implements imply contact with the south. A little before and after 3000 B.C. unpainted Ninevite pottery was similar to that used in Sumerian cities such as Ur and Erech. At Nineveh a number of large mud-brick burial vaults, unfortunately plundered, up to nine feet in height, suggest that the city was rich in Early Dynastic times; thousands of beads similar in type to hoards found in tombs in the neighbouring site of Tepe Gawrah were probably associated with the Ninevite burials. The most remarkable object of the 3rd millennium B.C., however, is a realistic bronze head, life-size, cast and chased, of a bearded monarch. It is probable that this, the finest piece of metal sculpture ever to be recovered from Mesopotamia, may represent the famous King Sargon of Agade, *c.* 2350 B.C.

Surprisingly, there is no large body of evidence to show that Assyrian monarchs built at all extensively in Nineveh during the 2nd millennium B.C., certainly not during the four centuries that succeeded Shamshi-Adad I when Assyria was of little account owing to the power of the superior Hittite, Kassite and Mitannian dynasties. An interesting historical document however describes a victorious campaign of Ashur-uballit I (1365–30 B.C.) against a Kassite usurper, during a period of Assyrian renascence. The fame of Ishtar of Nineveh had indeed reached the ears of the Pharaoh before that, for her statue was sent to Egypt by Tushratta, king of Mitanni, in order to restore his health. Later monarchs whose inscriptions have appeared on the acropolis include Shalmaneser I (1275–45 B.C.) and Tiglath-pileser I, both of whom were active builders in Ashur; the former had founded Calah (Nimrud). But Nineveh had to wait for the neo-Assyrians, particularly from the time of Ashurnasirpal II onward, for a considerable architectural expansion. Thereafter successive monarchs kept in repair and founded new palaces, temples to Sin, Nergal, Nanna, Shamash, Ishtar and Nebo (Nabu). Unfortunately owing to severe depredation little remains of these edifices.

It was Sennacherib who made Nineveh a truly magnificent city laid out fresh streets and squares and built within it the famous "palace without a rival," the plan of which has been mostly recovered and has overall the dimensions of about 600 by 630 ft. It comprised at least 80 rooms, of which many were lined with sculpture. A large part of the famous "K" collection of tablets was found there; some of the principal doorways were flanked by human-headed bulls. At this time the total area of Nineveh comprised about 1,800 ac., and there were 18 great gates which penetrated its defensive walls. An elaborate system of 18 canals brought water from the hills to Nineveh, and several sections of a magnificently constructed aqueduct erected by the same monarch were discovered at Jerwan about 25 mi. distant.

His successor Esarhaddon built an arsenal in the Nebi Yunus south of Quyunjik, and either he or his successor set up at its entrance as trophies statues of the Pharaoh Taharqa (Tarku) to celebrate the conquest of Egypt. These were discovered by Fuad Safar and Mohammed Ali on behalf of the Iraq antiquities department in 1954.

Ashurbanipal constructed a new palace at the northwest end of the acropolis. It was this king who founded the great library and ordered his scribes to collect and copy ancient texts throughout the country. The "K" collection included over 20,000 tablets or fragments of tablets and incorporated the ancient lore of Mesopotamia. The subjects are literary, religious, administrative, and

there are large numbers of letters. Various branches of learning represented include mathematics, botany, chemistry and lexical texts. The library in fact is still a mass of information about the ancient world and will exercise scholars for many generations to come. (*See* also BABYLONIA AND ASSYRIA: *Language and Literature.*) Extensive traces of ash which represent the sack of the city by Babylonians, Scythians and Medes in 612 B.C. have been observed in many parts of the acropolis. Thereafter the city ceased to be important, although there are some Seleucid and Greek remains. Xenophon in the *Anabasis* recorded the name of the city as Mespila. In the 13th century A.D. the city seems to have enjoyed some prosperity under the atabegs of Mosul. Subsequently houses continued to be inhabited at least as late as the 16th century A.D. In these later levels imitations of Chinese wares have been found.

NINGPO (formerly Yin Hsien or Ninghsien), the name of a district and of its administrative seat, commonly called Ning-po shih (city), an important port near the mouth of Hangchow bay in northeastern Chekiang province of China. The city (pop. [1953] 237,500) is about 12 mi. above the mouth of the Yung Chiang at the confluence of the Feng-hua and Yuyao tributaries. The old walled city lies between these, but suburbs have been built across both tributaries which are bridged. Hills rise in back of the fertile plain in which the city is situated. The river is navigable to vessels up to 20 ft. draft and 350 ft. length as far as the anchorage opposite Ningpo. The old foreign settlement was situated on the left bank of the Yung Chiang across the Yuyao from the walled city. Chenhai is an outport for Ningpo at the mouth of the Yung and is protected from sea storms by Tinghai and other islands.

Ningpo is an ancient seat of learning and Buddhist religion. It has occupied its present site since A.D. 713 and was one of the earliest sites of European settlement in China. The Portuguese arrived there in 1520, but were driven out by the Chinese 25 years later because of their illegal activities. Subsequent restrictions made foreign trade with Ningpo virtually impossible. During the Chinese-British war of 1840–42, British warships blockaded Ningpo, but in 1842 the treaty of Nanking opened the port to foreign trade. However, the superior situation of Shanghai at the gateway to the Yangtze valley greatly restricted Ningpo's commercial hinterland. On the seaward side, Ningpo acts as the market centre for the Chou-shan Islands, and a national fish market was established at Ningpo in the 1950s for the productive sea fisheries in the area. After the outbreak of the Chinese-Japanese war in 1937 Ningpo was one of the few ports to remain open until after 1940. The city exports cotton grown in neighbouring districts; other products shipped include native drugs, tea, reed mats and fish, most of these going to Shanghai. Ningpo imports large quantities of sugar, largely from Fukien province, and textiles and other manufactures from Shanghai. It has some foreign trade but its domestic trade is far more important. Ningpo manufactures cotton and silk yarns and cloth, electrical supplies, canned goods, knitwear, candles and soap. The city has canal, railroad and highway connections with Hangchow in the west. The railroad was destroyed during World War II, but restored in 1955, and extended about 25 mi. E. to the town of Ts'ai-ch'iao. A highway leads southward to Chekiang coastal towns. (H. J. Ws.)

NINGSIA (NINGHSIA), former province of China, in western Inner Mongolia. Upon its abolition in 1954, the province was merged with Kansu (*q.v.*). In 1956, most of former Ningsia, settled by Mongols, passed to the Inner Mongolian Autonomous Region (Nei Mengku Tzu-chih Ch'u). The rest of former Ningsia, inhabited largely by Hui (Chinese Muslims), was constituted in 1958 as the Ningsia Hui Autonomous Region, equivalent to a province (capital, Yinchwan; area 30,039 sq.mi.; pop. [1958 est.] 1,822,000, of whom one-third were Chinese Muslims). *See* also MONGOLIA, INNER. (T. SD.)

NINIAN (NINIAS, RIGNA, TRIGNAN), **SAINT,** early British bishop of the church known as Candida Casa (at Whithorn, Scot.), was the first to preach Christianity among the southern Picts. He lived before the missionary activities of St. Columba, who arrived from Ireland about 563. Some scholars, misunderstanding a phrase in the authentic writings of St. Patrick, placed Ninian's career in the last years of the 4th century and stated that he had dedicated his church to the memory of Martin of Tours on hearing of the latter's death (397), which is impossible, as there were then no dedications of churches except in honour of a martyr. The idea of Ninian's having trained in Rome, though found already in Bede's ecclesiastical history, is almost certainly imaginative propaganda from the Anglian clergy, who had then recently replaced the Celtic churchmen in the present Wigtownshire. Ninian later became a principal patron in Scotland. His feast day is Sept. 16.

BIBLIOGRAPHY.—A. B. Scott, *St. Ninian, Apostle of the Britons and the Picts* (1916); W. D. Simpson, *Saint Ninian and the Origins of the Christian Church in Scotland* (1940). For a critical assessment of the legend *see* P. Grosjean, "Les Pictes apostats dans l'Épitre de S. Patrice," *Analecta Bollandiana*, vol. 76 (1958). (PL. GN.)

NINO (NINA), **SAINT** (fl. *c.* A.D. 330), a holy woman who converted the Iberians (Georgians) of the Caucasus to Christianity during the reign of Constantine the Great. The earliest account of her apostolate stems from the church historian Rufinus, who evidently heard it from a Georgian prince. Nino was a captive woman, who cured a sick child by the power of prayer, and then healed the Georgian queen. The king was later convinced of the truth of her preaching by an eclipse of the sun, which plunged him and his followers into dense murk, until he thought of appealing to the God of Nino. A church was erected at the old Iberian capital of Mtskheta; its main pillar was raised into position by supernatural agency. These events are supposed to have taken place *c.* A.D. 330.

The story of St. Nino has since been overlaid with fabulous embellishments, some of them anachronistic, including the miraculous destruction of the Georgian pagan idols. Nino is represented in later Georgian tradition as niece of the patriarch Juvenal of Jerusalem (d. 458), and as a companion of the holy Ripsime and her company of virgins, martyred by the Armenian king Tiridates III (d. 330). The shrine of St. Nino is at Bodbe in Kakhetia (now part of the Georgian Soviet Socialist Republic); her feast day is Jan. 14 in the Georgian Orthodox Church and Dec. 15 in the Roman Catholic Church.

See D. M. Lang, *Lives and Legends of the Georgian Saints* (1956). (D. M. LA.)

NINUS, in Greek mythology, the eponymous founder of the city of Nineveh; also the name of the city itself. He was said to have been the son of Belos or Bel; to have conquered in 17 years the whole of western Asia with the help of Ariaeus, king of Arabia; and to have founded the first empire. During the siege of Bactra he met Semiramis, the wife of one of his officers, Onnes, whom he took from her husband and married. The fruit of the marriage was Ninyas; *i.e.*, "the Ninevite." After the death of Ninus, Semiramis, who was accused of causing it, erected to him a temple tomb nine stades high and ten stades broad near Babylon. The legendary aspects of this story were disproved in 1910. For the historical aspects, *see* SEMIRAMIS.

Another Ninus is described by some authorities as the last king of Nineveh, successor of Sardanapalus.

NIOBE, in Greek mythology, the daughter of Tantalus and wife of King Amphion of Thebes, is the typical sorrowful woman, weeping for the loss of all her children. According to the *Iliad* she had six sons and six daughters and boasted of her superiority in this respect to the Titaness Leto (*q.v.*), who had only two children, the twin deities Apollo and Artemis. As punishment for her pride Apollo killed all Niobe's sons and Artemis killed all her daughters. The bodies lay for nine days unburied because Zeus had turned all the Thebans to stone, but on the tenth day they were buried by the gods. Niobe went back to her Phrygian home, where she was turned into a rock on Mt. Sipylus (Yamanlar Dag, northeast of Izmir) which continues to weep when the snow melts above it. Both Pausanias and Quintus Smyrnaeus refer to this

rock of Niobe as one which resembled a weeping woman when they saw it from a distance.

The story of Niobe well illustrates the favourite Greek theme that the gods are quick to take vengeance on human pride and arrogance (*hybris*). Niobe is the subject of lost tragedies by both Aeschylus and Sophocles, and Ovid tells her story in his *Metamorphoses*. The number of her children, which varies with different authors, is generally given after Homer as seven sons and seven daughters. In certain late accounts one son and one daughter were said to have survived. The name Niobe may be of non-Greek origin and derive from Asia Minor, which seems also to be the source of her story.

See Pauly-Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft*, vol. 17, col. 644–706 (1936).

NIOBIUM, a metallic element closely associated with tantalum in ores and in properties, was named in 1844 by German chemist Heinrich Rose after the goddess Niobe, daughter of Tantalus. Actually, it was first discovered in 1801 in a New England mineral by British chemist Charles Hatchett, who called the element columbium (*see* COLUMBITE). International agreement among chemists in 1949 established the name niobium with symbol Nb, but the name columbium, symbol Cb, persisted strongly in the U.S. metallurgical industry.

The pure metal looks like steel and has a combination of properties that make it a valuable engineering material. Alloying additions enhance its usefulness. Its melting point of 2,468° C. (4,474° F.), combined with a density of 8.57 (only slightly more than iron), excellent ductility and good strength, makes it attractive as an alloy base for high-temperature applications. Although it has excellent corrosion resistance, niobium needs protection against oxidation above about 400° C.; hence, alloying, a protective coating or operation in vacuum or inert atmosphere is needed for prolonged high-temperature use. Because of its relatively low resistance to thermal neutrons, compatibility with uranium, corrosion resistance and strength, some niobium alloys are used in atomic-energy reactors. An early application has been for cladding fuel elements in atomic-powered submarines. Niobium is a useful alloying addition to many other metals. As ferroniobium (ferrocolumbium) it is added to some stainless steels to give stability on welding or heating. Additions of only 0.05% niobium raise the yield strength and refine the grain size of some carbon steels. Many hundreds of miles of gas pipeline, for example, are made from steel containing niobium.

Principal sources of niobium are the minerals columbite and the low-grade but more abundant pyrochlores, a series of complex oxides containing essentially calcium, sodium, niobium, tantalum and fluorine, with Africa, Brazil, Canada and Norway among the chief suppliers. Natural abundance is estimated to be somewhat less than that of nickel. A chief difficulty in preparation of the pure metal has been separation from tantalum. This is done commercially by solvent extraction in a hydrofluoric-sulfuric acid, methyl isobutyl ketone system, although fractional distillation of chlorides resulting from chlorination of ferroniobium is an alternate method. Among methods for reducing the purified compounds to metal are reduction of the oxide by carbon or niobium carbide in vacuum, hydrogen or magnesium reduction of the chloride, sodium reduction of double fluorides and fusion electrolysis. Niobium is consolidated and purified further by electron-beam or vacuum-arc melting. Vacuum sintering of powder is also used for consolidation.

Compounds of niobium are of minor importance. However, the carbide, usually blended with tantalum or tungsten carbides, is used in the making of some cemented carbide items, or cermets, for high-temperature use. In the chemical industry the metal is useful because of corrosion resistance although it is inferior to heavier, more expensive tantalum in hydrochloric acid, hot concentrated sulfuric acid and concentrated alkalies. In electronics, the superconductivity of niobium-zirconium and niobium-tin, together with ease of fabrication, is of interest in making fine wire for magnetic coils.

Niobium has the atomic number 41; its atomic weight is 92.906. One stable form of the element, Nb^{93}, is known, and 12 radioactive isotopes (89, 90, 91, 92, 94, 95, 96, 97, 98, 99, 100 and 101) have been prepared. The electron arrangement in the outer unfilled orbits (N and O) is: $4s^2$, $4p^6$, $4d^4$, $5s^1$.

NIOBRARA, the largest river in northern Nebraska, U.S., rises near Lusk, Wyo., flows east across the High Plains, the northern fringe of the Nebraska sandhills and the low eastern plains to join the Missouri river at Niobrara. The name is of Indian origin and means "running water" or "spreading water." Both designations are apt: the Niobrara has a more uniform flow than do most plains streams, because of steady groundwater contributions from tributaries in the sandhills; in its lower course it is wide and shallow. It is 447 mi. long, drains 12,000 sq.mi. and has an annual flow of 1,100,000 ac.ft., with a peak in late spring and summer. In the late 1950s, about 24,000 ac. in the river basin were irrigated, mainly in the western reach where Box Butte reservoir served 12,000 ac. at Mirage flats. Ranching, concentrated in the sandhills, has traditionally been the most important activity in the Niobrara basin. Additional sources of farm income have been hogs, corn and wheat. *See* also NEBRASKA: *Physical Geography*; *The Economy*. (D. S. Sr.)

NIORT, a market town of western France, *préfecture* of the *département* of Deux-Sèvres, is situated 63 km. (39 mi.) E.N.E. of La Rochelle by road on the Sèvre river, above its silted estuary. Pop. (1962) 36,265. Below Niort the Sèvre, navigable for small craft, now traverses an amphibious tract of reclaimed marshland (Marais Poitevin), which occupies a former re-entrant of the sea. The town grew up on the left bank of the river in the shelter of Henry Plantagenet's castle, erected in 1155, the keep of which dominates the river by two square towers. Françoise d'Aubigné, marquise de Maintenon (1635–1719), second wife of Louis XIV was born in Niort. The town was one of the centres of Protestantism in western France and suffered severely by the revocation of the Edict of Nantes in 1685. It has old tanning and leather working industries, but is chiefly a market and rural service centre for the productive Marais Poitevin and other neighbouring farmlands of Poitou and the southern part of Vendée. South and north of the castle the tall spires of the church of Notre Dame (14th–1540) and the 19th-century church of St. André overlook the old town near the river. Back from the river the street system focuses upon the spacious Place de la Brèche. (AR. E. S.)

NIPPON, the Japanese pronunciation of the Chinese name of Japan, "sun origin." *See* JAPAN.

NIPPUR, an ancient sacred city of Mesopotamia, was situated on the Euphrates river about 45 mi. S.E. of Babylon; the site, the modern name of which is Niffer (Nuffar), lies about 100 mi. S.S.E. of Baghdad in the Diwaniyah *liwa* of Iraq. Although it was never a political capital, Nippur played a dominant role in the religious life of Mesopotamia. Long since, the river has moved miles westward and the ruins of the city resemble a series of low hills rising from the surrounding alluvial plain.

In Sumerian mythology Nippur apparently existed from the beginning of time. It was the home of Enlil, the storm god, the representation of force, the god who carried out the decrees of the assembly of gods that met at Nippur to determine the course of events and the destiny of all beings. It was at Nippur that Enlil, according to one account, created man. As the god of force and the executor of the divine assembly's will, Enlil could delegate his authority to the temporal ruler of any of the Sumerian city-states and, in later times, to the kings of Babylonia and Assyria. Although a king's armies could subjugate the country, the transference to that king of Enlil's divine power to rule had to be sought and sanctioned. The necessity of this confirmation from the divine assembly at Nippur made the city and Enlil's sanctuary there especially sacred, regardless of which dynasty ruled Mesopotamia. (*See* also BABYLONIA AND ASSYRIA: *Religion: Sumerian Pantheon: Farming Regions*.)

The first archaeological expedition from the United States to Mesopotamia excavated at Nippur from 1889 to 1900; the excava-

tions were resumed in 1948. The southwestern half of the city was a residential and business district; the records of the commercial house of the Murashu family (*c.* 445–*c.* 403 B.C.) were found there. The eastern section, also residential, has been called the scribal quarter because so many cuneiform tablets were found in the houses. Most of the tablets were business documents, but many copies of Sumerian hymns, myths and wisdom texts were also recovered. In fact, the excavations at Nippur have been the primary source of the literary writings of Sumer. The northern section of the city, the religious quarter, contained temples to Enlil and other gods and goddesses of the Sumerian pantheon.

Very little is known about the prehistoric town except that it did exist. It probably was centred beneath the religious quarter of the town. By the mid-3rd millennium B.C. the city probably had reached the extent of the present ruins and was fortified. The most important temple, dedicated to Enlil, undoubtedly underlies the existing ziggurat to the same god. Naramsin, king of Akkad from *c.* 2267 to 2230 B.C. (or 2291–55), rebuilt the city walls and temples, but most of his work was obliterated by the extensive and monumental constructions of Ur-Nammu, the first king of the 3rd dynasty of Ur, who reigned from *c.* 2130 to *c.* 2112 B.C. (or 2113–2096). Ur-Nammu laid out Enlil's sanctuary, the Ekur, in its present form. The sacred enclosure was oriented with its corners to the cardinal points of the compass. A ziggurat or temple tower, probably three stories high, and a temple were built in an open courtyard surrounded by casemated walls which contained shrines, priests' quarters and storerooms. The following kings of Ur, Isin and Larsa kept the sacred buildings in repair but there is little evidence of temple construction by the kings of Babylon (*c.* 1800–1600 B.C.), although Nippur was a thriving city at that time. Later, the Kassite and Assyrian kings made extensive repairs and restorations. Minor changes in Neo-Babylonian times brought the glories of Nippur to an end. The Parthians constructed a massive citadel that completely buried Enlil's sanctuary and its enclosure walls. From the close of the Parthian period in the 3rd century A.D. the city fell into decay and probably was no more than a village until it was abandoned in the 12th or 13th century A.D.

NIRVANA, a Sanskrit term (Pali NIBBANA), names the ultimate goal of Buddhist thought, aspiration and practice. Literally, it means "waning away" (as of a flame when the fuel is exhausted). What is here implied is the waning away of deluded egocentricity, with its attendant passionate, sensual and selfish desires. According to the Buddha's analysis of the human situation, these deluded desires fetter man, together with all sentient beings, to the round of rebirth and consequent ill or suffering (*dukkha*), one afflicted existence succeeding another. When these desires are transcended by those who follow the Path which he announced, there is the experience of spiritual freedom and enlightenment that is Nirvana. The corresponding term, Nibbana, in the Pali Buddhist scriptures, is held by some expositors to refer explicitly to the negation (*ni*) of the "jungle of lust, ill-will and delusion" (*vana*). In a sense, therefore, Nirvana means extinction. But most Buddhists emphasize that this does not mean annihilation; Nirvana is not the end of life, but rather the end of all that confuses life and hinders well-being; it is "the extinction of afflictions."

As such, it is poetically described in the Buddhist scriptures as the harbour of refuge, the further shore, the cool cave, the matchless island amid the floods, the home of ease, the holy city. It is also said to be changeless, deathless and without limitation. It is the "not born, the not-become"; it is "neither origination nor annihilation." The reality beyond all change and suffering, it is peace, security, supreme joy, unspeakable bliss.

While interpretations vary in different contexts of Buddhist thought, there is general agreement that Nirvana is an exalted spiritual state that may be realized here and now. In the Theravada (Hinayana) tradition, the nature of the goal is indicated to some extent by the degrees of moral and spiritual mastery set forth in the Noble Eightfold Path and by what is said of the character and condition of the saint (the *arahat*) who has followed this Path: Nibbana is "the state of him who is worthy." In the Mahayana tradition, to realize Nirvana is to realize one's own inherent Buddha-nature, and this is generally interpreted as a change of outlook rather than a change of being. In Vedanta (Indian) thought Nirvana is identified with union with Brahman. *Parinirvana*, used sometimes with particular reference to the state after death, signifies complete achievement but in itself implies neither immortality nor annihilation—one of the questions to which the Buddha is said to have given "indeterminate" answers. For Nirvana is "deep, unfathomable." As it means enlightenment there is, apart from this enlightenment, no knowing until the goal itself is reached. Nirvana has to be experienced. All that can be defined is the Path. *See* also METEMPSYCHOSIS: *Eastern Thought*.

NIS (NISH), chief town of the Nis *srez* (district) in the Socialist Republic of Serbia, Yugos., stands on the Nisava river not far from its confluence with the southern Morava, 246 km. (153 mi.) S.S.E. of Belgrade by road via Kragujevac. Pop. (1961) 84,741. The town is important both commercially and also strategically since it commands the only two valleys affording easy access from central Europe to the Aegean; it is the meeting point of several Balkan highways; and the main railway from Belgrade and the north divides there for Sofia, Bulg., and Salonika, Greece. It has railway workshops and light industries. Good coal supplies are within easy reach. A university was founded in 1960.

The ancient Roman city Naissus, which probably superseded a Celtic settlement, was mentioned as an important place in the second century in Ptolemy's *Guide to Geography*, and the old fortress on the right bank of the river is believed to have been built on its site. Under its walls in A.D. 269 the emperor Claudius destroyed the army of the Goths, and Constantine the Great was born there (*c.* 280). The emperor Julian improved its defenses but the town was destroyed by the Huns under Attila in the 5th century, and restored by Justinian. In the 9th century the Bulgarians conquered it, but ceded it in the 11th century to the Hungarians, from whom the Byzantine emperor Manuel I took it in 1173. Toward the end of the 12th century the town was in the hands of the Serbian prince Stephen Nemanya (Stevan Nemanja), who there received hospitably the German emperor Frederick I Barbarossa and his crusaders. In 1375 the Turks captured Nis from the Serbians. In 1443 the Hungarians and the Serbs retook it from the Turks, but in 1456 it again came under Turkish rule and remained for more than 300 years the most important Turkish station on the road between Hungary and Constantinople. In the first Serbian uprising, 1809, the Serbians, led by Stephan Sindjelic, resisting the Turkish onslaught near Nis, fired their powder magazine and destroyed both themselves and the enemy. The Turks built a brick tower about 1¼ mi. S.E., in which they embedded more than 900 Serbian skulls. The ruins are still called Cele Kula ("Tower of Skulls"). The Serbian army liberated Nis in 1877 and the town was ceded to them by the treaty of Berlin (1878). In World War I, Nis was for a period the capital of Serbia, and on Nov. 24, 1914, the Serbian parliament and government issued their declaration of war aims: liberation and unification of all Serbs, Croats and Slovenes. In World War II Nis was severely damaged by bombing and many streets in the old Turko-Byzantine style were destroyed. (V. DE.)

NISHAPUR (NEYSHABUR), a town in Khurasan *ostan* (province) of Iran, lies 46 mi. W. of Meshed (Mashad), and 3,920 ft. above sea level. The town, which has shifted its position repeatedly in historic times, is situated in a wide, well-watered and

fertile plain at the southern foot of Kuh-e Binalud. Pop. (1964 est.) 33,397. The surrounding area produces grain and cotton. Besides the marketing and other activities of a local centre there is some manufacturing and processing including leather, carpets, vegetable oil, cotton ginning and pottery. At Ma'dan, 32 mi. N.W. of Nishapur at 5,100 ft., are the famous turquoise mines which have supplied the world for at least 2,000 years. Nishapur is linked by road, and since 1958 by railway, with Teheran and Meshed.

Nishapur derived its name from its alleged founder Shapur (A.D. 241–272). It was once one of the four great cities of Khurasan, rivaling Ray (Rhages), and was an important place in the 5th century as the residence of Yazdegerd II (438–457). But when the Arabs came to Khurasan (641–642) it was of such minor importance that it did not even have a garrison. Under the Tahirids it became a flourishing city again and rose to importance under the Samanids (874–999). Tughril (Toghrul), the first Seljuk ruler, made Nishapur his residence in 1037. The decline set in in 1153 when the Ghuzz Turkmens partly destroyed the town. In 1208 most of it was devastated by earthquake and was hardly rebuilt when it was ravaged by the Mongols. Rebuilt, it suffered again from Mongol invasion (1269) and from another earthquake, and never again achieved its former greatness.

The Gadam Gar (1643), a fine domed mausoleum, lies a few miles to the east. Excavations by the Metropolitan Museum of Art, New York, in 1934–40, disclosed rich, significant architectural and artistic remains of both the Seljuk and pre-Seljuk periods. Adjacent to the mosque of the Imamzadeh Mahruk, 4 mi. S.E. of Nishapur, is the tomb of the astronomer-poet Omar Khayyam, who was born in Nishapur—a fine marble shaft and sarcophagus built in 1934. Nearby is the grave of the celebrated poet and mystic Farid ud-din 'Attar. (H. Bo.)

NISHIDA KITARŌ (1870–1945), leading Japanese philosopher in the first half of the 20th century, was born April 19, 1870, in a village near Kanazawa. He taught philosophy in Kanazawa and Tokyo and then was appointed professor of philosophy at Kyōto University (1913–28).

From his Kanazawa days, and for some time after he moved to Kyōto, Nishida was deeply engaged in Zen meditation. In his *Study of Good* (1911), he advocated the idea of "pure experience," which knows events as they are without the addition of thought or reflection. In *Intuition and Reflexion in Self-consciousness* (1917), he investigated more logically and thoroughly, under the influence of H. Bergson and Neo-Kantianism, the relation between thought and pure experience. This led to the idea of a self-developing system of self-consciousness, as in Fichte's philosophy. His mystical nature, however, induced him to break the shell of transcendental idealism in order to gain a new understanding of ultimate reality.

After his *From the Acting Self to the Seeing Self* (1927), Nishida named his mystical conception of reality, in accordance with Buddhist tradition, "Nothingness" (*mu*). As this means the ultimate identity of subject and object, he sought to derive the individual reality of everything in the world—things as well as selves—from this ultimate, all-enveloping Nothingness. In his last stage (cf. *Philosophical Essays*, 7 vol. 1935–46) he further developed this idea into a philosophy of history. He died July 7, 1945, at Kamakura.

The following works of Nishida are available in English translation: *A Study of Good*, translated by V. H. Viglielmo (1960); *Intelligibility and the Philosophy of Nothingness*, translated by R. Schinzinger (1958); and excerpts from *The Problem of Japanese Culture*, translated by M. Abe, in *Sources of Japanese Tradition*, pp. 857–872 (1958), in the "Introduction to Oriental Civilizations" series.

See further JAPANESE PHILOSOPHY: *Modern Japanese Philosophy*. (T. Y.)

NISHINOMIYA, Japanese city of Hyōgo prefecture, located midway between Kōbe and Ōsaka in the continuous urban-industrial belt along the eastern Inland seacoast of Honshū. Pop. (1960) 262,608. It occupies a narrow lowland between Ōsaka bay and interior Mt. Rokkō. Nishinomiya is famed for its fine sake (rice wine) and produces 30 different brands. Its coastal sections are assigned to industry (metals, machinery, chemicals, rubber goods, soap, cosmetics and beer) and to bathing resorts. It has a large professional baseball stadium and excellent railway and road connections with adjacent eastern and western urban areas. (J. D. Ee.)

NISUS, the name of two figures in classical mythology and literature.

1. Nisus, in Greek mythology, was a son of Pandion, king of Megara, and is eponymously connected with the Megarian port of Nisaea. Nisus had a purple lock of hair with magic power: if preserved, it would guarantee him life and continued possession of his kingdom. When Minos (*q.v.*) besieged Megara, Nisus' daughter Scylla fell in love with Minos or was bribed; she betrayed her city by cutting off her father's purple lock. Nisus was killed or killed himself and became transformed into a sea eagle. Minos despised Scylla and brought about her death either by dragging her, tied, after his ship or by abandoning her, so that she desperately swam after him and drowned. Scylla then changed into a sea bird (Gr. *keiris*, Lat. *ciris*), possibly a heron, constantly pursued by the sea eagle. The story appears as early as Aeschylus, but the most famous accounts occur in the *Ciris*, often attributed to Virgil, and in Ovid's *Metamorphoses*, 8, 1 ff.

2. Nisus in Virgil's *Aeneid* is a Trojan, son of Hyrtacus close friend of Euryalus. In the funeral games, when he slips and falls, he helps Euryalus win the foot race by tripping the leader (*Aeneid* 5, 315 ff.). Later, fighting the Italians, he sacrifices himself vainly to rescue Euryalus from the enemy, but earns poetic immortality (*Aeneid* 9, 176 ff.). (WM. S. A.)

NITERÓI, a city and port of Brazil, and capital of the state of Rio de Janeiro, is located on the eastern side of the entrance to Guanabara bay opposite the city of Rio de Janeiro, with which it is connected by ferry. Pop. (1960) 228,826. Like Rio de Janeiro, this city is located on low ground at the heads of the numerous bays that indent the shore. The several sections of the city are separated by steep rocky ridges that extend into the water. Niterói is separated from the open ocean by the steep slopes of the main ridge running parallel to the coast.

In addition to serving as capital of Rio de Janeiro state since 1835 (except for the period 1894–1903 when Petrópolis was the capital), Niterói is also a residential suburb of Rio de Janeiro city. The best residential districts include Icaraí and São Francisco, both of which are bordered by fine beaches. In and around Niterói there are important manufacturing industries, including Brazil's chief shipbuilding and repairing yards and metal industries which use steel manufactured at Volta Redonda (*q.v.*). There are textile mills and food processing plants; other manufactures include flat glass, matches, tobacco products, furniture, chemicals, explosives and pharmaceuticals. There is a large cement plant nearby. The central business district is in the part of the city known as São Lourenço.

The first settlement on the eastern side of the bay was made by the Portuguese in 1671. At this time a chapel was built in Praia Grande near an Indian village, not far from one of the present ferry terminals. The settlement became a village in 1819 when it was named Villa Real da Praia Grande. In 1834 the city of Rio de Janeiro and the federal district were separated from Rio de Janeiro state; the following year Praia Grande became the capital of the state. In 1836 it became a city and was renamed Niterói, a name derived from the Indian word *Nyterõi*, "hidden water." In spite of the new residential suburbs and industrial districts, Niterói remains even more characteristically Portuguese than its neighbour across the mouth of the bay; the narrow irregular streets and the architecture of the buildings are little changed. The name of the city was formerly spelled Nictheroy. (P. E. J.)

NITHARD (d. 844), Frankish count whose historical work gives an invaluable narrative of the dissension between the sons of the emperor Louis I the Pious, was the son of Charlemagne's daughter Bertha by Angilbert, head of Charlemagne's chancery and poet (called the "Homer" of the court). Through his mother, therefore, Nithard was the cousin of Louis I's sons, and when war broke out between them on their father's death, he emerged as the valued counselor of the youngest of them, Charles II the Bald

A formidable military strategist, he played an important part in the battle of Fontenoy (June 25, 841), when Charles defeated his eldest half brother Lothair I. In the same year Charles asked Nithard to write an account of contemporary events. Heavily biased against Lothair, Nithard's history (*Historiarum libri iv*) is nevertheless a work of considerable interest, almost the sole source on the war. He had important sources and official documents at his disposal, providing, for example, the full text of the Strasbourg oaths of Feb. 842, sworn by Charles in German and by his half brother Louis the German in French. Nithard rarely had leisure to write until some time after the events that he describes; even so, his account of the battle of Fontenoy, written four months after it took place, is remarkably vivid.

In 843 Nithard was made lay abbot of St. Riquier (east of Abbeville) by Charles the Bald, but held this benefice for a few months only: he was killed on June 14, 844, in a fierce battle against the forces of Pepin II of Aquitaine, who was trying to prevent reinforcements from reaching Charles at the siege of Toulouse. The text of his work is printed in *Monumenta Germaniae historica*, series *Scriptores*, 3rd ed. (1907), and, with French translation, by P. Lauer, *Histoire des fils de Louis le pieux* (1926). (J. De.)

NITHSDALE, WILLIAM MAXWELL, 5TH EARL OF (1676–1744), Scottish Jacobite chiefly remembered for being rescued by his wife from the Tower of London, was the only son of Robert (d. 1683), 4th earl, to whom he was served heir in 1696 (*see* also MAXWELL). He married Winifred, daughter of William Herbert, 1st marquess of Powis. Nithsdale soon became known as a Jacobite and in 1712, anticipating the possible consequences of his support for the Stuarts, he resigned his estate to his son William. He took part in the Jacobite rising of 1715, was captured at Preston and was tried and condemned to death in Jan.–Feb. 1716. The countess, on hearing of her husband's capture, went to London, traveling in very difficult conditions, and there gained access to the king. George I, however, refused to receive her petition, and when she knelt before him and took hold of the skirts of his coat he dragged her half across the room before he could break away. Finding that no pardon could be obtained, the countess laid a plan to rescue her husband from the Tower of London. With the help of two Jacobite ladies, she cleverly helped her husband escape from his cell on the night before the day fixed for the execution (Feb. 24) by disguising him as a woman.

The earl escaped from England and was followed by his wife after she had gone back to Scotland to rescue important legal papers. After a short stay in France, the earl and countess went to Rome, where they lived in poverty and obscurity. The earl died there on March 20, 1744, and the countess in 1749.

NITON: *see* RADON.

NITRA (Ger. NEUTRA; Hung. NYITRA), a town in the West Slovak *kraj* (region) of southern Slovakia, Czech., lies at the foot of the small Zobor massif above the east bank of the Nitra river and 116 km. (72 mi.) E.N.E. of Bratislava. Pop. (1961) 36,479. It was important from the 9th century onward as a strongpoint and a religious centre. The first Christian church of Slovakia was established there (830) and was consecrated by the missionary saints Cyril and Methodius. The ramparts of the medieval castle still surround the upper town, now crowned by the 18th-century bishop's palace. The railway constructed during the 19th century up the west (opposite) bank of the river bypassed the town but this has been compensated in part by a road bridge and a good road network. To the south is a rich region of Slovak arable farming on chernozem soils and the town has food-processing industries and an agricultural college. Nearby at My.narce is a factory for industrial ceramics. (H. G. S.)

NITRE, naturally occurring potassium nitrate, or saltpetre; "cubic nitre," or Chile saltpetre, is sodium nitrate. A source of nitrogen compounds, nitre was employed in the earliest recorded preparation of nitric acid (*see* NITRIC ACID AND NITRATES) and was used in the manufacture of gunpowder, fireworks, etc. It occurs as crusts on the surface of the earth, on walls, rocks, etc., and in caves. It forms in certain soils in Spain, Italy, Egypt, Iran and India. It occurs with sodium nitrate in Chile, and in the United States it has been found in caves in the Mississippi valley. The colour is white and it has a vitreous lustre. The composition is KNO_3, with 46.5% K_2O (potash) and 53.5% N_2O_5. *See* also POTASSIUM: *Potassium Nitrate*.

NITRIC ACID AND NITRATES. Nitric acid, HNO_3, an important mineral acid, was one of the earliest of the nitrogen compounds to be prepared and used. Its preparation by the distillation of a mixture of nitre (potassium nitrate), alum and blue vitriol is ascribed to Geber (*q.v.*). A similar method was described by Albertus Magnus in the 13th century and by Raimon Lull, who prepared the acid by heating nitre and clay and called it *eau forte*.

In 1648 J. R. Glauber devised the process in common use for many years, viz., by heating a nitrate with concentrated sulfuric acid. The true nature of nitric acid was not determined until the 18th century when A. L. Lavoisier (1776) showed that it contains oxygen. In 1784 H. Cavendish synthesized it by passing a stream of sparks through humid air, proving that nitrogen is also a constituent of the atmosphere. J. L. Gay-Lussac and C. L. Berthollet established its exact composition in 1816. Nitric acid has been known as *aqua dissolutiva, aqua prima, spiritus acidus nitri, spiritus nitri fumans Glauberi* and aqua fortis.

Free nitric acid, formed in moist air by the discharge of atmospheric electricity (lightning), is found to a very slight extent in rain water and is also formed in the soil by the oxidation of nitrogenous organic matter. It is neutralized by the basic substances in the soil to form nitrates, principally saltpetre, KNO_3, and Chile saltpetre, $NaNO_3$, the latter being found in greater abundance and concentrations.

Physical Properties.—Pure 100% nitric acid is a colourless liquid whose specific gravity at 25° C. relative to water at 4° C. is 1.50269, melting point −41.59° C., and boiling point 86° C. at one atmosphere of pressure. It fumes strongly on contact with moist air and is miscible with water in all proportions.

A water solution containing 68% of the acid, which is the approximate composition of the concentrated acid of commerce, is a constant-boiling or azeotropic mixture at atmospheric pressure with a boiling point of 120.5° C. and a specific gravity of 1.41. A solution containing less than 68% nitric acid may be separated by distillation at atmospheric pressure into the constant-boiling mixture and a distillate of more dilute acid; one with more than 68% nitric acid yields a residue of the constant-boiling mixture and a distillate of the more concentrated acid.

The very concentrated or pure acid undergoes decomposition when boiled and, with the water formed, may be converted to the constant-boiling mixture by repeated distillation. The composition of the constant-boiling mixture varies with the pressure at which it is distilled.

Chemical Properties.—Pure nitric acid or its concentrated solutions decompose slowly into water, nitrogen dioxide and oxygen: $4HNO_3 \rightarrow 2H_2O + 4NO_2 + O_2$; the rate of the decomposition is increased by light and by higher temperature. The concentrated acid is therefore usually coloured yellow because of the presence of the nitrogen dioxide, some of which remains in the solution. Nitric acid forms two compounds with water in the solid phase, the monohydrate, $HNO_3 \cdot H_2O$, melting point −37.68° C., and the trihydrate, $HNO_3 \cdot 3H_2O$, melting point −18.47° C.

Nitric acid may be considered to be the hydrate of nitrogen pentoxide although it is almost never prepared by hydration of the oxide. Conversely the pentoxide is normally prepared by dehydrating the concentrated acid with phosphorous pentoxide: $2HNO_3 + P_2O_5 \rightarrow N_2O_5 + 2HPO_3$. Nitrogen pentoxide is a white solid that sublimes at 32.4° C. and decomposes readily into nitrogen dioxide and oxygen.

Nitric acid is a strong acid; in dilute water solutions it is almost completely ionized to hydrogen ions, H^+, and nitrate ions, NO_3^-. Its salts with strong bases are not hydrolyzed in aqueous solution and are neutral to indicators. It neutralizes hydroxide bases and salts of weak acids to form nitrates (*see* below). Because of its strong oxidizing properties, a dilute solution of the acid does not yield hydrogen when treated with metals but is reduced to one of the oxides of nitrogen, to nitrogen or to ammonium ion. How-

ever, with very active metals (magnesium, for example), some hydrogen is liberated along with the other reduction products.

Most of the nitric acid produced is consumed in the manufacture of fertilizers, explosives, plastics, lacquers, synthetic fabrics and dyes by the reaction of the acid on organic compounds. Fuming nitric acid is used as an oxidizer in rocket propellants.

In one type of reaction, organic nitrates and water are formed when alcohols and other compounds containing OH groups react with the acid. Nitroglycerol, commonly called nitroglycerin, is made by the treatment of glycerol with a mixture of concentrated nitric and sulfuric acids: $C_3H_5(OH)_3 + 3HNO_3 \rightarrow C_3H_5(NO_3)_3 + 3H_2O$. The sulfuric acid combines with the water, increasing the concentration of nitronium ion (NO_2^+), a powerful nitrating agent. Cellulose in the form of cotton or wood fibres is similarly treated to obtain cellulose nitrates. The extent of nitration (*i.e.*, the number of nitrate radicals combining with a unit of the cellulose) is controlled to produce either guncotton (smokeless powder) or, with less nitration, the base for pyroxylin lacquers and plastics and certain types of fibres. In organic nitrates the nitrogen atom is bonded to an oxygen atom, which in turn is linked to a carbon. Another type of reaction of nitric acid and organic compounds involves the formation of nitro compounds in which the nitrogen atom of the group $-NO_2$ is bonded directly to the carbon atom.

Toluene (methylbenzene) reacts with nitric acid in the presence of concentrated sulfuric acid to form trinitrotoluene, more commonly known as TNT: $C_6H_5CH_3 + 3HNO_3 \rightarrow CH_3C_6H_2(NO_2)_3 + 3H_2O$. (*See* EXPLOSIVES.)

Nitric acid is a powerful oxidizing agent; it oxidizes nearly all of the metals except platinum, rhodium, iridium, tantalum and gold. Most metals yield nitrates, but with tin, arsenic, antimony, tungsten and molybdenum the oxides of the metals are formed. The behaviour of the acid as an oxidizing agent is complex because of the number of possible reduction products that may be obtained. The oxidation or valence number of the nitrogen in nitric acid is $^+5$; it may be reduced to nitrogen dioxide, NO_2 ($^+4$), nitric oxide, NO ($^+2$), nitrogen, N_2 (0), or to ammonium ion, NH_4^+ ($^-3$), depending upon the temperature, the concentration of the acid, the presence of catalysts and the activity of the metal or other reducing agent involved.

In general, the more concentrated the acid the less the change in the oxidation number of the nitrogen. For example, copper reduces the concentrated acid to NO_2: $Cu + 4HNO_3$ (concentrated) $\rightarrow Cu(NO_3)_2 + 2NO_2 + 2H_2O$, and the dilute acid to NO: $3Cu + 8HNO_3$ (dilute) $\rightarrow 3Cu(NO_3)_2 + 2NO + 4H_2O$. A stronger reducing agent may cause a greater change in the oxidation number of the nitrogen, as:

$$4Zn + 10HNO_3 \text{ (dilute)} \rightarrow 4Zn(NO_3)_2 + NH_4NO_3 + 3H_2O$$

wherein the reduction product is ammonium nitrate.

On the other hand, the concentrated acid may oxidize the metal or nonmetal to a higher valence stage than does the dilute acid, as:

$$S + 6HNO_3 \text{ (concentrated)} \rightarrow H_2SO_4 + 6NO_2 + 2H_2O, \text{ and}$$
$$3S + 4HNO_3 \text{ (warm, dilute)} \rightarrow 3SO_2 + 4NO + 2H_2O$$

When iron, copper or chromium is placed in contact with concentrated nitric acid it becomes inactive or passive to the acid and to certain other substances with which it normally reacts; passive iron reduces neither hydrogen ion nor cupric ion, and passive copper does not reduce silver ion. Passivity may be destroyed by scratching the surface, by the action of reducing agents, or by the effect of a strong magnetic field. It was thought at mid-20th century that the formation of an oxide film on the surface of the metal was the cause of the phenomenon.

Nitric acid is highly toxic if taken internally, producing a widespread gastroenteritis, burning pain in the esophagus and abdomen, and bloody diarrhea. Death may occur from collapse or from secondary destructive changes in the intestinal canal. On the skin a characteristic yellow staining appears, due to the formation of xanthoproteic acid. Copious quantities of water and mild bases such as sodium bicarbonate solution will assist in neutralizing the effects of internal and external exposures.

Manufacture.—In the laboratory pure anhydrous nitric acid is prepared by gently heating an equimolal mixture of pure concentrated sulfuric acid and pure sodium nitrate under vacuum and condensing the evolved gaseous acid at a temperature near or below its melting point. The reaction is $H_2SO_4 + NaNO_3 \rightarrow NaHSO_4 + HNO_3$ (gas).

Commercially, nitric acid is manufactured by three processes. The older method, practically obsolete at mid-20th century is similar to the laboratory method. Chile saltpetre, a commercial form of sodium nitrate, is heated with an equimolal amount of concentrated sulfuric acid under reduced pressure in iron retorts. Nitric acid boils out of the reaction mixture and is condensed in glass containers. An attempt to bring about a reaction between another molecule of sodium nitrate with the second hydrogen in the sulfuric acid molecule results in decomposition of the nitric acid because of the high temperatures necessary to make the reaction go.

The second and most common method of manufacturing nitric acid is by catalytic oxidation of ammonia. Ammonia can be synthesized as cheaply per pound of nitrogen as Chile saltpetre can be mined and purified, and as a result it largely supplanted the latter as a source material. A mixture of 10% ammonia and 90% air is heated to 300° C. and passed over a platinum gauze catalyst, which is heated initially to 900°–1,000° C. Heat liberated in the reaction is sufficient to maintain the catalyst temperature. About 90% of the ammonia is oxidized to nitric oxide: $4NH_3 + 5O_2 \rightarrow 4NO + 6H_2O$. From the catalyst the gases pass into absorption towers where two reactions take place: $2NO + O_2 \rightarrow 2NO_2$ and $3NO_2 + H_2O \rightarrow 2HNO_3 + NO$.

The third method of nitric acid manufacture involves the direct union of atmospheric oxygen and nitrogen in an electric arc: $N_2 + O_2 \rightarrow 2NO$, followed by the last two reactions of the ammonia process. Equilibrium in the arc reaction favours formation of nitric oxide only at very high temperatures. For example at 3,900° C. the reaction is only 10% complete at equilibrium. However, if the reaction mixture is quenched quickly to a temperature below 1,000° C. it may be frozen at the high-temperature equilibrium proportions. Under the most favourable conditions, the yield of nitric oxide is only about 2.5%. The process is not commercially competitive with the ammonia oxidation process even in locations where electric power is cheap. (*See* NITROGEN, FIXATION OF.)

Nitrates.—Inorganic nitrates are chemical compounds with the type formula $Me(NO_3)_n$, where Me represents a metal atom and n may be one, two, or more depending on the valence of the metal. Nitrates are crystalline solids at ordinary temperatures. They may be white or coloured, depending on the metallic constituent. As a group they are the most water soluble of all metallic salts. Nitrates are prepared by reaction of the desired metal, its oxide or its carbonate with nitric acid.

Nitrates of base metals decompose according to the equation $2NaNO_3 \rightarrow 2NaNO_2 + O_2$ when heated, whereas nitrates of the less active metals are converted to oxides under the influence of heat: $2Zn(NO_3)_2 \rightarrow 2ZnO + 4NO_2 + O_2$. Anhydrous cupric nitrate, ferric nitrate and mercuric nitrate may be sublimed under careful heating, but uranyl nitrate, nickel nitrate, cobalt nitrate, cadmium nitrate and manganous nitrate decompose like zinc nitrate upon heating to form their oxides, nitrogen dioxide and oxygen. When heated to high temperatures, nitrates are strong oxidizing agents comparable to nitric acid.

Many nitrates are hygroscopic; *i.e.*, they absorb atmospheric moisture if left unprotected. Potassium nitrate is an important exception. Some nitrates contain water of crystallization when precipitated from aqueous solution, one or more water molecules per nitrate molecule forming an integral part of the crystalline structure of the solid material. The amount of water varies with the substance and the temperature. Heating the hydrated salts causes partial to complete conversion to oxide, depending on the metallic constituent. Nitric acid is driven off as a gas.

The nitrate ion has the structure of an equilateral triangle, with oxygen atoms surrounding the central nitrogen atom. Nitrates are determined qualitatively by reduction with ferrous ion, Fe^{2+}, to nitric oxide and subsequent formation of $FeNO^{2+}$, a complex

ion with a characteristic deep-brown colour. The reaction takes place in the presence of concentrated sulfuric acid, which is added to a solution of the unknown and ferrous sulfate in such a way that the two solutions do not mix. A brown layer at the interface indicates the presence of nitrate ion. Quantitative determination of nitrate ion is usually accomplished by reduction to ammonia by aluminum in alkaline solution, distillation of the ammonia into excess standardized sulfuric acid and back titration with standardized sodium hydroxide solution. Nitrate ion forms an insoluble salt with nitron (4,5-dihydro-1,4-diphenylimino-1,2,4-triazole), permitting the gravimetric determination of nitrates. For other nitrogen compounds *see* NITROGEN. *See* also references under "Nitric Acid and Nitrates" in the Index.

NITRIDES are binary compounds of nitrogen with the elements. They apparently do not occur in nature, although F. A. Bannister reported the presence of titanium nitride, TiN, in the mineral osbornite, found in the Busti, India, meteor. The simple nitrides may be regarded as derivatives of ammonia in which the hydrogen atoms are replaced by a metallic or nonmetallic element. Their composition may be represented by formulas corresponding to the normal valence (oxidation number) of the elements based upon their position in the periodic classification; for example, Group I, Li_3N; Group II, Mg_3N_2; Group III, AlN; Group IV, Si_3N_4. Where an element is capable of existing in several oxidation states, corresponding nitrides may be capable of existence; for example, PN and P_3N_5.

In addition to these simple nitrides, compounds with nitrogen are formed by such transition elements as chromium, iron and cobalt, whose structure and composition are more complex and do not conform to valence rules.

Reference is also made to three classes of binary nitrogen compounds that differ markedly from the simple nitrides: (1) the hydronitrogens, compounds of hydrogen and nitrogen, which formally resemble the hydrocarbons (*see* AMMONIA); (2) compounds with the more electronegative elements such as oxygen, sulfur and the halogens, which are discussed under the respective elements, and (3) the trinitrides, containing the N_3 radical, which are derivatives of hydrazoic acid, one of the hydronitrogens (*see* HYDRAZOIC ACID).

Preparation.—Many of the nitrides can be prepared by direct combination of the elements with nitrogen, but such reactions take place much less readily, and then usually only at higher temperatures, than the corresponding oxidation reactions. A few elements, notably lithium, magnesium and the alkaline earth metals, burn in air to give mixtures of the oxides and nitrides. Nitride formation is aided by using active nitrogen, by reducing the elements to a fine state of subdivision, by employing the amalgams and by using catalysts, such as lithium nitride. Nitride formation by direct combination has been observed to take place with the following elements: Mg, Ca, Sr, Ba, Li, Be, B, Al, La, Ce, Pr, Nd, Ti, Zr, Th, V, Cb, Ta, Cr, Mo, W, U, Mn, Fe, Co, Ni, Si, Ge and P. Despite their high reactivity, sodium, potassium, rubidium and cesium do not appear to form nitrides by direct combination. In general, elements of the B subgroups of the periodic classification show little inclination to react directly with nitrogen.

Nitrides may also be prepared by indirect methods, of which the following are the more important:

1. Mixtures of the oxides with carbon can be converted to nitrides by heating in a nitrogen atmosphere. This procedure is used for the preparation of aluminum nitride in accordance with the equation $Al_2O_3 + 3C + N_2 \rightarrow 2AlN + 3CO$ and constitutes the basis for the Serpek process for the fixation of atmospheric nitrogen (*see* NITROGEN, FIXATION OF). In some cases carbides can be heated directly with nitrogen as in the production of beryllium nitride: $3Be_2C + 2N_2 \rightarrow 2Be_3N_2 + 3C$.

2. Gaseous ammonia may serve as the nitriding agent for conversion of certain metals, oxides, sulfides and, in some instances, halides into nitrides. Cuprous oxide reacts with ammonia at 300° C. to yield some cuprous nitride, Cu_3N; at 600° C. zinc is converted into zinc nitride, Zn_3N_2.

3. Amides and imides of many elements undergo thermal decomposition to yield the nitrides. Nonmetallic halides, in particular, react with gaseous or liquid ammonia at ordinary temperatures to give the amides or imides, which may be heated to effect deammonation (removal of ammonia, analogous to dehydration by which hydroxides are converted to oxides) and eventually to give the nitrides. Thus, treatment of boron trichloride with ammonia gives first the diboron tri-imide, $B_2(NH)_3$, which on heating loses ammonia to form the nitride, BN.

$$BCl_3 \xrightarrow{NH_3} B_2(NH)_3 \xrightarrow[125^\circ\ C.]{above} BN$$

The amides of such metallic elements as magnesium, calcium, strontium, barium, zinc, cadmium, nickel and cobalt precipitate when potassium amide is added to solutions of their salts in liquid ammonia. These products likewise undergo deammonation at higher temperatures.

$$M^{2+} \xrightarrow{KNH_2} M(NH_2)_2 \xrightarrow{heat} M_3N_2$$
$$\text{(where } M = Mg, Ca, Sr, Ba, Zn, Cd, Ni, Co)$$

The amides of the alkali metals, with the exception of lithium, do not give nitrides on heating.

4. Reaction of certain metallic salts with potassium amide in liquid ammonia as the solvent medium affords a procedure whereby may be obtained nitrides that are unstable at the temperatures required to effect direct combination of metal with nitrogen. The following nitrides are precipitated from liquid ammonia solution under these conditions: mercuric nitride, Hg_3N_2, thallous nitride, Tl_3N, and bismuth nitride, BiN.

$$\left.\begin{matrix} Hg^{2+} \\ Tl^{+} \\ Bi^{3+} \end{matrix}\right\} \text{ in liquid } NH_3 + NH_2^- \text{ (from } KNH_2) \rightarrow \begin{matrix} Hg_3N_2 \\ Tl_3N \\ BiN \end{matrix}$$

(*See* also AMMONIA; SOLUTIONS.)

5. Aqueous ammonia converts the oxides of silver, gold and the platinum metals into highly explosive compounds that are assumed to be nitrogen compounds, possibly nitrides. These are often referred to as the fulminating metals.

6. Careful heating of the alkali and alkaline-earth azides (*see* HYDRAZOIC ACID) gives nitrides of the respective metals. A large number of nitrides have thus far been described in the chemical literature. These may be listed conveniently on the basis of type formula with M representing the element with which nitrogen is combined.

Nitrides of the Elements

Type formula	Where M represents
MN	B, Al, Sc, Y, La, Ce, Pr, Nd, Sm, Er, Ga, In, Si Te, Zr, P, As, Sb, Bi, V, Ta, Cb, Cr
MN_2	V, W
M_2N	Cb, Cr, W, Fe
M_3N	Li, Na, K, Rb, Cs, Cu, Tl
M_3N_2	Be, Mg, Ca, Ba, Sr, Ra, Zn, Cd, Hg, Ge, Zr, Cr, Mo, Mn, Co, Ni
M_3N_4	C, Si, Ti, Zr, Th, Ge, U
M_3N_5	P, Cb, Ta

A number of other nitrides have been described, but the identity of some of these is questionable: Si_2N_3, U_5N_4, U_5N_2, W_2N_3, Mn_5N_2, Mn_7N_2, Fe_8N and Fe_4N.

Properties and Uses.—Nitrides, like oxides, vary considerably in their stability and reactivity.

The nitrides of the noble metals (for example, Hg_3N_2 and BiN) decompose explosively into the elements on heating, whereas the nitrogen compounds of boron, silicon, titanium, zirconium, vanadium, tantalum and molybdenum (as examples of the nitrides of Groups III, IV, V and VI) are characterized by their remarkable stability at high temperatures.

Most nitrides react with water to liberate ammonia, as, for instance, $Mg_3N_2 + 6H_2O \rightarrow 3Mg(OH)_2 + 2NH_3$, although the tendency to do so depends not only on the specific nitride but also on

the method of preparation and the subsequent thermal history of the compound.

Thus, many of the nitrides prepared at lower temperatures by deammonation of the amides or imides hydrolyze rapidly; if these same nitrides are sintered by heating to a high temperature, they become relatively inert to attack by chemical agents (*e.g.*, boron nitride, BN). Structural changes to highly polymerized aggregates are involved. High-temperature treatment in some instances changes the composition of the nitrides to products of lower nitrogen content; *e.g.*, trititanium tetranitride, Ti_3N_4, is converted into titanium nitride, TiN.

Certain nitrides such as those of boron, BN, silicon, SiN, titanium, TiN, zirconium, ZrN, and tantalum, TaN, are extremely refractory materials with melting points near or above 2,500° C. Where this property is combined with chemical inertness such nitrides have found use in the manufacture of equipment that must withstand chemical action at high temperatures. Crucibles of titanium nitride are especially resistant to attack by various molten ferrous metals. The nitrides of titanium, zirconium and tantalum are furthermore characterized by their extreme hardness and are used either alone or in admixture with borides and/or carbides for hard-metal alloys and abrasive compositions.

Boron nitride has long been known to form hexagonal crystals that resemble graphite in structure and physical properties. Special experimental techniques entailing application of very high pressures (85,000 atm.) and high temperatures (1,800° C.) result in formation of the cubic form, known as "Borazon," which is as hard as the diamond but is more stable toward oxidation. (The patent literature must be consulted for specific disclosures concerning compositions used for such purposes.)

Formation of interstitial or metalliclike nitrides is involved in the nitriding process in which steel and its alloys are heated in an atmosphere of ammonia above 800° C. to produce a surface film possessing great hardness and resistance to wear and to chemical attack.

Mellor, *A Comprehensive Treatise on Inorganic and Theoretical Chemistry* (1922–37); H. J. Emeléus and J. S. Anderson, *Modern Aspects of Inorganic Chemistry* (1952). (L. F. A.)

NITRIDING, a process for the surface hardening of steel. It consists in heating special alloy steels in contact with ammonia at temperatures below the transformation range for steels, usually between 950° F. and 1,050° F., for periods of from 5 to 100 hr. depending upon the depth of hardened "case" desired. The steels used must contain nitriding-forming elements (such as aluminum, chromium or molybdenum) dissolved in the iron. During the nitriding cycle nitrogen from the ammonia diffuses into the steel and forms alloy nitrides, which are precipitated along the crystal planes of the iron. This precipitation causes an increase in hardness, which is dependent upon temperature and the amount and nature of the nitride-forming elements in the steel. Aluminum is the most effective hardening element. A steel containing approximately 1% aluminum and 1% chromium nitrided at 975° F. will have a surface hardness of approximately 1,100 Vickers-Brinell.

The advantages of nitriding compared with other methods of surface hardening are as follows: (1) A much harder and more wear-resistant case is produced. (2) Distortion is low primarily because the process is carried out below the transformation range. (3) The resistance to fatigue failures, particularly notch fatigue, is greatly increased because nitriding results in surface compressive stresses which resist crack formation. The disadvantages of the process are: (1) An alloy steel must be used, which is more expensive than plain carbon steels. (2) The time required to produce a case is long compared with other methods such as carburizing, cyaniding or induction hardening. (C. F. F.)

NITROBENZENE, the simplest aromatic nitrocompound, $C_6H_5NO_2$, was first isolated in 1834 by E. Mitscherlich and is prepared commercially by the action of a mixture of concentrated nitric and sulfuric acids upon benzene at a temperature of 50°–55° C. The oily product, which separates, is washed with alkali and then distilled. It is a highly poisonous yellowish liquid possessing a strong smell similar to that of oil of bitter almonds. It boils at 210.9° C. and melts at 5.7° C. The products of its electrolytic reduction vary with the conditions: in 50% sulfuric acid solution it yields *p*-aminophenol (L. Gattermann, 1893) in alkaline solution it yields azoxybenzene, azobenzene, hydrazobenzene or aniline, depending upon the material used for the cathode, upon the solvent, upon the applied voltage and current density and upon the total amount of current allowed to pass through the solution; in an approximately neutral aqueous or alcoholic solution, it yields β-phenylhydroxylamine; and, in acid alcoholic solution, it yields some benzidine together with other products. With chlorine, in the presence of iodine or antimony chloride, it yields meta-chloronitrobenzene. It occasionally acts as an oxidizing agent, as in the preparation of quinoline and fuchsin (magenta). It is used commercially for the preparation of aniline (*q.v.*) and of benzidine (*q.v.*), and in perfumery (oil of mirbane).
(G. W. Wn.)

NITROCELLULOSE (or cellulose nitrate) is the name given to the nitric esters of cellulosic materials, in practice largely cotton linters and wood pulp.

T. J. Pelouze discovered in 1838 that cotton could be converted into a violently inflammable substance by the action of concentrated nitric acid. C. F. Schönbein in 1845 demonstrated the use of this material as an explosive and improved the manufacturing method by adding sulfuric acid to the nitric acid. The form of nitrocellulose known as guncotton came into use as an ingredient of gunpowders (bulk powders) in the 1860s; gelatinized nitrocellulose propellants were introduced in the 1880s. E. A. Brown discovered in 1868 that dry and even moist nitrocellulose could be exploded by a detonator, thus starting the use of the substance as a high explosive.

The history of its uses is punctuated by many disastrous explosions, caused largely by the failure to appreciate that nitrocellulose is an unstable material and is subject to catalytic decomposition caused by its own decomposition products. This reaction, if not checked in time, results in explosions. Sir Frederick Abel demonstrated in 1868 that the then prevalent methods of washing nitrocellulose after nitration were inadequate and that the residual acid was causing high instability. The introduction of the pulping process and other changes in the washing procedure led to significantly improved nitrocellulose. However, explosions of smokeless powder magazines continued; and in modern practice, which goes back to the researches of Paul Vieille, special stabilizers are added to nitrocellulose; the function of these is to neutralize catalytically active decomposition products. The results of this are the modern stable and reliable propellants.

Cellulose molecules consist of thousands of anhydroglucose units, $C_6H_{10}O_5$, linked into chains; therefore the nitration process may be schematically represented by the equation:

$$C_6H_{10}O_5 + xHNO_3 \rightarrow C_6H_{10-x}O_{5-x}(NO_3)_x + xH_2O$$

Here x is a variable quantity which depends on the composition of the nitrating mixture and on the time and temperature of nitration. Theoretically x can reach the value of three, corresponding to 14.14% nitrogen in the product; but with mixtures of sulfuric and nitric acids such a high degree of nitration is seldom achieved.

The manufacture of nitrocellulose, in principle if not in practice, is a relatively simple process. Cotton linters or sulfite-process wood pulp are dipped into a large excess of nitric-sulfuric acid mixture; after a prescribed length of time, the product is separated from the bulk of the acid, for instance by centrifuging. The nitrocellulose is then "drowned" quickly in excess water and is subjected to boiling in acidified water to eliminate unstable byproducts of nitration.

The next step consists in pulping to disintegrate the fibres and to facilitate a subsequent washing, in which the last traces of acid must be removed. Cotton linters were for a long time preferred for the manufacture of gun propellants; but, starting in World War I, wood pulp became more and more accepted. A high content of alpha-cellulose in wood pulp appears to be essential

ensure high quality of smokeless powders.

Nitrocellulose is a fluffy, white substance, retaining some of the fibrous structure of untreated cellulose. It is rather unstable to heat and even carefully prepared samples will ignite on a brief heating to temperatures in excess of about 150° C.

Nitrocellulose is insoluble in water and in hydrocarbon solvents. It is soluble in acetone, in ethyl acetate, etc. Only the material with a low content of nitrogen is soluble in alcohol or ether, but intermediate grades are soluble in ether-alcohol mixtures.

Collodion or pyroxylin nitrocellulose, with a nitrogen content not in excess of 12%, is used chiefly for lacquers and celluloid plastics. Materials with a nitrogen content in the neighbourhood of 11.5% were used once, after denitration, as artificial silk, but have been replaced in this role by other materials, such as viscose rayon. This same material continued to be used for the manufacture of photographic films, although the use of safety film, made of cellulose acetate plastics, undermined its popularity.

Collodion nitrocellulose with 12% nitrogen finds much use in the manufacture of propellants and of gelatin dynamites. The highest degree of nitration which still gives a product soluble in mixed alcohol-ether solvents is 12.6%. This material, discovered by Dmitri Mendeleyev and known as pyrocellulose, is extensively used for the manufacture of propellants. Guncotton, with more than 13% nitrogen and soluble in acetone only, is also used for propellants, either alone or in combination with lower grades of nitrocellulose. Moist guncotton was once widely used as a high explosive, but it has been replaced by safer materials.

The nitration of cellulose is accompanied by a varying degree of depolymerization of the large molecules. For the manufacture of gun propellants the depolymerization is largely avoided, but with materials intended for the manufacture of lacquers it is deliberately encouraged since depolymerized nitrocellulose gives solutions of low viscosity which are desirable for this application.

NITRO COMPOUNDS. Organic compounds in which one or more hydrogen atoms are replaced by the nitro (NO_2) group are called nitro compounds. Two main classes are recognized: aromatic and aliphatic.

Aromatic Nitro Compounds.—Aromatic hydrocarbons are substances which contain only carbon and hydrogen and which have at least one benzene ring of six carbon atoms; the parent member of this group is benzene, C_6H_6. Replacement of a hydrogen atom by a nitro group produces an aromatic nitro compound; *e.g.,* from benzene, C_6H_6, nitrobenzene, $C_6H_5NO_2$, is obtained. Substitution of two or more hydrogens by a corresponding number of nitro groups is also possible. An important example is the replacement of three of the hydrogens of toluene, C_7H_8, which gives trinitrotoluene (TNT), $C_7H_5(NO_2)_3$.

Replacement of a hydrogen atom by a nitro group is known as nitration and is most commonly effected by treating the aromatic compound with a mixture of concentrated nitric and sulfuric acids. The equation for the nitration of benzene is

$$C_6H_6 + HONO_2 \rightarrow C_6H_5NO_2 + H_2O$$

For a long time it was thought that the sulfuric acid facilitated nitration by combining with the water formed, but this is now known not to be the case. Instead, the sulfuric acid, by reacting with the nitric acid, converts it into the nitronium ion, NO_2^+, and this is the actual nitrating agent.

Nitrations are carried out on a commercial scale in large cast-iron vessels equipped with devices through which cooling water can be circulated to remove the heat of reaction. As much as 1,000 gal. of benzene is nitrated at one time. As successive nitro groups are introduced into an aromatic compound, more drastic conditions must be employed. Thus, the preparation of TNT (*q.v.*) is usually carried out in three successive steps in each of which higher temperatures and stronger acids are used.

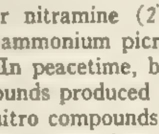
Many aromatic nitro compounds cause pronounced physiological reactions and care should be taken to avoid breathing their vapour and also to avoid contact with the skin. Aromatic nitro compounds are heavier than water and practically insoluble in it. Most are solids, although a few, including nitrobenzene, are liquids. Commercial preparations of nitrobenzene, trinitrobenzene and TNT usually have a yellowish colour, but the highly purified substances are colourless.

Nitrobenzene (*q.v.*) was first prepared in 1834 by E. Mitscherlich. Because of its characteristic odour it was called artificial oil of bitter almonds and was formerly employed as a flavouring principle and as an adulterant of oil of bitter almonds. It is highly toxic and such uses have been discontinued. Nitrobenzene was also used as a solvent for shoe dyes because it penetrates leather, but poisoning resulted by absorption of the vapours through the skin. Such formulations are now prohibited in most countries. Nitrobenzene is an excellent solvent for a wide variety of organic compounds.

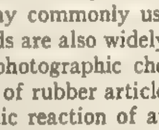
A number of polynitro aromatic compounds are used as explosives; *e.g.,* tetryl, or nitramine (2,4,6-trinitrophenylmethylnitramine); TNT; and ammonium picrate, a salt of picric acid (2,4,6-trinitrophenol). In peacetime, by far the major fraction of aromatic nitro compounds produced is converted into various derivatives. Aromatic nitro compounds are the starting point in the manufacture of many commonly used dyes. Derivatives of aromatic nitro compounds are also widely used as pharmaceuticals and to some extent as photographic chemicals and as chemicals used in the manufacture of rubber articles.

The most characteristic reaction of aromatic nitro compounds is reduction. A variety of reducing agents convert nitrobenzene, $C_6H_5NO_2$, into the aromatic amine aniline, $C_6H_5NH_2$. By use of milder reducing agents and control of the acidity or alkalinity of the reaction mixture, it is possible to stop the reduction at various intermediate stages. Consequently, a variety of compounds, in addition to amines, is readily available by controlled reduction of aromatic nitro compounds.

Aliphatic Nitro Compounds.—Aliphatic hydrocarbons contain only carbon and hydrogen and may be considered as derived from methane, CH_4. Replacement of a hydrogen atom by a nitro group gives aliphatic nitro compounds (commonly called nitroparaffins). Typical examples are: nitromethane, CH_3NO_2; 1-nitropropane, $CH_3CH_2CH_2NO_2$; 2-nitropropane,



and 2-methyl-2-nitropropane,



In contrast to the other hydrogen atoms, those hydrogen atoms attached to the carbon atom holding the nitro group are somewhat acidic; *i.e.,* they are removed under the influence of bases. The resulting salts are highly reactive, and many of the characteristic reactions of nitroparaffins proceed via these salts.

Nitroparaffins are classified as primary, secondary or tertiary. Primary nitroparaffins have two (or three) hydrogen atoms attached to the carbon holding the nitro group; *e.g.,* 1-nitropropane, nitromethane and nitroethane, $CH_3CH_2NO_2$. Secondary nitroparaffins have but one hydrogen atom on the carbon holding the nitro group, *e.g.,* 2-nitropropane, while tertiary nitroparaffins have no hydrogen atoms attached to the carbon holding the nitro group; *e.g.,* 2-methyl-2-nitropropane. Tertiary nitroparaffins do not react with bases and, hence, they fail to exhibit many of the common reactions of primary and secondary nitroparaffins.

Aliphatic hydrocarbons are much more resistant to direct nitration than the aromatic hydrocarbons, and because of this it was not until 1940 that nitroparaffins were produced commercially. The nitration of aliphatic hydrocarbons employs nitric acid alone and relatively high temperatures (300°–500° C.) are required. A

mixture of products results. For example, when propane, C_3H_8, is nitrated the products 1-nitropropane, 2-nitropropane, nitroethane and nitromethane are all formed. While satisfactory for the production of these simple nitroparaffins, the aliphatic nitration process is not suitable for the synthesis of higher members of the nitroparaffin series.

The reaction by which aliphatic nitro compounds were first prepared in 1872 is useful only for the synthesis of primary nitroparaffins. The synthesis of 1-nitrodecane is illustrative:

$$\underset{\text{1-bromodecane}}{CH_3(CH_2)_9Br} + \underset{\text{silver nitrite}}{AgNO_2} \rightarrow \underset{\text{1-nitrodecane}}{CH_3(CH_2)_9NO_2} + \underset{\text{silver bromide}}{AgBr}$$

In 1955 it was discovered that, contrary to the accepted view, if sodium nitrite ($NaNO_2$) is employed in place of silver nitrite, then the reaction is valuable for the production of primary and secondary nitroparaffins.

Tertiary nitro compounds are best obtained by oxidizing the corresponding amines with potassium permanganate ($KMnO_4$).

The lower nitroparaffins are colourless liquids of mild odour. In contrast with the aromatic nitro compounds the nitroparaffins have about the same toxicity as petroleum naphtha. The nitroparaffins are only slightly soluble in water. Boiling points of the four lowest members are: nitromethane, 101.2° C.; nitroethane, 114° C.; 2- and 1-nitropropane, 120.3° C. and 131.6° C.

The aliphatic nitro compounds are excellent solvents. They have also found use as fuels and as starting materials in synthesis.

A sensitized form of nitromethane is used as an explosive. Chloropicrin, $Cl_3C.NO_2$, is a grain fumigant, being especially effective against weevils. Chloropicrin is also a powerful lachrymator and this leads to its use as a tear gas and as a warning agent for other fumigants. Tetranitromethane, $C(NO_2)_4$, a colourless liquid, when mixed with organic compounds is liable to produce a violent explosion.

Nitroparaffins are readily reduced to amines; *e.g.*, nitroethane, $CH_3CH_2NO_2$, gives ethyl amine, $CH_3CH_2NH_2$. This reaction greatly extends the utility of the nitroparaffins by making numerous aliphatic amines readily available. *See* also BLASTING; EXPLOSIVES; NITROGLYCERIN; TNT. (N. KM.)

NITROGEN is a colourless, odourless, tasteless gas that is incombustible, does not support combustion or respiration, and is one of the most widespread elements. It occurs free in the atmosphere and also as an ingredient of various compounds, some of which are found in the proteins of plants and animals and others of which constitute important drugs, dyes and other chemicals. Symbol N, atomic number 7, atomic weight 14.0067. The free element consists of nitrogen molecules, N_2. Its existence was first recognized by C. W. Scheele (1772), who showed that common air is a mixture of two gases, which he called "foul air" (nitrogen) and "fire air" (oxygen). He obtained the foul air by removing the fire air in combination with various combustible or oxidizable materials, and showed that the residue would not support combustion or respiration. Nitrogen was discovered independently by Joseph Priestley and Daniel Rutherford about the same time. Antoine Lavoisier named the gas "azote" because of its inability to support life and recognized that it is an element. The name nitrogen was introduced by J. A. C. Chaptal (1790) to indicate that the element is a constituent of nitre (potassium nitrate, or saltpetre).

Nitrogen occurs in the atmosphere to the extent of approximately 78% by volume and 75.5% by weight, and serves to dilute the oxygen. Free nitrogen is also found in many meteorites, in volcanic gases and gases in mines and from some mineral springs; its presence in the sun and in certain stars and nebulae is shown by the spectroscope. In combination, it is found in nitre, Chile saltpetre (sodium nitrate), ammonia and ammonium salts in the atmosphere, in rain, soil and guano, and as complex organic compounds (proteins), with an average of 16% of nitrogen, in living organisms.

Preparation and Uses.—Nitrogen may be prepared (1) from atmospheric air by removal of the oxygen, or (2) from its compounds. Atmospheric nitrogen contains about 1% of group VIII-A gases (argon, etc.).

1. The oxygen is removed from air by exposure to phosphorus at ordinary temperature (burning phosphorus is not so effective), moist iron filings, an alkaline solution of pyrogallol, an acid solution of chromous chloride or cuprous chloride, or metallic copper in presence of hydrochloric acid or ammonia, or by passing air over red-hot copper.

On the large scale, nitrogen is made almost entirely by the fractional distillation of liquid air, in which process, since it has a lower boiling point than oxygen, it tends to evaporate first. The gas is marketed in gray cylinders under a pressure of about 120 atm. This gas contains most of the helium and neon present in air (*see* ATMOSPHERE), but the argon, which has nearly the same boiling point, mostly remains with the oxygen.

2. Pure nitrogen is made from its compounds: (*a*) by passing chlorine into ammonia solution, $2NH_3 + 3Cl_2 \rightarrow N_2 + 6HCl$; (*b*) by heating a solution of ammonium nitrite (or a mixture of sodium nitrite and ammonium chloride), $NH_4NO_2 \rightarrow N_2 + 2H_2O$; (*c*) by heating ammonium dichromate, $(NH_4)_2Cr_2O_7 \rightarrow N_2 + Cr_2O_3 + 4H_2O$; (*d*) by passing a mixture of nitric oxide and ammonia gas over red-hot copper, $6NO + 4NH_3 \rightarrow 5N_2 + 6H_2O$; (*e*) in a very pure state by heating sodium or barium azide in a vacuum, $Ba(N_3)_2 \rightarrow Ba + 3N_2$. The gas may be collected over water.

Nitrogen gas is used in filling the larger or cheaper kinds of electric bulbs (argon [*q.v.*] is used for the smaller, more expensive ones) to prevent blackening of the bulb by volatilized metal from the filament, which can thus be run at a higher temperature. High-temperature mercury thermometers may contain compressed nitrogen. Large quantities of nitrogen are used to make synthetic ammonia and other nitrogen compounds (such as nitric acid), which are needed in the production of dyes, drugs, explosives and fertilizers.

Properties.—Nitrogen gas is only slightly soluble in water but one volume of liquid oxygen dissolves about 450 vol. of the gas. On strong cooling under pressure, nitrogen forms a colourless liquid, boiling at −195.84° C., at which temperature its specific gravity is 0.8042. The critical temperature is −147.13° C. and the critical pressure 33.49 atm. On rapid evaporation under reduced pressure the liquid freezes to a colourless solid melting at −210.02° C. The density of nitrogen gas at 0° C. and 760 mm. pressure is 1.25051 g. per litre when gravity acceleration = 980.60 cm./sec.[1]

The element has two stable isotopes with masses 14 and 15, enrichment in N^{15} being achieved by an exchange reaction between ammonia gas and ammonium sulfate solution. Rutherford showed that the nitrogen atom is disintegrated by the impact of swift alpha particles, and protons (hydrogen nuclei) are expelled from its nucleus. Radioactive isotopes N^{13} and N^{16} are formed artificially in various ways; *e.g.*, N^{13} by bombarding carbon with deuterons.

Nitrogen gas is somewhat inert, since the heat of dissociation of the nitrogen molecule into atoms is large (170, or 225, kg.cal. per mole), but it can unite directly under certain conditions with several elements, including hydrogen, oxygen, boron, silicon, lithium, magnesium, calcium, barium, titanium, vanadium, tantalum, tungsten and manganese. The compounds with metals (nitrides) may be decomposed by water under various conditions, with evolution of ammonia.

Active Nitrogen.—When a current of nitrogen gas containing a trace of oxygen or other impurity is exposed at low pressure to a high-tension electric discharge, the gas beyond the discharge glows with a yellow light and is more active chemically than ordinary nitrogen (Lord Rayleigh, 1911). It does not react with molecular hydrogen or oxygen but forms ammonia with atomic hydrogen, combines with sulfur, phosphorus and several metals forming nitrides, decomposes nitric oxide into oxygen and nitrogen, and forms hydrocyanic acid with acetylene. The nature of this so-called active nitrogen is still uncertain, but it probably contains nitrogen atoms, both normal and excited. In a bulb coated with metaphosphoric acid, the glow persists for several hours.

The Nitrogen Cycle.—Animals derive the nitrogen of their

tissue proteins partly from animal proteins and partly (sometimes wholly) from vegetable proteins of food. Plants synthesize their proteins from inorganic compounds in the soil and to some extent from free nitrogen in the atmosphere. P. E. M. Berthelot found that sterilized soils do not take up nitrogen from the air, hence he concluded that microorganisms are concerned with the assimilation.

Leguminous plants such as peas, beans and clover can utilize atmospheric nitrogen by the action of a bacterium, *Rhizobium* (or *Pseudomonas radicicola*), of which there are several strains. The process takes place through the root hairs and involves the production of nodules on the roots, which contain Y-shaped associations of bacteria that are called bacteroids. Free-living anaerobic bacteria in the soil that are able to fix nitrogen are *Clostridium pasteurianum* (S. Vinogradsky, 1893) and *Azotobacter chröococcum* (M. W. Beijerinck, 1901). Certain algae also fix nitrogen and are of importance in tropical soils. The amount of nitrogen fixed by bacteria increases by 30% if certain protozoa are present in the soil, although protozoa feed on bacteria.

Ammonium salts in the soil are oxidized to nitrates by the agency of microorganisms, the process being called nitrification (S. Vinogradsky, 1890). They are first oxidized to nitrites by organisms belonging to the genera *Nitrosomonas*, and the nitrites are then oxidized to nitrates by another bacterium called *Nitrobacter*. The processes depend on free aeration and a neutral or alkaline reaction in the soil. The nitrate is assimilated but is reduced in the plant to ammonia.

Other kinds of bacteria decompose nitrogen compounds in the soil and, by this process of denitrification, return free nitrogen to the air. The combined nitrogen content of cultivated soil is generally enriched and renewed by means of nitrogenous fertilizers such as nitrates and ammonium salts.

Nitrogen is also fixed in the form of oxides by electrical discharges in the atmosphere, and conveyed to the soil in the form of nitric and nitrous acids by rain, these acids forming nitrates and nitrites in the soil. Altogether about 250,000 tons of nitric acid are said to be formed in this way in 24 hours. Some observations show, however, that the combined nitrogen content of rain does not increase during a thunderstorm.

Compounds of Nitrogen and Hydrogen.—Nitrogen forms three compounds with hydrogen, ammonia (*q.v.*), NH_3; hydrazine, N_2H_4; and hydrazoic acid or azoimide, HN_3. Ammonia and hydrazine normally function as bases and form secondary compounds, N_4H_4 and N_5H_5, respectively, with hydrazoic acid. With alkali metals, ammonia and hydrazine form compounds in which part of their hydrogen is replaced by a metal.

Hydrazine (*q.v.*), N_2H_4, with the structure $H_2N{\cdot}NH_2$ (diamide), was originally obtained by T. Curtius (1887) from organic compounds containing two nitrogen atoms linked together. It is made commercially by a process devised by Friedrich Raschig (1907). Sodium hypochlorite solution is mixed with a small quantity of glue and warmed with excess of concentrated ammonia. An intermediate compound called chloramine, NH_2Cl, is formed, which reacts with the excess of ammonia to form hydrazine. After addition of sulfuric acid and cooling, hydrazine sulfate, $2N_2H_4{\cdot}H_2SO_4$, crystallizes. When this is distilled under reduced pressure with concentrated potassium hydroxide solution, a colourless fuming liquid, called hydrazine hydrate, is obtained. From this, anhydrous hydrazine is obtained by distilling with solid sodium hydroxide or barium oxide (which remove water) under reduced pressure. It is a colourless liquid, boiling point 113.5° C., which freezes to a white crystalline solid, melting point 2° C. Hydrazine decomposes on heating, $3N_2H_4 \rightarrow N_2 + 4NH_3$, and reacts violently with halogens, forming nitrogen and halogen hydracids, $N_2H_4 + 2I_2 \rightarrow N_2 + 4HI$. Hydrazine rapidly destroys cork and rubber and when hot attacks glass. It is a weaker base than ammonia, forming two series of salts; *e.g.*, $N_2H_4{\cdot}HCl$ and $N_2H_4{\cdot}2HCl$. Hydrazine and its salts are poisonous. They are very powerful reducing agents, precipitating many metals from solutions of their salts.

Hydrazoic acid (*q.v.*), HN_3, also discovered by Curtius (1890), is formed by the action of an oxidizing agent, *e.g.*, nitric acid, on hydrazine, $3N_2H_4 + 5O \rightarrow 2HN_3 + 5H_2O$. The sodium salt is formed on passing nitrous oxide over heated sodamide, $NaNH_2 + N_2O \rightarrow NaN_3 + H_2O$. Pure hydrazoic acid is a colourless liquid (boiling point 37° C., melting point −80° C.), with a very unpleasant odour. It is very dangerously poisonous and explosive, decomposing with a blue flash on heating. The solution is acid and dissolves many metals, forming salts called azides, which, especially those of the heavy metals, are explosive; lead azide is used as a detonator instead of mercury fulminate. In its action on metals nitrogen is evolved (not hydrogen, except a trace with magnesium), and part of the acid is reduced to ammonia. With ammonia and hydrazine it forms the colourless crystalline compounds $NH_3{\cdot}HN_3$ (or N_4H_4) and $N_2H_4{\cdot}HN_3$ (or N_5H_5). The group $-N_3$ in hydrazoic acid behaves like a halogen; azides give a white precipitate of AgN_3 with silver nitrate. From X-ray spectra it is shown that the three nitrogen atoms in the group are in a straight line, not in a ring.

Oxides of Nitrogen.—The oxides of nitrogen are: nitrous oxide, N_2O; nitric oxide, NO; dinitrogen trioxide, N_2O_3; nitrogen dioxide, NO_2, and its polymer, dinitrogen tetroxide, N_2O_4; dinitrogen pentoxide, N_2O_5; and an unstable higher oxide of uncertain formula, perhaps NO_3.

Nitrous oxide, N_2O, was discovered by Joseph Priestley (1772) by exposing "nitrous air" (NO) to iron or alkali sulfides, when the gas diminished in volume and became a better supporter of combustion than common air. It was studied by Sir Humphry Davy (*q.v.*) (1799), who called it nitrous oxide and prepared it by heating ammonium nitrate, $NH_4NO_3 \rightarrow N_2O + 2H_2O$, the method now used. He showed that it has anesthetic properties, in some cases preceded by peculiar effects that led to its name "laughing gas." Nitrous oxide can be synthesized from its elements only with difficulty and under special conditions (D. L. Chapman, R. A. Goodman and R. T. Shepherd, 1926). It is produced by the reduction of nitric acid under certain conditions; *e.g.*, by the action of zinc on the dilute acid. It is made in the pure state by the action of hydroxylamine hydrochloride on sodium nitrite in equimolecular proportions in solution, hyponitrous acid being an intermediate product, $NH_2OH + HNO_2 \rightarrow N_2O + 2H_2O$. It is formed in special circumstances by the oxidation of ammonia.

Nitrous oxide is a colourless gas with a pleasant sweetish odour and taste, density 1.9777 g. per litre, 1½ times that of air. At 15° C. one volume of water dissolves 0.7778 vol. of nitrous oxide, forming a neutral solution. It is more soluble in alcohol (3.268 vol. at 15° C.). Nitrous oxide supports combustion better than common air (it kindles a glowing chip, like oxygen) because it decomposes into a mixture of one volume of oxygen and two volumes of nitrogen at a fairly low temperature (beginning at 520° C.). It is an endothermic compound; *i.e.*, contains more energy than its elements and can be decomposed into oxygen and nitrogen by the explosion of a detonator. The molecule is linear, the two nitrogen atoms being adjacent. On cooling or under pressure (50 atm. at 15° C.) it forms a colourless liquid, boiling point −88.7° C., on rapid evaporation of which a white solid, melting point −90.8° C., is formed. The critical temperature is 36.5° C. and the critical pressure 71.66 atm.

The chief use of nitrous oxide is as an anesthetic in operations of short duration, but prolonged inhalation of the pure gas causes death. About 22 l. is required to produce insensibility, and oxygen is usually administered as well. A very pure gas must be used; it is made by the decomposition of ammonia nitrate by heat, the temperature being carefully regulated to avoid the formation of ammonia and nitric oxide, and to minimize the formation of nitrogen. The gas is washed with solutions of ferrous sulfate and potassium hydroxide, and with milk of lime, and the gas is dried and liquefied by pressure in steel cylinders. One kilogram of ammonium nitrate gives 182 l. of the gas. Nitrous oxide also is used as a food aerosol.

Nitric oxide, NO, which is formed from its elements by the action of electric sparks or a high temperature, $N_2 + O_2 \rightarrow 2NO$, was first obtained by J. B. van Helmont about 1620, and R. Boyle

(1660), but was more carefully studied by Priestley (1772), who called it "nitrous air" and obtained it by the action of dilute nitric acid on copper or mercury, $3Cu + 8HNO_3 \rightarrow 3Cu(NO_3)_2 + 2NO + 4H_2O$. Copper turnings and a mixture of equal volumes of nitric acid and water may be used. The gas so prepared contains nitrogen and nitrous oxide. The pure gas is obtained by shaking a mixture of nitric acid and concentrated sulfuric acid with mercury, or by dropping a solution of sodium nitrite and potassium ferrocyanide into dilute acetic acid, $Fe(CN)_6^{4-} + NO_2^- + 2H^+ \rightarrow Fe(CN)_6^{3-} + NO + H_2O$, or by the action of sodium nitrite solution on an acidified solution of potassium iodide, $2NO_2^- + 2I^- + 4H^+ \rightarrow I_2 + 2NO + 2H_2O$. The colourless gas may be collected over water, or, if required pure, over mercury. It has a density of 1.3402 g. per litre, slightly greater than that of air. At 15° C., one volume of water dissolves only 0.051 vol. of the gas. It is not easily liquefied and has a boiling point of −151.7° C. and a melting point of −163.6° C. The liquid and solid are distinctly blue. The critical temperature is −96° C. and the critical pressure 64 atm. The molecule contains an odd electron in its structure, and nitric oxide is paramagnetic, its susceptibility being half that of oxygen.

Nitric oxide, although it is endothermic, is the most stable oxide of nitrogen, being dissociated into its elements only to about 3.5% at 1,000° C. Consequently, burning substances continue to burn in the gas only if they have previously attained a high temperature. A taper, burning sulfur or feebly burning phosphorus is extinguished, but brightly burning phosphorus burns brilliantly in the gas. A mixture of nitric oxide and carbon disulfide vapour burns with a brilliant lilac-coloured light, very rich in actinic rays. Nitric oxide combines rapidly with oxygen to form the dioxide, NO_2, which appears as red fumes when nitric oxide is exposed to air. The reaction involves three molecules, $2NO + O_2 \rightarrow 2NO_2$, and slows down appreciably in its later stages, so that a short time of contact is necessary for complete oxidation, and with dilute gases several minutes may be needed. This is important in technology (*see* NITROGEN, FIXATION OF). Nitric oxide dissolves to form a black liquid in cold ferrous sulfate solution but is expelled again on warming. The best solvent is a slightly alkaline solution of sodium sulfite, when the compound $Na_2(NO)_2SO_3$ is formed. At the temperature of liquid oxygen, it reacts with fluorine to form *nitryl fluoride*, $4NO + F_2 \rightarrow 2NO_2F + N_2$, a halogen derivative of nitric acid (melting point −166° C., boiling point −72.4° C.). The compounds NO_3F and NO_2Cl are also known. Nitric oxide and all higher oxides of nitrogen are poisonous.

Dinitrogen trioxide (nitrous anhydride), N_2O_3, was obtained by J. R. Glauber (1648). When nitric acid (56%) is distilled with arsenious oxide or starch, and the red vapour cooled in a freezing mixture, dark-blue liquid N_2O_3 is obtained, $2HNO_3 + As_2O_3 \rightarrow N_2O_3 + H_2O + As_2O_5$. On evaporation, the liquid decomposes almost completely into nitric oxide and nitrogen dioxide, but these recombine on liquefaction by cooling: $N_2O_3 \rightleftarrows NO + NO_2$. Although the gas is mainly a mixture of nitric oxide and nitrogen dioxide, only about 2% of N_2O_3 being present at 15° C., it is absorbed by solutions of alkalies with formation of nitrites, and by concentrated sulfuric acid with formation of nitrososulfuric acid ("chamber crystals"), thus behaving as if it consisted of N_2O_3. As absorption proceeds, the equilibrium is displaced to the left in the above equation. Only traces of nitrous acid are formed by the action of water, since the acid is unstable and decomposes, partly into dinitrogen trioxide (to which the blue colour of the solution is due) and water, and partly into nitric oxide and nitric acid: $3HNO_2 \rightarrow HNO_3 + 2NO + H_2O$. According to H. B. Baker and M. Baker (1900), when liquid dinitrogen trioxide is dried by long exposure to phosphorus pentoxide, the vapour formed from it consists of N_4O_6 molecules, but other workers could not repeat this experiment.

Sodium nitrite, $NaNO_2$, an important salt used in many organic preparations (*e.g.*, of dyestuffs), is mostly manufactured by absorbing higher oxides of nitrogen formed by the oxidation of ammonia in alkali solutions. Older methods of preparation are by heating molten sodium nitrate with metallic lead, $NaNO_3 + Pb \rightarrow NaNO_2 + PbO$, or by adding sulfur to fused sodium nitrate and sodium hydroxide, $3NaNO_3 + S + 2NaOH \rightarrow 3NaNO_2 + Na_2SO_4 + H_2O$. Nitrites are reducing agents, forming nitrates, usually in acid solution, but they also liberate iodine from acidified potassium iodide, being reduced to nitric oxide (*see* above).

The chloride of nitrous acid, *nitrosyl chloride*, NOCl, is a yellow gas formed by the direct combination of nitric oxide and chlorine, by the action of phosphorus pentachloride on sodium nitrite, by heating nitrososulfuric acid with sodium chloride, or (together with chlorine) by heating a mixture of concentrated nitric and hydrochloric acids (aqua regia): $HNO_3 + 3HCl \rightarrow NOCl + Cl_2 + 2H_2O$. It has been used for bleaching flour.

Nitrogen dioxide, NO_2, and *dinitrogen tetroxide*, N_2O_4, exist in equilibrium in varying proportions as a red gas, the mixture being sometimes called "nitrogen peroxide." The gas is formed by the direct union of nitric oxide and oxygen (*see* above). Nitrogen dioxide is usually prepared by heating dry lead nitrate, $2Pb(NO_3)_2 \rightarrow 2PbO + 4NO_2 + O_2$, and condensing the nitrogen dioxide to a liquid in a tube cooled in a freezing mixture, the oxygen passing on. A very pure gas is made by warming nitrososulfuric acid with potassium nitrate: $SO_2(OH){\cdot}O{\cdot}NO + KNO_3 \rightarrow KHSO_4 + 2NO_2$, or by adding fuming nitric acid and phosphorus pentoxide to liquid dinitrogen trioxide, and distilling: $N_2O_3 + N_2O_5 \rightarrow 2N_2O_4$. Dinitrogen tetroxide in a good freezing mixture solidifies to nearly colourless crystals (the liquid supercools), melting at −9.04° C. to a honey-coloured liquid. Both these forms consist mainly of N_2O_4. On warming, the liquid becomes red, because of formation of nitrogen dioxide molecules, $N_2O_4 \rightleftarrows 2NO_2$, and boils at 21.9° C. to form a red vapour. On heating, the colour of the gas deepens, because of further dissociation, and at 140° C. it is nearly black, dissociation being then complete. At still higher temperatures, nitrogen dioxide dissociates into nitric oxide and oxygen, this being complete at 620° C., when the gas is colourless, $2NO_2 \rightarrow 2NO + O_2$. On cooling, all these changes are reversed. Since the volume increases, the extent of dissociation may be calculated from the density of the gas. At atmospheric pressure it varies from about 15% at the boiling point to 89.3% at 100° C. and 100% at 140° C.

The gas kindles a glowing chip and supports the combustion of brightly burning phosphorus. A mixture with hydrogen is reduced to ammonia when passed over heated platinum. With water, the liquid, or gas, forms nitric and nitrous acids, $2NO_2 + H_2O \rightarrow HNO_3 + HNO_2$, and the nitrous acid decomposes (*see* above). With ice-cold water, blue liquid dinitrogen trioxide separates.

In the absorption of nitrous fumes in water, as in the preparation of nitric acid by the oxidation of ammonia, the evolution of nitric oxide necessitates adequate oxidation space for its reoxidation to nitrogen dioxide. Alkalies absorb the gas with formation of nitrite and nitrate, $2NO_2 + 2KOH \rightarrow KNO_2 + KNO_3 + H_2O$, the process being somewhat slower than in the case of dinitrogen trioxide. The liquid forms a violently explosive mixture with gasoline or other hydrocarbons. The gas diluted with air has been used in bleaching flour.

Dinitrogen pentoxide (nitric anhydride), N_2O_5, was discovered by H. E. Sainte-Claire Deville (1849) by the action of dry chlorine on warm silver nitrate, $4AgNO_3 + 2Cl_2 \rightarrow 4AgCl + 2N_2O_5 + O_2$. It is best prepared by adding phosphorus pentoxide to a cooled concentrated nitric acid, then distilling the product in a current of ozonized oxygen, drying the gas with phosphorus pentoxide and condensing in a receiver cooled in solid carbon dioxide and ether: $2HNO_3 + P_2O_5 \rightarrow N_2O_5 + 2HPO_3$.

It is also formed by passing ozonized oxygen into cooled liquid dinitrogen tetroxide: $N_2O_4 + O_3 \rightarrow N_2O_5 + O_2$. The colourless crystals are stable below 0° C., but are very hygroscopic. On warming they sublime, but if not quite pure they melt with some decomposition into nitrogen dioxide and oxygen, and also decompose on exposure to light. Rapid heating causes explosion. Phosphorus and potassium burn in the liquid on warming, and charcoal burns if previously ignited. With water, nitric acid is formed.

Trinitrogen tetroxide, N_3O_4, is said to be formed as a greenish solid by passing nitric oxide into liquid oxygen, or by the action of

air on solid nitric oxide at the temperature of liquid air. It decomposes into dinitrogen trioxide and nitric oxide above the temperature of liquid air (R. L. Hasche, 1925). A higher oxide of nitrogen, perhaps NO_3, is apparently formed by the action of an electric discharge on a mixture of nitrogen and oxygen, and has a characteristic absorption spectrum.

Hyponitrous acid, $H_2N_2O_2$, with the structure $HO{\cdot}N{=}N{\cdot}OH$, is formed by the action of nitrous acid on hydroxylamine (*see* above), but is best obtained as a salt by the reduction of a solution of sodium nitrite with sodium amalgam: $2NaNO_2 + 4Na + 2H_2O \rightarrow Na_2N_2O_2 + 4NaOH$ (Edward Divers, 1871). The free acid is obtained in colourless crystals, which at once decompose with feeble explosion, $H_2N_2O_2 \rightarrow N_2O + H_2O$, by the action of dry hydrogen chloride in ether on silver hyponitrite, and evaporation at room temperature. The acid and its salts are reducing agents. An isomer of hyponitrous acid is ***nitramide***, perhaps with the formula NH_2NO_2. *Oxyhyponitrous acid* (hyponitric acid, or nitrohydroscylamine), $H_2N_2O_3$, is known in the form of salts.

Nitrogen Halides.—*Nitrogen trifluoride*, NF_3, is a colourless gas, melting point $-208.5°$ C., boiling point $-129°$ C., formed by the electrolysis of ammonium hydrogen fluoride (O. Ruff and L. Staub, 1928). *Nitrogen trichloride*, NCl_3, is a yellow, very explosive oil, formed by the action of chlorine on ammonium chloride solution, or the action of excess of chlorine on ammonia (P. L. Dulong, 1811): $NH_3 + 3Cl_2 \rightarrow NCl_3 + 3HCl$. In the last reaction, two intermediate compounds are formed, viz., ***monochloramine***, NH_2Cl, which has been obtained pure in colourless crystals, melting point $-66°$ C., and ***dichloramine***, $NHCl_2$, known only in solution, formed by acidifying monochloramine solution. Nitrogen trichloride boils at 71° C., but easily decomposes with violent explosion on heating or shock. The vapour has a pungent smell and attacks the eyes and mucous membranes. The liquid explodes on exposure to bright light, and in contact with turpentine and with many solids. It is decomposed by ammonia. A solution in benzene is fairly stable. The vapour can be used in bleaching flour (agene process).

Nitrogen tribromide, NBr_3, and the compounds NH_2Br and $NHBr_2$ have been reported. *Nitrogen iodide* was obtained by B. Courtois (1812) as a black powder by the action of ammonia solution on iodine, and drying at room temperature on filter paper. Its formula is NI_3NH_3 (F. D. Chattaway, 1900). It is very explosive, detonating when gently pressed, with evolution of violet fumes of iodine. It is an oxidizing agent. *Nitrogen tri-iodide*, NI_3, is a black powder obtained by the action of ammonia gas on potassium iodobromide, $KIBr_2$, washing with water, and drying (H. W. Cremer and D. R. Duncan, 1930). *See* also AMMONIA; HYDRAZINE; HYDRAZOIC ACID; HYDROXYLAMINE; NITRIC ACID AND NITRATES; NITROGEN, FIXATION OF; and the references under "Nitrogen" in the Index.

NITROGEN, FIXATION OF. The term "fixation of nitrogen" has been given to any chemical process whereby "free" nitrogen, one of the elements, is caused to combine chemically with other elements to form nitrogen compounds. The atmosphere is a great reservoir of nitrogen, this element accounting for nearly four-fifths of the volume.

Nitrogen is chemically inert, and, under ordinary conditions, does not react with other elements. A number of rather drastic processes have been discovered for "fixing" nitrogen (*i.e.*, causing it to enter into chemical combinations) but these are processes one would not expect to find operative in nature. Yet, nitrogen in combined form is found in all fertile soils, in every living thing, in many foodstuffs, in silk, wool and feathers, in coal and in such naturally occurring chemicals as saltpetre and ammonia. Fixed nitrogen is found in the basic substance of living matter, the protoplasm; it is present in the nucleus of every living cell.

During the early decades of the 19th century, Nicolas Théodore de Saussure, Jean Baptiste Boussingault, Justus von Liebig and others demonstrated that growing plants obtain their fixed nitrogen from the soil. Animals, in turn, secure their fixed nitrogen through the consumption of plants or of other animals that use plants as food. The astonishing fact was discovered, however, that when crops were removed from a field, the decrease in the fixed-nitrogen content of the soil was less than the amounts accounted for by the crop removals. Liebig rightly concluded that the fixed-nitrogen supply of the soil was replenished from the atmosphere, but he contended that the process did not involve any fixation of free atmospheric nitrogen. Since he knew that rain water always contains traces of dissolved nitrogen compounds, and that both animal and vegetable matter release ammonia during decay, Liebig postulated that the released ammonia was returned to the earth in rain water. This "ammonia cycle," from earth to atmosphere and return to earth, does occur, but it accounts for only a small part of the fixed nitrogen that the soil receives from the atmosphere. Not until 1886 was it known that certain microorganisms are able to fix atmospheric nitrogen and thus replenish the soil's supply. Of these, the most important are the *Rhizobium* genera of bacteria and the *Azotobacter*. The former are found on the roots of leguminous plants and the latter live independently in the soil. In 1960 James E. Carnahan demonstrated that nitrogen is converted to ammonia by cell-free extracts of *Clostridium pasteurianum* in the presence of pyruvate.

In the mid-1960s, attention was focused on the function of pyruvate (*i.e.*, salts of pyruvic acid, such as sodium pyruvate). One of the tentative findings was that pyruvate can serve as a source of adenosine triphosphate (ATP) and at the same time act as a reducing agent. The enzyme or enzymes involved were not known, although it had been shown that ferredoxin (a protein) or methyl viologen (a dye) participate in electron transport.

(*See* also BACTERIA; LEGUMINOSAE: *Leaves and Roots;* NITROGEN: *The Nitrogen Cycle;* SOIL: *Nitrogen-Fixing Bacteria.*)

Although Liebig and his contemporaries did not arrive at a correct explanation as to the source of fixed nitrogen in the soil, they did make clear the importance of fixed nitrogen in agriculture. Nitrogenous materials long had been used as fertilizers although the reason for the beneficial effects was unknown. As a result of the new knowledge, ammonia released in making coke from coal was recovered and utilized as fertilizer, as was sodium nitrate from deposits in Chile. Wherever agriculture was practised intensively there developed a demand for nitrogen compounds to supplement the natural supply of the soil.

In addition to the demand for fixed nitrogen in agriculture, there were other urgent and growing needs for nitrogen compounds. The increasing quantity of saltpetre used in the manufacture of gunpowder led to a world-wide search for natural deposits of this nitrogen compound. Industrial demands and the advent of high explosives called for an ever-larger supply of fixed nitrogen. By the end of the 19th century it was clear that recoveries from the coal-carbonizing industry and the importation of Chilean nitrate could not meet future agricultural and industrial demands. Moreover, it was obvious that in the event of a major war a nation cut off from the Chilean supply soon would be unable to manufacture munitions in adequate amounts. It appeared that the fixation of atmospheric nitrogen offered the only solution. During the final decade of the 19th century and the opening decade of the 20th century, intensive efforts culminated in the development of commercial nitrogen fixation processes.

Fixation of Nitrogen as the Oxide.—Air is essentially a mixture of one volume of oxygen with four volumes of nitrogen. Both gases are in the free, or elemental, condition and do not react with each other under ordinary conditions. If, however, air or any other mixture of oxygen and nitrogen is heated to a very high temperature, a small portion of the mixture reacts to form the gas nitric oxide. On allowing the gas mixture to cool slowly, the nitric oxide decomposes almost completely into oxygen

and nitrogen. At any given temperature there exists a dynamic equilibrium among the three gases. This may be expressed chemically thus:

$$O_2 + N_2 + 43{,}200 \text{ cal.} \rightleftarrows 2NO$$

The arrows indicate that the reaction may proceed in either direction as conditions change. Although all chemical reactions are of this sort in theory, conditions are often such that the reaction proceeds almost exclusively in one direction. The chemical expression may then be written as an equation. In the reaction now under consideration, both the forward and reverse reactions must be taken into account. Change of pressure has no effect on the equilibrium, but when the temperature is increased the equilibrium shifts to the right; *i.e.*, a larger proportion of nitric oxide is formed. At ordinary temperatures practically no nitric oxide is present, but at the temperature of an electric arc a small percentage of nitric oxide is formed. Inasmuch as the nitric oxide decomposes into its elements on cooling, it would appear that an "arc" process could not serve as a commercial method of nitrogen fixation. It can serve as a practical process, however, when advantage is taken of the rates of the reactions involved. The chemical expression given above is for an equilibrium. It reveals nothing as to the time required to establish the equilibrium. It is well known that most chemical reactions are greatly accelerated as the temperature of the reactants is increased and, conversely, are retarded as the temperature is decreased. In the present case, equilibrium is reached quickly at the very high temperature of the arc. If the mixture of gases then is cooled rapidly, the rate of the reverse reaction drops to nil; *i.e.*, the decomposition of the nitric oxide virtually ceases, and the high-temperature equilibrium is, so to speak, "frozen."

The nitric oxide does not remain long as such in the cooled gas mixture but begins to react with the free oxygen present when the temperature falls below about 600° C., thus:

$$2NO + O_2 \rightleftarrows 2NO_2$$

The indicated reaction proceeds from left to right until nearly all the nitric oxide has been converted to the dioxide, NO_2. The latter polymerizes partially to set up another equilibrium, thus:

$$2NO_2 \rightleftarrows N_2O_4$$

And, when the $NO_2-N_2O_4$ mixture is brought into contact with water, nitric acid is formed. (*See* also NITRIC ACID AND NITRATES.)

The foregoing facts form the basis for a practical process of nitrogen fixation.

In 1772 the English chemist Joseph Priestley observed that the passage of an electric spark through a small volume of air confined over water brought a decrease in gas volume, and that the water became acidic. Priestley did not interpret this result correctly and two years elapsed before the correct interpretation was given by another English chemist, Henry Cavendish. Thus was discovered what later became known as the "spark" or "arc" method of nitrogen fixation. At that time, however, electrical energy was far too costly to permit the use of such a process.

By the end of the 19th century, mechanical means of generating large quantities of electric energy had been evolved, and the use of water power to drive electric generators finally brought the cost of electric energy down to a range where nitrogen fixation by the spark or arc method became economically feasible. Many experimenters then turned attention to the problem, and by 1902 Charles S. Bradley and D. R. Lovejoy had a small plant using a spark process in operation at Niagara Falls, N.Y. This venture failed commercially, however. In 1904 Christian Birkeland of Oslo, Nor., and Samuel Eyde, an engineer, used an arc method in a small plant that was the forerunner of large and commercially successful plants. In 1908 a large arc process plant was established at Notodden, Nor. In the Birkeland-Eyde process an electric arc was spread into a disk of flame by means of a magnetic field. Air was blown through the disk and then mixed immediately with cold air, thus "freezing" the high-temperature equilibrium.

Several modifications of the arc process were developed in the first two decades of the 20th century, and small plants were built in countries other than Norway. The arc process was, however, inherently inefficient in the use of energy, and the absorption towers required for the reaction of the nitrogen oxides with water were large and costly. Better methods of fixing nitrogen were soon discovered and the process was eventually abandoned.

In the decade 1940–50 new interest was aroused in the fixation of nitrogen as the oxide through the use of the high temperature and rapid heat exchange and heat economy possible in a "Royster stove." This piece of equipment is a modification of the heat-exchange stoves long in use on blast furnaces, the essential difference being the substitution of small pieces of highly refractory material for the usual brick checkerwork in the stoves. In the process two or more Royster stoves are used. The refractory filling in one such stove is brought up to a high temperature by burning gas therein. Air is then passed through the stove and, at the high temperature prevailing, a small portion of nitric oxide is formed. The high-temperature equilibrium is then "frozen" by passing the hot gas into an unheated stove. The nitric oxide in the cool gas issuing from the second stove may then be recovered. When most of the heat in the first stove has been transferred to the second stove, the direction of air flow through the two stoves is reversed. Inasmuch as the heat transfer between the two stoves cannot be quite complete without disturbing conditions necessary in the process, one stove must be reheated occasionally with gas.

Fixation of Nitrogen as a Cyanide.—Another chemical method of fixing nitrogen was discovered about 1828 by Desfosses, who observed that potassium cyanide was formed when a stream of nitrogen was passed through a red-hot mixture of potash and carbon in an iron tube. In 1842 a small plant using the cyanide method was built in France and was operated for a few years. Many other attempts were made to find a practical process based on cyanide formation, the latest during World War I, but no commercially successful cyanide process had been adopted at mid-20th century.

Fixation of Nitrogen as a Nitride.—At high temperatures nitrogen will combine directly with some metals to form their nitrides (*q.v.*), most of which can be hydrolyzed to form the metal hydroxides and ammonia. During the decade 1909–19, unsuccessful attempts were made to apply a nitride process developed by O. Serpek in which nitrogen, aluminum oxide and carbon were heated together to form aluminum nitride.

Fixation of Nitrogen as a Cyanamide.—During the period 1895–98, Adolph Frank and Nikoden Caro conducted investigations directed toward the improvement of methods for producing cyanides. In the course of this work they discovered that crude calcium carbide and nitrogen would react at 1,000° C. to form calcium cyanamide rather than a cyanide. The chemical reaction may be written thus:

$$CaC_2 + N_2 \rightarrow CaCN_2 + C$$

Pure carbide reacts slowly, if at all, but the reaction is catalyzed by alkalies or alkaline earths. Calcium fluoride is the catalyst commonly used. Crude calcium cyanamide may be used directly as a fertilizer.

A large calcium cyanamide plant was built in Italy in 1907. Within the next five years, large plants were built in Germany, Dalmatia, France, Switzerland, Norway, Canada and Japan. The cyanamide process was the first nitrogen fixation process to be so widely used. During World War I the United States government built a very large cyanamide plant near Wilson dam, Alabama.

Calcium carbide and nitrogen are the raw materials for the cyanamide process. The nitrogen may be obtained by the partial liquefaction and fractional distillation of air. The carbide is made by the heating of coke and high-grade lime in an electric furnace, the chemical reaction being:

$$CaO + 3C \rightarrow CaC_2 + CO$$

The carbon monoxide gas escapes from the furnace. The carbide is drawn off in molten form, cooled, ground and then heated to 1,000° C. and treated with nitrogen. The nitrifying reaction is exo-

thermic and continues spontaneously once started. The resultant mass of crude cyanamide is cooled, ground and granulated for use as a fertilizer, or the cyanamide may be hydrolyzed and the fixed nitrogen liberated as ammonia: $CaCN_2 + 3H_2O \rightarrow CaCO_3 + 2NH_3$.

The cyanamide process is an elaborate one. The electric energy required to produce the necessary carbide is relatively large per ton of fixed nitrogen finally obtained, although it is not so large as the energy required in the arc process.

The development of new manufacturing processes has been rapid during the 20th century. Within a decade after the erection of the first plant using the arc process, that process was fast becoming obsolete, and the cyanamide process was also to become obsolete within a decade after its development. Subsequent to World War I, no new cyanamide plants were built, although some of those then extant were still in operation at the beginning of World War II.

Fixation of Nitrogen as Ammonia.—The direct synthesis of ammonia from elemental nitrogen and hydrogen has proved to be the most economical method discovered for the fixation of nitrogen. This method is being utilized in many countries and has become one of the largest and most basic processes of chemical industry the world over.

During the closing decade of the 19th century and the early years of the 20th century many investigators studied the gaseous system nitrogen-hydrogen-ammonia. Among those prominent in this work in the period 1904–08 were Fritz Haber (*q.v.*), G. van Oordt, R. LeRossignol, W. Nernst, F. Jost and K. Jellinek.

The research of Haber and his associates convinced the Badische Anilin- und Sodafabrik that it was economically feasible to manufacture ammonia. The German firm then threw its great engineering and technical resources into the project and in 1910 a pilot plant was put into operation. This was the forerunner of a commercial plant that began production in 1913 with a capacity of 7,000 tons of fixed nitrogen per year.

It was well known when Haber and his associates began their research on ammonia synthesis that no ammonia is formed when nitrogen and hydrogen are brought together under ordinary conditions of temperature and pressure. It was known that a trace of ammonia is formed when a silent electric discharge is passed through a mixture of nitrogen and hydrogen. It had also been observed that complete decomposition of ammonia cannot be effected by heat. Regardless of these clues to the existence of a true equilibrium, such as represented by the expression

$$N_2 + 3H_2 \rightleftarrows 2NH_3 + 24{,}000 \text{ cal.},$$

several investigators of note contended that no such equilibrium could be found. The situation was, therefore, one of confusion until Haber and his co-workers clearly demonstrated the existence of the equilibrium and measured the concentrations of the gases under several conditions of temperature and pressure.

Inasmuch as the foregoing expression of equilibrium indicates that one volume of nitrogen and three volumes of hydrogen combine to form two volumes of ammonia, it follows, according to the Le Chatelier principle (*see* LE CHATELIER, HENRY LOUIS), that the higher the pressure on the system the larger the proportion of ammonia at equilibrium; that is, the equilibrium is shifted toward the smaller volume. It will be recalled that this effect of pressure is different from the case of the nitrogen-oxygen-nitric oxide equilibrium, on which a change in pressure had no effect. The effect of temperature on the equilibrium in the two cases is reversed. In the nitrogen-oxygen-nitric oxide equilibrium the higher the temperature the larger the proportion of nitric oxide, whereas in the nitrogen-hydrogen-ammonia equilibrium the higher the temperature the smaller the proportion of ammonia.

The table shows the effect of temperature and of pressure on the percentage of ammonia formed at equilibrium when one volume of nitrogen and three volumes of hydrogen are caused to react. From the table it is apparent that an ammonia synthesis process should be carried out at a temperature as low and at a pressure as high as may be practical and economical. Again, the rates of reaction toward equilibrium must be taken into account. At

Percentage of Ammonia at Equilibrium
(Data obtained by the U.S. Fixed Nitrogen Research Laboratory)

Temperature ° C.	Pressure in atmospheres						
	10	30	50	100	300	600	1,000
200 . . .	50.66	67.56	74.38	81.54	89.94	95.37	98.29

550 . . .	0.76	2.18	3.45	6.82	19.13	31.63	41.16
600 . . .	0.49	1.39	2.26	4.52	13.77	23.10	31.43
650 . . .	0.33	0.96	1.53	3.11	9.92	16.02	20.70
700 . . .	0.23	0.68	1.05	2.18	7.28	12.60	12.87

ordinary temperatures the rate of reaction is virtually zero and is negligibly low even at 500° C. unless a catalyst is used. Obviously, the use of a catalyst in ammonia synthesis is extremely important in permitting the reaction to be carried out at a lower temperature than would be practical with no catalyst. In commercial plants temperatures in the range 450° C. to 500° C. are used. The best catalyst known is prepared from pure iron plus small proportions of alumina and potash. The decision as to the pressure at which to carry out the ammonia synthesis is an economic matter. Plants have been built to operate at pressures as low as 100 atm. and as high as 1,000 atm., but most of the plants use pressures in the range 200 to 350 atm. (*See* also CATALYSIS: *Heterogeneous Catalysis*; CHEMICAL EQUILIBRIUM.)

Steps in the Synthetic Ammonia Process.—Four major steps are involved in the synthetic ammonia process as it is carried out in large commercial plants. The initial step comprises the preparation of nitrogen and hydrogen or a mixture of these two gases. Where natural gas is available at relatively low cost, this material is used as a source of hydrogen. Most of the plants, however, use air, steam and coke (or natural gas) to obtain a mixture of nitrogen and hydrogen along with carbon monoxide, carbon dioxide and other impurities. This mixture is then further processed with steam to convert most of the carbon monoxide to hydrogen and carbon dioxide. A few plants obtain hydrogen through the electrolysis of water, and a few others use coke-oven gas as a source of hydrogen. In all plants the necessary nitrogen is obtained from air.

In the second step of the process, the gas mixture is compressed and then freed from undesired gases by means of an elaborate system of equipment, leaving a purified mixture of nitrogen and hydrogen in the correct proportion for the ammonia synthesis.

In the third major step the nitrogen-hydrogen mixture is passed through a bed of catalyst at a temperature of about 500° C. and at a pressure from 100 to 1,000 atm. Some ammonia is thus formed, the proportion depending on the temperature and pressure used, the activity of the catalyst and time of contact of the gases with the catalyst.

In the fourth and final step the ammonia is removed, usually by refrigeration. The part of the gas mixture that remains uncombined is then recycled through the catalyst bed after the addition of sufficient fresh nitrogen-hydrogen mixture to compensate for the ammonia removed from the system.

Although the synthetic ammonia process may seem to be one of relative simplicity, it actually represents engineering achievement in the usage of materials and in construction unknown before the 20th century. Nevertheless, the process assures ample supplies of ammonia, which has become the cheapest form of fixed nitrogen available to industry and to agriculture, and is the raw material from which numerous nitrogenous chemicals are manufactured.

The success of the synthetic ammonia plants built in Germany during World War I led to a rapid expansion of the industry and the construction of plants in many countries other than Germany. The initial plant at Oppau, Ger., was expanded to a capacity of 120,000 tons per year during World War I and a second large plant built at Leuna, near Merseburg. Various modifications of the original Haber or Haber-Bosch process were devised, such as the Claude process in France, the Casale process in Italy, the American and the Nitrogen Engineering processes in the United States. During World War II ten new synthetic ammonia plants

were built in the U.S. to meet an anticipated demand for ammonia in the production of munitions. The output of some of these plants was diverted to the production of agricultural fertilizer in the form of ammonium nitrate. At the close of World War II most of the German synthetic ammonia plants lay in ruins; the United States had become the world leader in ammonia production, with a fixed nitrogen capacity of more than 1,000,000 tons per year. *See* also CHEMICAL INDUSTRY: *Haber Ammonia Process;* FERTILIZERS AND MANURES: *Nitrogen Fertilizers.*

NITROGEN HARDENING: *see* NITRIDING.

NITROGLYCERIN (GLYCERYL TRINITRATE) is a powerful explosive and an important ingredient of most dynamites. It is used also (with nitrocellulose) in some propellants, especially for rockets and missiles, and as a vasodilator in the easing of cardiac pain such as occurs in angina pectoris.

Properties.—Nitroglycerin is a heavy, oily liquid that is colourless when pure but usually is pale yellow in the commercial grades. Its specific gravity is 1.60 at 15° C. The chemical formula is $C_3H_5N_3O_9$ and the structural formula is $CH_2(ONO_2)$-$CH(ONO_2)$-$CH_2(ONO_2)$; the positive oxygen balance (*i.e.*, more than enough oxygen atoms are available for oxidizing the carbon and hydrogen atoms while nitrogen is being liberated) and the high nitrogen content (18.5%) account for the fact that nitroglycerin is one of the most powerful explosives known.

$$4C_3H_5(ONO_2)_3 \rightarrow 6N_2 + 12CO_2 + 10H_2O + O_2$$

Thus one pound (0.454 kg.) of nitroglycerin produces 156.7 cu.ft. (about 4,437 l.) of gas. The resulting detonation wave moves at approximately 7,700 m. per second; this compares with a rate of less than 7,000 m. per second for TNT (trinitrotoluene). Nitroglycerin is extremely sensitive to shock and to rapid heating; it begins to decompose at 50°–60° C., is significantly volatile at 100° C. and explodes at 218° C. It is only slightly soluble in water and in glycerol, is fairly soluble in ethyl alcohol and methyl alcohol, and is miscible in all proportions with ether, acetone, benzene, etc.

Preparation.—Nitroglycerin, the nitric acid triester of glycerol, was first prepared in 1846 by A. Sobrero by adding glycerol (glycerin) to a mixture of concentrated nitric and sulfuric acids at 10° C. or below. The main function of the sulfuric acid is to absorb the water formed in the chemical reaction. Continuous manufacturing processes developed in the 1940s by Mario Biazzi and others came to be widely used. These processes offer greater safety than older methods because the reactants and the explosive final product (nitroglycerin) literally trickle through the apparatus, rather than being concentrated in a large nitrator charge.

Uses.—The comparatively safe use of nitroglycerin as a blasting explosive became possible after Alfred B. Nobel developed dynamite in the 1860s. He mixed liquid nitroglycerin with an absorbent nonexplosive material such as charcoal or kieselguhr (diatomaceous earth), with more active sodium nitrate (and an absorbent) or even with nitrocellulose. The nitroglycerin gelatinizes the nitrocellulose to produce blasting gelatin, a very powerful blasting agent. Nobel's discovery of the ability of nitroglycerin to gelatinize nitrocellulose led to the development of ballistite, the first double-base propellant and a precursor of cordite; both ballistite and cordite contain 30%–40% of nitroglycerin. Similar double-base formulations are used extensively in rocket and missile propellants and in some gun propellants.

A serious problem in the use of nitroglycerin as an explosive is its relatively high freezing temperature (13.2° C., or 56° F.). This disadvantage is avoided by using nitrated mixtures of glycerol and closely related polyhydric alcohols such as ethylene glycol ($HOCH_2$-CH_2OH). For example, the eutectic nitrate mixture composed of 71% ethylene glycol dinitrate and 29% nitroglycerin has a freezing point of −29° C., compared with the 13.2° C. for nitroglycerin alone.

Biologic Effects.—Nitroglycerin has a sweet, burning taste and is somewhat poisonous; its vapour is absorbed readily through the skin and produces violent headaches, but repeated exposures reduce this effect to nil. Taken orally, usually as a sublingual tablet, it relaxes the smooth muscles of the blood vessels; hence it is administered to relieve or prevent cardiac pain.

(B. E. AN.)

NITTI, FRANCESCO SAVERIO (1868–1953), Italian statesman, a left-wing Liberal who was prime minister for a critical year after World War I (*see* ITALY: *History*), was born at Melfi (Potenza) on July 19, 1868. He became a barrister and professor of public finance at the University of Naples and then entered parliament in 1904. He was minister of agriculture, industry and trade in Giovanni Giolitti's fourth cabinet (March 1911–March 1914) and minister of the treasury in V. E. Orlando's first cabinet (Oct. 1917–Jan. 1919). Four days after the fall of Orlando's second ministry (June 19, 1919) Nitti himself became prime minister. His adoption of the system of proportional representation (Aug. 15, 1919) resulted in an important increase in the Socialist and Christian Democratic (Popolari) deputies at the elections on Nov. 1919, but he failed to conciliate either group. An epidemic of strikes and disorders caused by the Communists, the Nationalists and the Fascists weakened his position, and on June 9, 1920, he finally resigned. Nitti was reelected to parliament in May 1921, but did not stand in the elections of April 1924, held under Mussolini's regime. He left for Switzerland, but from 1925 lived in Paris. During World War II he was arrested by the Germans in Aug. 1943 and interned in Austria. Freed in April 1945, he returned to Italy and attempted to reenter politics. In June 1948 he became a *de jure* member of the Italian senate. He died in Rome on Feb. 20, 1953.

Nitti published several books on economic and political questions. The best known was *L'Europa senza pace* (1921, Eng. trans. 1922), followed by *La Decadenza dell'Europa* (1922; Eng. trans. 1923), in which he recommended a radical revision of the treaty of Versailles. He also left memoirs: *Meditazioni dell'esilio* (1947) and *Meditazioni e ricordi* (1953).

NIVELLE, ROBERT GEORGES (1856–1924), commander in chief of the French armies on the western front for five months in World War I, whose career was wrecked by the failure of his prescription for a prompt and decisive victory, was born at Tulle on Oct. 15, 1856. An artilleryman who had passed through the École Polytechnique and the École Supérieure de Guerre, he served in Indochina and in Algeria. During the first phases of World War I he was in France commanding a brigade in 1914 and an army corps by the end of 1915. On May 2, 1916, he was appointed to command the 2nd army at Verdun, succeeding Gen. Pétain at the height of the battle. Nivelle inspired in October and December two French counterattacks which proved to be dazzling successes. The government and nation, despondent at France's great losses and small reward during the year, saw Nivelle as the man of the hour. Gen. Joffre, who had commanded the French armies since the beginning of the war, was removed, and

on Dec. 12 Painlevé, the French premier, promoted Nivelle over the heads of many seniors to take his place.

Nivelle at once proclaimed that the methods he had perfected at Verdun could win the war. He expounded the theory of great violence, particularly of artillery, allied with great mass. So enthusiastic was Lloyd George, the British prime minister, that he placed the British armies in France under Nivelle's command for his great offensive. Yet despite this backing and despite the brilliant success of the British diversionary attack at Arras, Nivelle steadily lost the confidence of his own chief subordinates and finally that of his government. The German retreat to the Hindenburg line disorganized the northern sector of his attack, but on April 16, 1917, in dreadful weather, he launched his offensive on the remaining sectors. His preparations failed to master the German defense in depth; and though the French took 20,000 prisoners and 147 guns in less than a week, they utterly failed to break through the German lines. The next month witnessed the outbreak of widespread mutinies in the French armies. On May 15, 1917, Nivelle was replaced by Pétain as commander in chief; and in December 1917 he was transferred to North Africa. He retired in 1921 and died in Paris on March 23, 1924. *See* also World War I: *The Penultimate Year.*

NIVERNAIS, in France under the *ancien régime,* was the country administered from Nevers (*q.v.*). The province was bounded southwest by Bourbonnais, west by Berry, north by Orléanais, and northeast, east and southeast by Burgundy. Detached from Burgundy by the end of the 10th century, the countship of Nevers was held by the male descendants of Count Landry (d. 1028) till 1181; passed through marriages to the house of Dampierre, counts of Flanders, in 1280; went as part of the Flemish inheritance to a junior branch of the house of Burgundy in 1405; and was inherited by a junior branch of the house of Cleves in 1491. It was made a duchy of France in 1539. By marriage (1566), the duchy came in 1601 to a branch of the house of Gonzaga, which sold it to Cardinal Mazarin in 1659. Mazarin left it to his nephew Philippe Julien Mancini, whose descendants held it till the French Revolution as the last great fief still not reunited to the French crown. In 1790 most of Nivernais became the *département* of Nièvre.

NIXON, RICHARD MILHOUS (1913–), 36th vice-president of the United States, was born at Yorba Linda, Calif., Jan. 9, 1913, of Quaker parents. He graduated in 1934 from Whittier College, California, where he specialized in constitutional history, and from Duke University Law School, Durham, N.C., in 1937. Nixon practised law in Whittier for five years and, after serving as attorney in the Office for Emergency Management in Washington, D.C., January–August 1942, was commissioned lieutenant, junior grade, in the U.S. Navy; he left active service in 1946 as lieutenant commander.

Nixon was elected a Republican representative of the 12th congressional district of California in November 1946, unseating the veteran Democratic incumbent, H. Jerry Voorhis, after a series of joint platform discussions reminiscent of the Lincoln-Douglas debates. He was returned to Congress unopposed in 1948.

HENRI CARTIER-BRESSON FROM MAGNUM

RICHARD NIXON

In the house of representatives he helped draft the Taft-Hartley Labor Relations Act and played a prominent role in preparing the congressional investigation of Alger Hiss, a former state department official later convicted of perjury in connection with Communist espionage. In November 1950 Nixon defeated Helen Gahagan Douglas and became U.S. senator from California. He was nominated by the Republican national convention of 1952 as the vice-presidential running mate of Dwight D. Eisenhower and elected by a decisive margin. The campaign opened with charges that Nixon had illegally benefited from a private fund raised by his supporters. In answer to demands that he withdraw from the race, Nixon made a dramatic and successful defense in a nationwide television broadcast.

As vice-president Nixon became a leading spokesman of the Eisenhower administration, presiding over meetings of the cabinet and of the National Security Council in the president's absence. He and his wife also traveled throughout the world and were generally well received, although the vice-president was the victim of mob violence and threat of assassination in Caracas, Venez., in May 1958. On the occasion of Nixon's presence at the official opening of the first American exposition in Moscow, in July 1959, he engaged in a celebrated "kitchen debate" with Nikita Khrushchev. Nominated for the presidency at the 1960 Republican convention, Nixon campaigned vigorously but was defeated by a small margin in the November election by his Democratic opponent, Sen. John F. Kennedy of Massachusetts. In 1962, running for governor of California, Nixon was defeated by the incumbent, Edmund G. Brown. Nixon wrote *Six Crises* (1962), a personal account of the turning points of his political career. He moved to New York in 1963 and practised law there, but remained active in Republican Party affairs.

NIZA, MARCOS DE (Fray Marcos) (*c.* 1495–1558), Italian Franciscan friar who reached the "seven cities" of the Zuñi (*q.v.*) Indians in western New Mexico in 1539, was born in Nizza (Nice) about 1495. He went to America in 1531 and served in Peru, Guatemala and Mexico. He was sent to Culiacán (at 24° N. in Mexico) and there freed Indian slaves from regions to the north. Later he was sent on an advance party under the Negro Esteban to cross the deserts to the stone-built cities of Cibola where Esteban was killed. Marcos claimed to have come within sight of the cities but then returned in haste and fear. From Indian reports made to please him he described large towns with precious stones, gold and silver, but F. V. de Coronado in 1540 found them to be small and poor. Marcos was made provincial of his order for Mexico in 1541. He died in Mexico on March 25, 1558.

His journey and the killing of Esteban reveal that Spanish slave raids north of Culiacán and the treatment of Indian women by the Spaniards had antagonized lands far to the north of those reached by Spaniards, and were a factor in limiting Spanish settlement to Mexico for a long time.

NIZAMABAD, a town and district of Andhra Pradesh, India. The town, formerly known as Indur, is the headquarters of the district, and lies 90 mi. N.N.W. of Hyderabad on the Hyderabad-Godavari valley line of the Central railway. Pop. (1961) 79,093. The fort on a hill to the southwest was originally a temple where a tank (reservoir) was built, now forming a source of water supply. The remains of a great fortified temple, known as the fort of Indur, also to the southwest, have been converted into a jail and college of arts and science. There are two old and richly carved Jain temples at nearby Yellareddipet. Industries include rice husking, khandsari sugar processing and the production of reinforced concrete water pipes.

Nizamabad District (area 3,105 sq.mi.; pop. [1961] 1,022,013) is bounded north by the Godavari river (which separates it from Adilabad district) and west by the Manjira, a tributary of the Godavari (which separates it from Nanded district). The climate is hot and slightly humid. The average annual rainfall is about 45 in. Rice, jowar, wheat, sugar cane and pulses are the principal crops. The Nizam Sagar project provides better irrigational facilities for large-scale production of sugar cane and rice; its reservoir was constructed by damming the Manjira. The dam, stretch-

ing across the two arms of the river, is more than 2 mi. long and carries an 84-ft.-wide motorable road. The main canal, 100 ft. wide and 10½ ft. deep, falls into a small lake, Ali Sagar, which, with its rugged mountain scenery, gardens and rest house, is a pleasant tourist resort. The district has large tracts of forests yielding valuable timber. At Bodhan, 16 mi. W. of Nizamabad town, are large sugar and alcohol factories, and at Kamareddy (southeast) is another alcohol factory. Armur, to the north, is known for its artificial silk cloth. There is a Christian mission hospital for lepers and a Vishnu temple at Dichpally. (S. AH.)

NIZAM AL-MULK ("Orderer of the Kingdom"; ABU ALI HASAN IBN ALI) (1018–1092), minister successively to Alp Arslan and Malik Shah (*qq.v.*), the great Seljuk rulers of Iran, was born, probably on April 10, 1018 (one authority has 1019/20), at Radkan near Tus in Khurasan. The Seljuks supplanted the Ghaznevids as rulers of Iran in 1040 and some time thereafter Nizam entered the service of Alp Arslan. By 1059 he was vizier of Khurasan. His fortunes rose with his master's and when Alp Arslan became sultan Nizam al-Mulk assumed charge of the whole administration. He also took part in military operations, being charged with reducing the rebellious province of Fars in 1067. As a great Iranian vizier he conspicuously exemplifies the chief minister's role of mediator between a despot, in this instance an alien Turk, and his Persian subjects. He kept Turkmen immigrants, who had entered Iran with the Seljuks, engaged in hostilities outside the country; he enhanced the dignity and prestige of the Seljuks by inculcating canons of royal behaviour and etiquette; and he tempered military harshness with lessons in judicious clemency and conciliation. He built up Seljuk power with the sultan as the keystone in an integrated administration and encouraged the recognition of local rulers as honourable vassals.

On Alp Arslan's death in 1073 Nizam al-Mulk was left with wider powers, Malik Shah being only a youth, but by 1080 the sultan had become less acquiescent. Nizam al-Mulk antagonized the sultan's favourite, Taj al-Mulk; he also made an enemy of the sultan's wife Turkan Khatun, preferring a son by another wife for the succession. The great vizier was assassinated on Oct. 14, 1092, while traveling with the court between Isfahan and Baghdad. His murderer was disguised as a Sufi but associated with the Assassins. The view is also held, however, that Taj al-Mulk and Turkan Khatun, if not Malik Shah himself, were privy to the plot.

Nizam al-Mulk in fact failed to achieve the order he had striven for. His hurried but important book on government, the *Siyasat Nama*, composed shortly before he died, proves this. It was a last effort at least to record the theory of a practice he hoped would be established. He did, however, restrain some abuses, and left them condemned, notably in connection with the granting of fiefs to soldiers of the sultan. (P. W. A.)

NIZAMI (JAMALUDDIN or NIZAMUDDIN ABU MOHAMMED ELYAS IBN YUSUF) (*c.* 1135–1203 or perhaps 1217), Persia's leading romantic poet, was born at Ganja (Kirovabad) in the Caucasus, where he spent the whole of his life. Although he enjoyed the patronage of a number of rulers and princes, he was distinguished by reluctance to indulge in extravagant panegyrics, as well as by his simple life and blameless character. Living at a time when Sunni fanaticism was at its height, he was a kindly and tolerant man and his poetry, which is full of reflections on life and people, reveals broad sympathies and deep insight into psychology. His wide learning is shown by his frequent references to historical, literary and scientific topics (he was especially interested in astronomy and music), while his love of nature is seen in his well-observed descriptions and his likable characterizations of animals.

Only a handful of his odes (*qasida*) and lyrics (*ghazal*) have survived; his reputation rests on his great quintet (*Khamsé*) of *mathnavi* (rhymed couplet) poems, totaling some 30,000 couplets. He drew his inspiration from both Firdausi and Sana'i (*qq.v.*) but is himself the first great dramatic poet of Persian literature. His first *mathnavi, Makhzan al-Asrar* (1174–75; English translation by Gholam Hossein Darab, *The Treasury of Mysteries*, 1945) is mystical and philosophical; it was followed by three romantic poems. His last work, possibly completed shortly before his death, was the *Eskandarname* (1200; Eng. trans. of part i by H. W. Clarke, *The Sikander Nama*, 1881), two full-length poems on the life of Alexander the Great.

Nizami is admired in Persian-speaking lands for his originality and his sweetness and clarity of style, though it must be admitted that his love of language for its own sake and of philosophical and scientific learning sometimes led him into obscurity.

BIBLIOGRAPHY.—Nizami's complete works have been edited by Vahid Dastgerdi, 7 vol., 2nd ed. (1954 *et seq.*). *See* also E. G. Browne, *A Literary History of Persia*, vol. ii (1938); E. Berthels in *Encyclopaedia of Islam*, vol. iii (1936). (L. P. E.-S.)

NIZHNI NOVGOROD: *see* GORKI.

NKOLE, an east African people, also known as Banyankole, Ankole or Nyankole, of the Interlacustrine Bantu group who occupy the area between Lakes Edward and George and the Tanganyika border in southwestern Uganda.

The present Nkole kingdom, with a population (1960s) of about 500,000, represents the traditional kingdom of that name with the addition of the neighbouring similar kingdoms of Mpororo, Igara, Buhwezu and Busongora. Together these form a modern administrative district with a common local government headed by the traditional ruler, the *mugabe*.

Although they speak a common language, the Nkole are divided into two quite distinct social groups: the pastoral Hima (Bahima), who constitute about 10% of the population, and the agricultural Iru (Bairu), who make up the remainder. These different economic pursuits give Hima and Iru quite different modes of life. The Hima dwelling is the kraal made up of thatched, beehive-shaped huts arranged in a circle with the intervening spaces filled with branches of thornbush to form a cattle pen. When the grazing in a particular area is exhausted, the kraal, which may house from 12 to more than 100 people, is moved to an area of fresh pasture. The Iru, on the other hand, are sedentary hoe-cultivators of millet, plantains and sweet potatoes who live dispersed in single, though often polygynous, family homesteads surrounded by their gardens and granaries. Both Hima and Iru are divided into patrilineal clans and lineages, though exogamy extends only to children of the same grandparents. Both groups marry with the payment of bridewealth, goats being the medium among the Iru and cattle among the Hima. Hima and Iru are commonly rather different physically—Hima being generally taller, more slender and lighter in colour—and much Nkole traditional history is concerned with explaining how the two groups came to form a single society. Originally, it is said, they lived separately, exchanging their economic products. Then there appeared a wonderful people, the *bacwezi*, who, like the Hima, were tall, light-skinned pastoralists and who conquered the Nkole and their neighbours, establishing a dynasty of kings.

At length the people began to disobey the *bacwezi* and the latter fled the country; however, one, Ruhinda, was persuaded by an Iru headman to remain. Ruhinda thus became the founder of the present dynasty. This legend provided an ideological foundation for the traditional composite society in which Iru lived in politically subordinate but economically symbiotic relationship with Hima. The relationship was further supported by a religious system in which the spirits of the departed *bacwezi* were communicated with by mediums. Marriage between Hima and Iru was prohibited, but Hima sometimes took Iru women as concubines.

Hima were bound to the *mugabe* by clientship—a bond formed by the client's swearing fealty to the *mugabe* and making periodic gifts of cattle to him. From among his clients the *mugabe* chose district chiefs, military captains and the prime minister, the *nganzi*. Often these officials rose in the ruler's service from the royal band of pages formed by boys sent by Hima families to the royal kraal. Iru headmen were appointed over communities of their fellows and through them Hima chiefs collected tribute in agricultural and craft products. *See* also UGANDA; BANTU (INTERLACUSTRINE).

NKRUMAH, KWAME (1909–), dictator of Ghana until 1966 and pan-African statesman, was originally a teacher, trained at Achimota College. He was born at Nkroful on Sept. 18(?), 1909, and he went to the U.S. in 1935, graduating at Lincoln University, in Pennsylvania. He was active in African students' movements in the U.S. and, from 1945, in Britain, where he helped organize the fifth Pan-African Congress and became secretary of the West African National Secretariat. In 1947 he returned home as secretary of the United Gold Coast Convention, with which he broke in 1949, forming the Convention People's Party (CPP) demanding immediate self-government for the Gold Coast. Arrested in 1950, he was released from prison on his election to the Legislative Assembly in 1951. As prime minister from 1952, he led the colony to independence as the new state of Ghana in 1957. In 1960 Ghana became a republic, Nkrumah achieving unrivaled power as life president both of the country and of the CPP, now the sole political party. Nkrumah then concentrated his attention on campaigning for the political unity of Africa, and began to lose touch with realities in Ghana. His increasingly self-seeking administration became involved in magnificent but often ruinous development projects, so that a once prosperous country became crippled with debt. In February 1966, while Nkrumah was visiting Peking, his regime was overthrown by the army and police, Nkrumah himself finding sanctuary in Guinea. He published an autobiography (1957) and a number of expositions of his politics and philosophy. *See* also GHANA: *History*. (J. D. F.)

TOM SMITH FROM CAMERA PRESS

KWAME NKRUMAH

NOAH (in the Douai version of the Bible, NOE) appears in Genesis v, 29 as son of Lamech and tenth in descent from Adam. He is the hero of the story of the Deluge (Gen. vi–viii), being represented as the patriarch who, because of his blameless piety, was chosen by God to perpetuate the human race after his wicked contemporaries had perished in the flood. He receives a divine warning of the impending disaster, and is instructed to build an ark, in which he and his family are preserved alive. In accordance with God's instructions Noah took into the ark specimens of all animals, from which the stocks might be replenished. The story has close affinities with Babylonian traditions, in which Utnapishtim plays the part corresponding to that of Noah.

The narrative of Gen. ix, 18–27 belongs to a different cycle, which seems to know nothing of the flood story. In the latter Noah's sons are married, and their wives accompany them in the ark; but in this narrative they would seem to be unmarried, living in the tent with their father; nor does the shameless drunkenness of Noah accord well with the character of the pious hero of the flood story. Three different motives may be traced in Gen. ix, 18–27: first, the passage explains to whom agriculture, and in particular the culture of the vine, was due; second, it attempts to provide in the persons of Noah's three sons Shem, Ham and Japheth, ancestors for three of the races of mankind, and to account in some degree for their historic relations; third, by its censure of Ham (for whom it is almost certain that Canaan stood in the original text) it reprobates the licentious Canaanite civilization. *See* also GENESIS. (W. L. W.)

NOAHIDE LAWS, a talmudic term denoting seven biblical laws which were given prior to the revelation on Sinai. Addressed to Adam, and in a complete form to Noah, they are considered binding on humanity at large, while Israel, in addition, is to obey the Sinaitic commandments. Using Gen. ii, 16 as the starting point for its exegesis, the Babylonian Talmud (*Sanhedrin* 56–60) considers the Noahide laws to be the prohibition of idol worship and of blaspheming the name of God; the command to establish courts of justice; and the prohibition of murder, adultery and robbery. After the Flood a seventh law was added: the prohibition of eating flesh cut from a living animal (Gen. ix, 4). Some sages added such prohibitions as partaking of the blood drawn from a living animal, castration and sorcery, increasing the number of such laws to 30 (*Hullin* 92a). However, the "seven laws" with minor variations were accepted as the authoritative doctrine. As basic statutes for the safeguarding of monotheism and an ethical order of society, they provided the legal framework for the alien residing in Jewish territory (*Abodah Zarah* 64b). As primarily moral and rational laws, independent of national and denominational limitations, they provided postbiblical Judaism with the concept of universal human rights.

Moses Maimonides regarded a person "who observed the Noahide laws as commanded in the Torah" to be "one of the pious of the Gentiles, assured of a portion in the world to come" (*Mishneh Torah, Hilkhoth Melakhim* VIII, 11). Hugo Grotius recognized the importance of the Noahide concept for the idea of international law; the jurist John Selden noted the relationship between the Noahide laws and modern legislation; the deist writer John Toland saw in them a link between Judaism and Christianity; and the neo-Kantian philosopher Hermann Cohen stressed the moral implication of the concept.

See G. F. Moore, *Judaism in the First Centuries of the Christian Era*, vol. i, *passim* (1946); N. Isaacs, "The Influence of Judaism on Western Law," in E. Bevan and C. Singer (eds.), *The Legacy of Israel*, pp. 383–387 (1927). (N. N. G.)

NOAILLES, a great French family, taking its name from the lordship of Noailles, southeast of Brive, in Limousin (in the modern *département* of Corrèze). Tracing their descent back to the 13th century, members of the family attracted notice in the 16th: ANTOINE (1504–1562), seigneur de Noailles, became admiral of France in 1547 and was ambassador to England from 1553 to 1556; his brother FRANÇOIS (1519–1585), bishop of Dax from 1555, was ambassador to England (1556–57), to Venice (1558) and to Turkey (1572); and a third brother, GILLES (1524–1597), having preceded François in England, was ambassador to Poland and to Turkey before succeeding François as bishop of Dax. Antoine's son HENRI (1554–1623) was created comte d'Ayen in 1593 (Ayen is northwest of Brive). Henri's grandson ANNE (d. 1678), a protégé of Cardinal Mazarin and premier captain of Louis XIV's bodyguard from 1648, was created duc de Noailles and a peer of France in 1663; he also had the governorship of Roussillon, to which his descendants were usually appointed thereafter. His eldest son ANNE JULES (1650–1708), 2nd duc de Noailles, became a marshal of France in 1693 and was viceroy of Catalonia in 1694, during the War of the Grand Alliance. Anne's second son, LOUIS ANTOINE (1651–1729), bishop of Cahors (1679), then of Châlons (1680–95) and ultimately archbishop of Paris (from 1695), is remembered as the long-suffering cardinal de Noailles (from 1700): having approved Pasquier Quesnel's *Réflexions morales*, he was attacked by the Jesuits as pro-Jansenist; and his opposition to Pope Clement XI's bull *Unigenitus* ended ambiguously in 1728, when he accepted it unconditionally after signing a preliminary protest against any such acceptance.

ADRIEN MAURICE (1678–1766), 3rd duc de Noailles, eldest son of the 2nd duc, married Françoise d'Aubigné, niece of Mme de Maintenon, in 1698; fought well in Spain during the War of the Spanish Succession, earning the rank of grandee in 1711; presided over the council of finances from 1715 to 1718 during the regency, but quarreled with the chief minister, Guillaume Dubois; was made a marshal of France in 1734; lost the battle of Dettingen in 1743; and acted as minister of state from 1743 to 1756. His son LOUIS (1713–1793) became duc d'Ayen—a title subsequently borne by the eldest son of each successive duc de Noailles—in 1737; 4th duc de Noailles in 1766; and a marshal of France in 1775. The latter's brother PHILIPPE (1715–1794), duc de Mouchy, also became a marshal in 1775; he and his wife (Anne Louise d'Arpajon, nicknamed Mme Étiquette), having been favourites of the court of Versailles, were both guillotined during the Revolution (June 27, 1794).

JEAN PAUL FRANÇOIS (properly Jean Louis François Paul;

1739–1824), 5th duc de Noailles, did some military service before devoting himself to chemistry, for which he was elected to the Académie des Sciences in 1777: having emigrated during the Revolution, he was received into the reconstituted peerage in 1814. As he had no male issue (his daughter Adrienne was Lafayette's wife), the peerage passed to his grandnephew, PAUL (1802–1885), 6th duc de Noailles, the historian who produced four volumes on the life story of Mme de Maintenon (1848–58) and was elected to the Académie Française in 1849. Paul's grandsons were: ADRIEN MAURICE (1869–1953), 8th duc de Noailles, whose only son and grandson were killed in World War II; HÉLIE, marquis de Noailles (1871–1932), father of the 9th duc; and MATHIEU (1873–1942), whose first wife was the poetess the comtesse de Noailles.

The 1st duc de Mouchy (*see* above) had two sons: PHILIPPE LOUIS (1752–1819), 2nd duc de Mouchy and prince de Poix; and LOUIS MARIE (1756–1804), vicomte de Noailles. The former, deputy to the estates-general, was the sponsor and momentarily the commander of the national guard at Versailles in 1789, emigrated in 1791, returned to support Louis XVI in 1792, re-emigrated, returned to France in 1800 and was received into the reconstituted peerage in 1814. From him descend the later ducs de Mouchy and princes de Poix. The vicomte de Noailles, meanwhile, had served with Lafayette in America before being elected to the estates-general of 1789; he made his name by proposing the abolition of feudal privilege on Aug. 4. Emigrating in 1792, he went to the United States but took part in the French operations of 1803 in Haiti and died of wounds at Havana, Cuba, on Jan. 9, 1804. His son ALEXIS (1783–1835), comte de Noailles, a royalist and an upholder of the papacy against Napoleon (who arrested him for a time in 1809), played some part at the congress of Vienna in 1814 and in French politics from 1815 to 1830; his male line died out in 1926.

NOBEL, ALFRED BERNHARD (1833–1896), Swedish chemist and engineer, who is noted as the founder of the Nobel prizes, was born at Stockholm on Oct. 21, 1833. He spent only two terms in school and thereafter was taught by tutors. About 1850 he was sent on travels to complete his education as an engineer and spent about a year in the United States. He was in ill-health all his life. On his return to Sweden after a stay in St. Petersburg, he studied explosives, especially nitroglycerin. He found that when nitroglycerin was incorporated with an absorbent, inert substance like kieselguhr it could be safely used. In 1867 he was granted a British patent for dynamite and in 1868 a U.S. patent. Nobel next combined nitroglycerin with another high explosive, guncotton, and obtained a transparent, jellylike substance which was a still more powerful explosive than dynamite. Blasting gelatin, as it was called, was patented in 1876. It combined the high power of nitroglycerin with the comparative safety in handling of dynamite. About 13 years later Nobel produced ballistite, one of the earliest of the nitroglycerin smokeless powders and a precursor of cordite. Nobel's claim that his patent covered the latter was the occasion of vigorously contested lawsuits between him and the British government in 1894 and 1895; eventually the courts decided against Nobel. An accomplishment of importance equal to that of his explosives was his construction and perfection of detonators for such explosives as could not be made to explode by simple firing. His detonators contained fulminate of mercury. These detonators made it possible to set off the explosive energy of nitroglycerin, guncotton, etc., at will; without detonators such explosives could not be used at all. From the manufacture of dynamite and other explosives, and from the exploitation of the Baku oil fields, he amassed an immense fortune. He never married. He was lonely and this together with his ill-health imbued him with pessimism and a satirical view of mankind which was nevertheless combined with benevolence and belief in the future of humanity. At his death on Dec. 10, 1896, at San Remo, Italy, he left the bulk of his fortune in trust to establish five prizes in peace, physics, chemistry, physiology or medicine, and literature. *See* NOBEL PRIZES.

(R. E O., X.)

NOBELIUM is the name (with symbol No) that has been suggested for the synthetic chemical element with atomic number 102. In the periodic system of the elements nobelium is the 13th member of the actinide series (*see* PERIODIC LAW; TRANSURANIUM ELEMENTS).

A claim for the first synthesis and identification of this element was made in 1957 by an international team of scientists from the Argonne National Laboratory in the U.S., the Atomic Energy Research Establishment in England, and the Nobel Institute for Physics in Sweden. They suggested the name on the basis of experiments in which they felt they had succeeded in identifying an isotope of element 102 with a half-life of ten minutes, produced from the bombardment of Cm^{244} with C^{13} ions accelerated in the cyclotron at the Nobel Institute. However, subsequent repetition of the experiment in other laboratories failed to confirm the discovery. Credit for the discovery of the element then passed to A. Ghiorso, T. Sikkeland, J. R. Walton, and G. T. Seaborg on the basis of an experiment performed in 1958 at the University of California, Berkeley. Element 102 was produced there on an atom-by-atom basis by the bombardment of Cm^{246} with C^{12} ions accelerated in a heavy-ion linear accelerator. The isotope thus prepared, with mass number 254, was identified through the chemical characteristics of its known "daughter" Fm^{250} the atoms of the daughter element being separated from the parent element 102 by taking advantage of the recoil from alpha-particle decay of the parent element. This isotope of element 102 was subsequently shown to have a half-life of about a minute. A number of isotopes of element 102 were known in the late 1960s as the result of the work of scientists at the University of California and at the Dubna Laboratory in the U.S.S.R.

Isotopes of Element 102

Isotope	Half-life	Type† and energy of radiation (Mev)
102^{251}	~0.7 sec	α8.6
102^{252}	~3 sec.	α8.4
102^{253}	~1.7 min.	α8.0
102^{254}	~1 min.	α8.1
102^{255}	~3 min.	α8.1
102^{256}	~3 sec.	α8.4
102^{257}	~20 sec	α8.3

†α = alpha particle.

The chemical properties of element 102 had not been investigated by the late 1960s, even by the tracer method, due to the short half-lives of all of its known isotopes, and it seemed certain that it would not be possible to work with weighable amounts of the element. It was predicted that the III oxidation state would be found to be the predominant one. The II oxidation state may also be sufficiently stable to exist in solution and in solid compounds.

See G. T. Seaborg, *Man-Made Transuranium Elements* (1963). (G. T. Se.)

NOBEL PRIZES. These prizes, five in number, are awarded annually by four institutions (three Swedish and one Norwegian) from a fund established under the will of Alfred Bernhard Nobel (*q.v.*). Distribution was begun on Dec. 10, 1901, the fifth anniversary of the death of the founder, whose will specified that the awards should annually be made "to those who, during the preceding year, shall have conferred the greatest benefit on mankind" in the fields of physics, chemistry, physiology or medicine, literature and peace.

The institutions mentioned as prize awarders by Alfred Nobel in his will are: the Royal Swedish Academy of Sciences, physics and chemistry; the Royal Caroline Medico-Chirurgical institute, physiology or medicine; the Swedish Academy, literature (all in Stockholm); and the Norwegian Nobel committee, appointed by the Norwegian *storting* (parliament), in Oslo, peace. The Nobel Foundation, established in pursuance with the provisions of the will, is the legal owner and functional administrator of the funds and serves as the joint administrative body of the prize awarders, but it is not concerned with the prize deliberations or decisions, which

1906	Sir Joseph Thomson	(Brit.)	Researches into electrical conductivity of gases	Henri Moissan	(Fr.)	Isolation of fluorine; introduction of Moissan furnace
1907	Albert Michelson	(U.S.)‡	Spectroscopic and metrological investigations using precision optical instruments	Eduard Buchner	(Ger.)	Discovery of noncellular fermentation
1908	Gabriel Lippmann	(Fr.)	Photographic reproduction of colours	Lord Rutherford	(Brit.)	Investigations into the disintegration of elements and the chemistry of radioactive substances
1909	Guglielmo Marconi	(It.)	Development of wireless telegraphy	Wilhelm Ostwald	(Ger.)	Pioneer work on catalysis, chemical equilibrium and reaction velocities
	Karl Braun	(Ger.)				
1910	J. van der Waals	(Neth.)	Research concerning the equation of state of gases and liquids	Otto Wallach	(Ger.)	Pioneer work in alicyclic combinations
1911	Wilhelm Wien	(Ger.)	Discoveries regarding laws governing heat radiation	Marie Curie†	(Fr.)‡	Discovery of radium and polonium; isolation of radium
1912	Nils Gustaf Dalén	(Swed.)	Invention of automatic regulators for lighting coastal beacons and light buoys during darkness or other periods of reduced visibility	Victor Grignard	(Fr.)	Discovery of the so-called Grignard reagents
				Paul Sabatier	(Fr.)	Method of hydrogenating organic compounds in the presence of finely powdered metals
1913	H. Kamerlingh Onnes	(Neth.)	Investigation into the properties of matter at low temperatures; production of liquid helium	Alfred Werner	(Switz.)‡	Work on the linkage of atoms in molecules
1914	Max von Laue	(Ger.)	Discovery of diffraction of X-rays by crystals	Theodore Richards	(U.S.)	Accurate determination of the atomic weights of numerous elements
1915	Sir William Bragg	(Brit.)	Analysis of crystal structure by means of X-rays	Richard Willstätter	(Ger.)	Pioneer researches on plant pigments, especially chlorophyll
	Sir Lawrence Bragg	(Brit.)				
1916	(No award)	...	...	(No award)	...	...
1917	Charles Barkla	(Brit.)	Discovery of characteristic X-radiation of elements	(No award)	...	...
1918	Max Planck	(Ger.)	Discovery of the elemental quanta	Fritz Haber	(Ger.)	Synthesis of ammonia from its elements
1919	Johannes Stark	(Ger.)	Discovery of the Doppler effect in canal rays and of the division of spectral lines in the electric field	(No award)	...	...
1920	Charles Guillaume	(Switz.)	Discovery of anomalies in nickel steel alloys	Walther Nernst	(Ger.)	Work in thermochemistry
1921	Albert Einstein*	(Switz.)‡	Services to theoretical physics, especially the discovery of the law of the photoelectric effect	Frederick Soddy	(Brit.)	Chemistry of radioactive substances; occurrence and nature of isotopes
1922	Niels Bohr	(Den.)	Investigation of atomic structure and radiation	Francis Aston	(Brit.)	Work with mass spectrograph; whole-number rule
1923	Robert Millikan	(U.S.)	Work on elementary electric charge and the photoelectric effect	Fritz Pregl	(Aus.)	Method of microanalysis of organic substances
1924	Karl Siegbahn*	(Swed.)	Discoveries and investigations in X-ray spectroscopy	(No award)	...	...
1925	James Franck*	(Ger.)	Discovery of the laws governing the impact of an electron upon an atom	Richard Zsigmondy	(Aus.)	Elucidation of the heterogeneous nature of colloidal solutions
	Gustav Hertz	(Ger.)				
1926	Jean Baptiste Perrin	(Fr.)	Works on discontinuous structure of matter, especially the discovery of the equilibrium of sedimentation	Theodor Svedberg	(Swed.)	Work on disperse systems
1927	Arthur Holly Compton	(U.S.)	Discovery of wave length change in diffused X-rays	Heinrich Wieland	(Ger.)	Researches into the constitution of bile acids
	Charles Wilson	(Brit.)	Method of making visible the paths of electrically charged particles by vapour condensation			
1928	Sir Owen Richardson	(Brit.)	Discovery of Richardson's law (the dependency of the emission of electrons on temperature)	Adolf Windaus	(Ger.)	Constitution of sterols and their connection with vitamins
1929	Prince Louis de Broglie	(Fr.)	Discovery of the wave nature of electrons	Sir Arthur Harden	(Brit.)	Investigations on the fermentation of sugars and the enzymes acting in this connection
				H. von Euler Chelpin	(Swed.)‡	
1930	Sir C. Raman	(India)	Work on light diffusion; discovery of Raman effect	Hans Fischer	(Ger.)	Hemin, chlorophyll research; synthesis of hemin
1931	(No award)	...	...	Karl Bosch	(Ger.)	Invention and development of chemical high-pressure methods
				Friedrich Bergius	(Ger.)	
1932	Werner Heisenberg	(Ger.)	Creation of quantum mechanics	Irving Langmuir	(U.S.)	Discoveries and investigations in surface chemistry
1933	Paul Dirac	(Brit.)	Discovery of new fruitful forms of atomic energy	(No award)	...	...
	Erwin Schrödinger	(Aus.)				
1934	(No award)			Harold Urey*	(U.S.)	Discovery of heavy hydrogen
1935	Sir James Chadwick	(Brit.)	Discovery of the neutron	Frédéric Joliot	(Fr.)	Synthesis of new radioactive elements
				Irène Joliot-Curie*	(Fr.)	
1936	Victor Hess	(Aus.)	Discovery of cosmic radiation	Peter Debye	(Neth.)	Studies of dipole moments and the diffraction of X rays and electrons in gases
	Carl Anderson	(U.S.)	Discovery of the positron			
1937	Clinton Davisson	(U.S.)	Experimental discovery of the interference phenomenon in crystals irradiated by electrons	Sir Walter Haworth	(Brit.)	Research on carbohydrates and vitamin C
	Sir George Thomson	(Brit.)		Paul Karrer	(Switz.)	Research on carotenoids, flavins and vitamins
1938	Enrico Fermi	(It.)	Disclosure of artificial radioactive elements produced by neutron irradiation	Richard Kuhn	(Ger.)	Carotenoid and vitamin research (declined)§
1939	Ernest Lawrence	(U.S.)	Invention of the cyclotron	Adolf Butenandt	(Ger.)	Work on sexual hormones (declined)§
				Leopold Ruzicka	(Switz.)‡	Work on polymethylenes and higher terpenes
1943‖	Otto Stern	(U.S.)‡	Discovery of the magnetic moment of the proton	George de Hevesy*	(Hung.)	Use of isotopes as tracers in chemical research
1944	Isidor Rabi	(U.S.)‡	Resonance method for registration of magnetic properties of atomic nuclei	Otto Hahn	(Ger.)	Discovery of the fission of heavy nuclei
1945	Wolfgang Pauli	(Aus.)	Discovery of the exclusion ("Pauli") principle	Artturi Virtanen	(Fin.)	Invention of fodder preservation method
1946	Percy Bridgman*	(U.S.)	Discoveries in the domain of high-pressure physics	James Sumner	(U.S.)	Discovery of enzyme crystallization
				John Northrop	(U.S.)	Preparation of enzymes and virus proteins in pure form
				Wendell Stanley	(U.S.)	
1947	Sir Edward Appleton	(Brit.)	Discovery of Appleton layer in upper atmosphere	Sir Robert Robinson	(Brit.)	Investigations on alkaloids and other plant products
1948	Patrick Blackett	(Brit.)	Discoveries in the domain of nuclear physics and cosmic radiation using the Wilson cloud chamber	Arne Tiselius	(Swed.)	Researches on electrophoresis and adsorption analysis, researches on the serum proteins
1949	Hideki Yukawa	(Jap.)	Prediction of the existence of mesons	William Giauque	(U.S.)	Behaviour of substances at extremely low temperatures
1950	Cecil Powell	(Brit.)	Photographic method of studying nuclear processes; discoveries about mesons	Otto Diels	(Ger.)	Discovery and development of diene synthesis
				Kurt Alder	(Ger.)	

Note: Nationality given is the citizenship of recipient at the time award was made.
*Contributor to *Encyclopædia Britannica*. †Awarded two Nobel prizes: physics (1903); chemistry (1911). ‡Naturalized citizen. §Hitler forbade Germans to accept Nobel Prizes (Jan. 1937). ‖No awards made, 1940–42.

TABLE II.—*Nobel Prize Winners (Physiology–Medicine, Literature, Peace), 1901–1950*

Year	Physiology or Medicine			Literature		Peace	
1901	Emil von Behring	(Ger.)	Work on serum therapy	Sully Prudhomme†, poet	(Fr.)	Jean Henri Dunant Frédéric Passy	(Switz.) (Fr.)
1902	Sir Ronald Ross	(Brit.)	Discovery of how malaria enters an organism	Theodor Mommsen; historian	(Ger.)	Élie Ducommun Charles Albert Gobat	(Switz.) (Switz.)
1903	Niels R. Finsen	(Den.)	Treatment of skin diseases with light radiation	B. Bjørnson, novelist, poet, dramatist	(Nor.)	Sir William Cremer	(Brit.)
1904	Ivan Pavlov	(Russ.)	Work on the physiology of digestion	Frédéric Mistral; poet J. Echegaray y Eizaguirre; dramatist	(Fr.) (Sp.)	Institute of International Law	(Founded, 1873)
1905	Robert Koch	(Ger.)	Tuberculosis research	H. Sienkiewicz; novelist	(Pol.)	Baroness von Suttner	(Aus.)
1906	Camillo Golgi S. Ramón y Cajal	(It.) (Sp.)	Work on the structure of the nervous system	Giosue Carducci, poet	(It.)	Theodore Roosevelt	(U.S.)
1907	Alphonse Laveran	(Fr.)	Discovery of the role of protozoa in diseases	Rudyard Kipling, poet, novelist	(Brit.)	Ernesto Teodoro Moneta Louis Renault	(It.) (Fr.)
1908	Paul Ehrlich Elie Metchnikoff	(Ger.) (Russ.)	Work on immunity	Rudolf Eucken; philosopher	(Ger.)	Klas Pontus Arnoldson Fredrik Bajer	(Swed.) (Den.)
1909	Emil Kocher	(Switz.)	Physiology, pathology and surgery of thyroid gland	Selma Lagerlöf, novelist	(Swed.)	Baron d'Estournelles de Constant Auguste Beernaert	(Fr.) (Belg.)
1910	Albrecht Kossel	(Ger.)	Researches in cellular chemistry	Paul von Heyse, poet, novelist, dramatist	(Ger.)	International Peace bureau	(Founded, 1891
1911	Allvar Gullstrand	(Swed.)	Work on dioptrics of the eye	Maurice Maeterlinck; dramatist	(Belg.)	Tobias Asser Alfred Fried	(Neth.) (Aus.)
1912	Alexis Carrel	(Fr.)	Work on vascular suture; transplantation of organs and blood vessels	Gerhart Hauptmann; dramatist	(Ger.)	Elihu Root	(U.S.)
1913	Charles Richet	(Fr.)	Work on anaphylaxis	Sir R. Tagore; poet	(India)	Henri Lafontaine	(Belg.)
1914	Robert Bárány	(Aus.)	Physiology and pathology of vestibular apparatus	(No award)	...	(No award)	...
1915	(No award)	...	...	Romain Rolland; novelist	(Fr.)	(No award)	...
1916	(No award)	...	...	V. von Heidenstam; poet	(Swed.)	(No award)	
1917	(No award)	...	...	Karl Gjellerup; novelist H. Pontoppidan; novelist	(Den.) (Den.)	International Red Cross committee	(Founded, 1863)
1919‡	Jules Bordet	(Belg.)	Discoveries in regard to immunity	Carl Spitteler; poet, novelist	(Switz.)	Woodrow Wilson	U.S.)
1920	August Krogh	(Den.)	Discovery of capillary motor regulating mechanism	Knut Hamsun; novelist	(Nor.)	Léon Bourgeois	(Fr.)
1921	(No award)			Anatole France§, novelist	(Fr.)	Karl Branting Christian Lous Lange	(Swed.) (Nor.)
1922	Archibald V. Hill Otto Meyerhof	(Brit.) (Ger.)	Discovery relating to heat production in muscles Discovery of correlation between oxygen consumption and metabolism of lactic acid in muscles	J. Benavente y Martinez, dramatist	(Sp.)	Fridtjof Nansen	(Nor.)
1923	Sir F. G. Banting J. J. R. Macleod*	(Can.) Brit.)	Discovery of insulin	William Butler Yeats; poet	(Ire.)	(No award)	...
1924	Willem Einthoven	(Neth.)	Discovery of electrocardiogram mechanism	Wladyslaw S. Reymont; novelist	(Pol.)	(No award)	...
1925	(No award)	...	...	George Bernard Shaw; dramatist	(Ire.)	Sir Austen Chamberlain Charles Gates Dawes	(Brit.) (U.S.)
1926	Johannes Fibiger	(Den.)	Discovery of Spiroptera carcinoma	Grazia Deledda; novelist	(It.)	Aristide Briand Gustav Stresemann	(Fr.) (Ger.)
1927	J. Wagner von Jauregg	(Aus.)	Discovery of the therapeutic importance of malaria inoculation in dementia paralytica	Henri Bergson; philosopher	(Fr.)	Ferdinand Buisson Ludwig Quidde	(Fr.) (Ger.)
1928	Charles Nicolle	(Fr.)	Work on typhus	Sigrid Undset, novelist	(Nor.)	(No award)	
1929	Christiaan Eijkman Sir F. Hopkins	(Neth.) (Brit.)	Discovery of antineuritic vitamin Discovery of growth-stimulating vitamins	Thomas Mann, novelist	(Ger.)	Frank B. Kellogg	(U.S.)
1930	Karl Landsteiner	(U.S.)‖	Grouping of human blood	Sinclair Lewis, novelist	(U.S.)	Nathan Söderblom	(Swed.)
1931	Otto Warburg	(Ger.)	Discovery of nature and action of respiratory enzyme	Erik Axel Karlfeldt; poet	(Swed.)	Jane Addams Nicholas Murray Butler	(U.S.) (U.S.)
1932	Edgar D. Adrian* Sir C. Sherrington*	(Brit.) (Brit.)	Discoveries regarding function of the neurons	John Galsworthy; novelist	(Brit.)	(No award)	...
1933	Thomas Hunt Morgan*	(U.S.)	Heredity transmission functions of chromosomes	Ivan Bunin; novelist	(U.S.S.R.)	Sir Norman Angell	(Brit.)
1934	George R. Minot William P. Murphy George H. Whipple	(U.S.) (U.S.) (U.S.)	Discoveries concerning liver therapy against anemia	Luigi Pirandello; dramatist	(It.)	Arthur Henderson	(Brit.)
1935	Hans Spemann	(Ger.)	Organizer effect in embryonic development	(No award)	...	Carl von Ossietzky	(Ger.)
1936	Sir H. H. Dale* Otto Loewi	(Brit.) (Ger.)	Discoveries relating to the chemical transmission of nerve impulses	Eugene O'Neill; dramatist	(U.S.)	Carlos Saavedra Lamas	(Arg.)
1937	Albert Szent Györgyi	(Hung.)	Work on biological combustion	Roger Martin du Gard; novelist	(Fr.)	Viscount Cecil of Chelwood	(Brit.)
1938	Corneille Heymans	(Belg.)	Discovery of role of sinus and aortic mechanisms in respiration regulation	Pearl Buck¶; novelist	(U.S.)	Nansen International Office for Refugees	(Founded, 1931
1939	Gerhard Domagk	(Ger.)	Antibacterial effect of prontosil (declined)♀	Frans Eemil Sillanpää; novelist	(Fin.)	(No award)	...
1943‡	Henrik Dam Edward A. Doisy	(Den.) (U.S.)	Discovery of vitamin K Discovery of chemical nature of vitamin K	(No award)	...	(No award)	...
1944	Joseph Erlanger Herbert S. Gasser*	(U.S.) (U.S.)	Researches on differentiated functions of single nerve fibres	Johannes V. Jensen; novelist	(Den.)	International Red Cross committee	(Founded, 1863)
1945	Sir A. Fleming* Ernst Boris Chain Lord Florey*	(Brit.) (Brit.)‖ (Austr.)	Discovery of penicillin and its curative value in some infectious diseases	Gabriela Mistralδ; poet	(Chile)	Cordell Hull	(U.S.)
1946	Hermann J. Muller*	(U.S.)	Production of mutations by X ray irradiation	Hermann Hesse; novelist	(Switz.)‖	Emily Greene Balch John R. Mott	(U.S.) (U.S.)
1947	Carl F. Cori Gerty T. Cori Bernardo Houssay*	(U.S.)‖ (U.S.)‖ (Arg.)	Discovery of how glycogen is catalytically converted Pituitary hormone function in sugar metabolism	André Gide; novelist, essayist	(Fr.)	American Friends' Service committee Friends' Service council	(U.S.) (London)
1948	Paul Müller	(Switz.)	Properties of DDT	T. S. Eliot; poet, critic	(Brit.)	(No award)	
1949	Walter Rudolf Hess Antonio Egas Moniz	(Switz.) (Port.)	Discovery of function of middle brain Therapeutic value of leucotomy in psychoses	William Faulkner; novelist	(U.S.)	Lord Boyd-Orr	(Brit.)
1950	Philip S. Hench Edward C. Kendall* Tadeusz Reichstein	(U.S.) (U.S.) (Switz.)‖	Research on adrenal cortex hormones, their structure and biological effects	Bertrand Russell; philosopher	(Brit.)	Ralph Bunche	(U.S.)

Note. Nationality given is the citizenship of recipient at the time award was made.
*Contributor to *Encyclopædia Britannica*. †Real name: René François Armand Prudhomme. ‡No awards given in these categories in 1918, 1940–42. §Real name: Anatole François Thibaut. ‖Naturalized citizen. ¶Real name: Pearl (Sydenstricker) Buck Walsh. ♀Hitler forbade Germans to accept Nobel Prizes (Jan. 1937). δReal name Lucila Godoy Alcayaga.

TABLE III.—*Nobel Prize Winners (Physics, Chemistry), 1951–1967*

Year	Physics			Chemistry		
1951	Sir John Cockcroft Ernest Walton	(Brit.) (Ire.)	Work on transmutation of atomic nuclei by artificially accelerated particles	Edwin McMillan* Glenn Seaborg*	(U.S.) (U.S.)	Discovery of and research on transuranium elements
1952	Felix Bloch Edward Purcell	(U.S.)† (U.S.)	Discovery of nuclear magnetic resonance in solids	Archer Martin Richard Synge	(Brit.) (Brit.)	Method of identifying and separating chemical elements by chromatography
1953	Frits Zernike	(Neth.)	Method of phase-contrast microscopy	Hermann Staudinger	(Ger.)	Work on macromolecules
1954	Max Born Walther Bothe	(Brit.)† (Ger.)	Statistical studies on wave functions Invention of and studies with coincidence method	Linus Carl Pauling*‡	(U.S.)	Study of the nature of the chemical bond
1955	Willis Lamb, Jr. Polykarp Kusch*	(U.S.) (U.S.)†	Discoveries concerning the hydrogen spectrum Measurement of magnetic moment of electron	Vincent Du Vigneaud	(U.S.)	First synthesis of a polypeptide hormone
1956	William Shockley John Bardeen Walter Brattain	(U.S.) (U.S.) (U.S.)	Investigations on semiconductors and discovery of the transistor effect	Nikolai Semenov Sir Cyril Hinshelwood	(U.S.S.R.) (Brit.)	Work on the kinetics of chemical reactions
1957	Tsung-Dao Lee Chen Ning Yang	(Chin.) (Chin.)	Discovery of violations of the principle of parity (space reflection symmetry)	Sir Alexander Todd	(Brit.)	Work on nucleotides and nucleotide coenzymes
1958	Pavel Cerenkov Ilya Frank Igor Tamm	(U.S.S.R.) (U.S.S.R.) (U.S.S.R.)	Discovery and interpretation of the Cerenkov effect (emission of light waves by electrically charged particles moving faster than light)	Frederick Sanger	(Brit.)	Determination of the structure of the insulin molecule
1959	Emilio Segrè* Owen Chamberlain	(U.S.)† (U.S.)	Confirmation of the existence of the antiproton	Jaroslav Heyrovsky	(Czech.)	Discovery and development of polarography
1960	Donald Glaser*	(U.S.)	Development of the bubble chamber	Willard Libby*	(U.S.)	Development of radiocarbon dating
1961	Robert Hofstadter Rudolf Mössbauer	(U.S.) (Ger.)	Determination of shape and size of atomic nucleons Discovery of the "Mossbauer effect"	Melvin Calvin	(U.S.)	Study of chemical steps that take place during photosynthesis
1962	Lev D. Landau	(U.S.S.R.)	Contributions to the understanding of condensed states of matter (superfluidity in liquid helium)	John C. Kendrew Max F. Perutz	(Brit.) (Brit.)†	Determination of the structure of hemoproteins
1963	J. Hans D. Jensen Maria Goeppert Mayer* Eugene Paul Wigner	(Ger.) (U.S.)† (U.S.)†	Development of shell model theory of the structure of atomic nuclei Principles governing mechanics and interaction of protons and neutrons in the atomic nucleus	Giulio Natta Karl Ziegler	(It.) (Ger.)	Structure and synthesis of polymers in the field of plastics
1964	Charles H. Townes Nikolai G. Basov Aleksandr M. Prokhorov	(U.S.) (U.S.S.R.) (U.S.S.R.)	Work in quantum electronics leading to construction of instruments based on maser-laser principles.	Dorothy M. C. Hodgkin	(Brit.)	Determining the structure of biochemical compounds essential in combating pernicious anemia
1965	Julian S. Schwinger Richard P. Feynman Shin'ichirō Tomonaga	(U.S.) (U.S.) (Jap.)	Basic principles of quantum electrodynamics	Robert B. Woodward	(U.S.)	Synthesis of sterols, chlorophyll and other substances once thought to be produced only by living things
1966	Alfred Kastler	(Fr.)	Discovery and development of optical methods for studying Hertzian resonances in atoms	Robert S. Mulliken	(U. S.)	Work concerning chemical bonds and the electronic structure of molecules by the molecular orbital method
1967	Hans A. Bethe*	(U.S.)†	Discoveries concerning the energy production of stars	Manfred Eigen Ronald G. W. Norrish George Porter	(Ger.) (Brit.) (Brit.)	Studies of extremely fast chemical reactions

Note: Nationality given is the citizenship of recipient at the time award was made.
*Contributor to *Encyclopædia Britannica*. †Naturalized citizen. ‡Awarded two Nobel prizes: chemistry (1954); peace (1962).

TABLE IV.—*Nobel Prize Winners (Physiology–Medicine, Literature, Peace), 1951–1967*

Year	Physiology or Medicine			Literature		Peace	
1951	Max Theiler	(S.Af.)	Discoveries concerning yellow fever	Par F. Lagerkvist; novelist, poet	(Swed.)	Léon Jouhaux	(Fr.)
1952	Selman A. Waksman	(U.S.)†	Discovery of streptomycin	François Mauriac, poet, novelist, dramatist	(Fr.)	Albert Schweitzer	(Alsatian)
1953	Fritz A. Lipmann Sir H. A. Krebs*	(U.S.)† (Brit.)†	Discovery of coenzyme A Citric acid cycle in metabolism of carbohydrates	Sir Winston Churchill; historian, orator	(Brit.)	George C. Marshall*	(U.S.)
1954	John F. Enders Thomas H. Weller Frederick Robbins	(U.S.) (U.S.) (U.S.)	Cultivation of the poliomyelitis viruses in tissue culture	Ernest Hemingway; novelist	(U.S.)	Office of the United Nations High Commissioner for Refugees	(Founded, 1951)
1955	Axel Hugo Theorell	(Swed.)	Nature and mode of action of oxidation enzymes	Halldór K. Laxness; novelist	(Ice.)	(No award)	...
1956	Werner Forssmann Dickinson Richards* André F. Cournand	(Ger.) (U.S.) (U.S.)†	Discoveries concerning heart catherization and pathological changes in the circulatory system	Juan Ramón Jiménez; poet	(Sp.)	(No award)	...
1957	Daniel Bovet	(It.)†	Production of synthetic curare	Albert Camus; novelist, dramatist	(Fr.)	Lester B. Pearson	(Can.)
1958	George W. Beadle* Edward L. Tatum Joshua Lederberg	(U.S.) (U.S.) (U.S.)	Genetic regulation of chemical processes Genetic recombination; bacterial genetics	Boris Leonidovich Pasternak, novelist, poet (declined award)	(U.S.S.R.)	Dominique Georges Pire, O.P.	(Belg.)
1959	Severo Ochoa Arthur Kornberg	(U.S.)† (U.S.)	Discovery of enzymes for producing nucleic acids artificially	Salvatore Quasimodo; poet	(It.)	Philip J. Noel-Baker	(Brit.)
1960	Sir (Frank) Macfarlane Burnet* Peter B. Medawar	(Austr.) (Brit.)	Discovery of acquired immunity tolerance to tissue transplants	Saint John Perse‡; poet	(Fr.)	Albert J. Luthuli	(S.Af.)
1961	Georg von Békésy	(U.S.)†	Functions of the inner ear	Ivo Andric; novelist	(Yugos.)	Dag Hammarskjöld	(Swed.)
1962	Francis H. C. Crick James D. Watson Maurice Wilkins	(Brit.) (U.S.) (Brit.)	Discoveries concerning the molecular structure of deoxyribonucleic acid	John Steinbeck; novelist	(U.S.)	Linus Carl Pauling*§	(U.S.)
1963	Sir John C. Eccles Alan Lloyd Hodgkin* Andrew F. Huxley	(Austr.) (Brit.) (Brit.)	Study of the transmission of nerve impulses along a nerve fibre	George Seferis‖; poet	(Gr.)	International Red Cross committee League of Red Cross Societies	(Headquarters of both in Geneva)
1964	Konrad Bloch Feodor Lynen	(U.S.)† (Ger.)	Discoveries concerning cholesterol and fatty-acid metabolism	Jean-Paul Sartre; philosopher, dramatist (declined award)	(Fr.)	Martin Luther King	(U.S.)
1965	François Jacob André Lwoff Jacques Monod	(Fr.) (Fr.) (Fr.)	Discoveries concerning regulatory activities of the body cells	Mikhail Sholokhov; novelist	(U.S.S.R.)	United Nations Children's Fund (UNICEF)	(Founded, 1946)
1966	Charles B. Huggins Francis Peyton Rous	(U. S.)† (U. S.)	Research on causes and treatment of cancer	Samuel J. Agnon; novelist Nelly Sachs; poet	(Isr.)† (Swed.)†	(No award)	...
1967	Haldan Keffer Hartline George Wald Ragnar A. Granit	(U.S.) (U.S.) (Swed.)	Discoveries concerning the chemical and physiological visual processes in the eye	Miguel Angel Asturias; novelist	(Guat.)	(No award)	...

Note: Nationality given is the citizenship of recipient at the time award was made.
*Contributor to *Encyclopædia Britannica*. †Naturalized citizen. ‡Real name: Marie René Auguste Alexis Léger. §Awarded two Nobel prizes: chemistry (1954); peace (1962).
‖Real name: Giorgos Stylianou Seferiades.

rest exclusively with the four institutions. Each award consists of a gold medal, a diploma bearing a citation, and a sum of money; the amount depends on the income of the foundation and has ranged from about £11,000 ($30,000) to about £17,000 ($50,000).

The selection of the prize winners starts in the early autumn of the year preceding the awards, with the prize institutions sending out invitations to nominate candidates to those competent under the Nobel statutes to do so. The basis of selection is professional competence and international range; self-nomination automatically disqualifies. Prize proposals must reach the proper committee in writing before Feb. 1 of the year of the prize decision.

On Feb. 1 the Nobel committees start their work on the nominations received. If necessary, the committees may be authorized to call in experts, irrespective of nationality. During September and early October the committees submit recommendations to their respective prize-awarding bodies—only in rare cases has the question been left open. The final decision by the prize awarders must be made by Nov. 15. A committee recommendation is usually but not invariably followed. The deliberation and the voting are secret at all stages. Prizes may be given only to individuals, except the peace prize which may also be given to an institution. Work cannot be proposed posthumously, but a prize duly proposed may be so awarded, as with Dag Hammarskjöld (for peace; 1961) and Erik A. Karlfeldt (for literature; 1931). The awards may not be appealed against. Official support, diplomatic or political, for a certain candidate has no bearing on an award since the prize awarders, as such, are independent of the state.

A prize is either given entire to one person, divided equally between at most two works, or shared jointly by two or more (in practice never more than three) persons. Sometimes a prize is withheld until the following year; if not then awarded it is paid back into the funds, which happens also when a prize is neither awarded nor reserved. Two prizes in the same field can thus be awarded in one year; *i.e.*, the prize withheld from the previous year and the current year's prize. If a prize is declined or not accepted before a set date, the prize money goes back to the funds. Prizes have been declined and in some instances governments have forbidden their nationals to accept Nobel prizes. Those who win a prize are nevertheless entered into the list of Nobel laureates with the remark "declined the prize." The motives given for nonacceptance may vary, but in most instances the reason has been external pressure; *e.g.*, Hitler's decree of 1937 forbade Germans to accept Nobel prizes because the peace prize to Carl von Ossietzky in 1935 was taken as an affront. Whenever possible later, the onetime refuser has explained his situation and on application received the Nobel gold medal and the diploma—but not the money, which has already been paid back into the funds.

Prizes are withheld or not awarded when no worthy candidate in the meaning of Alfred Nobel's will can be found, or when the world situation prevents the gathering of information required to reach a decision, as happened during World Wars I and II.

The Nobel prizes are open to all, irrespective of nationality, race, creed or ideology. They can be awarded more than once to the same recipient. The ceremonial presentations of the prizes for physics, chemistry, physiology or medicine, and literature take place in Stockholm, and that for peace in Oslo, on Dec. 10, the anniversary of Alfred Nobel's death. The laureates usually receive their prizes in person.

The general principles governing awards were laid down by Alfred Nobel in his will. In 1900, supplementary rules of interpretation and administration were agreed upon between the executors, representatives of the prize awarders and the Nobel family, and confirmed by the king in council. These statutory rules have on the whole remained unchanged, but have been somewhat modified in application; *e.g.*, the ambiguous words in the will, "idealistic tendency" as qualification for the prize for literature, were in the beginning interpreted verbally, but have gradually been interpreted more flexibly, as the list of laureates shows.

The scientific and medical prizes have proved to be the least controversial, while those for literature and peace by their very nature have been the most exposed to critical differences. The peace prize has been most frequently reserved.

NOBILE, UMBERTO (1885–), Italian aeronautical engineer and explorer, a pioneer of arctic aviation, was born at Lauro, Avellino, on Jan. 24, 1885. Trained as an engineer in Naples, he did much pioneer work for Italy during and after World War I in the field of aircraft construction. In 1926, together with Roald Amundsen and Lincoln Ellsworth, he flew in his semirigid airship the "Norge" over the north pole from Spitsbergen to Alaska. Nobile was promoted to general in the Italian air force and appointed professor of aeronautical engineering at the University of Naples. Although the type was criticized as being too small and delicate for use in the polar regions, it was with an almost identical airship, the "Italia," that Nobile undertook in 1928 a new series of flights over unexplored areas of the arctic. On the third flight the airship crashed on the ice north-northeast of Spitsbergen. A vast international rescue operation was launched; Nobile and seven of his companions were eventually rescued, but the catastrophe cost, directly or indirectly, 17 lives. Nobile's conduct was the subject of fierce controversy and an Italian commission of inquiry, in all probability partial, found him responsible for the disaster, whereupon he resigned his rank. In 1931 he took part in the arctic voyage of the Soviet vessel "Malygin," and from 1932 to 1936 he was concerned with the construction of dirigibles in the Soviet Union. He was reinstated in 1945 and resumed his teaching post at Naples. In 1946 he was a Communist deputy in the Italian constituent assembly.

Nobile published numerous works, both on aeronautics and his polar experiences, including *Posso dire la verità* (1945), a final statement of his view of the "Italia" tragedy. (P. A. B. G.)

NOBLE, SIR ANDREW, 1ST BART. (1831–1915), British physicist and artillerist whose classical researches with Sir Frederick Abel on fired gunpowder contributed greatly to the progress of gunnery, was born at Greenock, Renfrewshire, Scot., Sept. 13, 1831. Educated at Edinburgh academy and the Royal Military academy, Woolwich, London, he entered the royal artillery in 1849 and, as secretary of the select committee on smoothbore and rifled cannon, he devised an ingenious method of comparing the accuracy of fire of each type of gun. He became assistant inspector of artillery (1859), then served on the ordnance select committee and the explosives committee, but left the service to join the firm of Sir William (later Lord) Armstrong (*q.v.*) of which he became chairman in 1900. About 1862 he applied his chronoscope, a device for measuring very small time intervals, to determine the velocity of shot in gun barrels with different powders and charges. He was an advocate of nitro (smokeless) powders. Noble was elected a fellow of the Royal society (1870), awarded a royal medal of the society (1880) and created a baronet (1902). He died in Argyll, Scot., on Oct. 22, 1915. His papers were collected as *Artillery and Explosives* (1906). (D. McK.)

NOBRE, ANTÓNIO (1867–1903), Portuguese poet, whose *Só* ("Alone")—the only volume of his verse published during his lifetime—gives an intensely personal expression to the deep vein of melancholy in the national character, was born in Oporto on Aug. 16, 1867, the son of a well-to-do middle-class family. He studied law unsuccessfully for two years at Coimbra university and then, during 1890–95, attended the École Libre des Sciences Politiques in Paris. Having been a consumptive, Nobre spent the remaining years in travel. In Paris, where his memories of a childhood spent in the company of peasants and sailors of northern Portugal contrasted sharply with his impressions of the cosmopolitan drabness of the Left Bank, he wrote the greater part of the *Só* (1892; final version, 1898), in which he succeeded in blending the traditional trend of a genuine and simple lyricism with the more refined and subtle perceptiveness of the French Symbolists. This line of literary development evolves clearly from his early compositions, *Primeiros Versos* (1921), to the valedictory garland of *Despedidas* (1902).

The *Só* met with a mixed reception, but became one of the mo...

popular works of poetry in Portugal. Its originality springs partly from the creation of a personal mythology applied to significant place-names of a sentimental itinerary; a quasi-Franciscan acceptance of death adds the uneasy note of a subdued protest against the transiency of the world. Nobre's rejection of reality and his narcissism, however, engender a cloying sense of frustration. His vision of Portugal partakes of the bucolic enchantment that it describes in the fluent vein of a nursery tale. Herein lies its strength and its major weakness. Nobre died at Foz do Douro on March 18, 1903.

Gaspar Simões, vol. ii, pp. 457–477 (1948); Guilherme de Castilho, *António Nobre* (1950). (L. DE S. R.)

NÓBREGA, MANUEL DA (1517–1570), was the Portuguese founder of the Jesuit mission of Brazil. In Bahia, where he arrived from Lisbon in 1549, he founded the first Jesuit college in the new world. He was the first provincial of the Brazilian province of the Society of Jesus (1553–59). He was again named provincial in 1570 but died in Rio de Janeiro before the news of the appointment reached him. Nóbrega was instrumental in establishing the Jesuit college around which São Paulo grew (1554) and is therefore known as the founder of Brazil's largest city. When the French under Nicolas de Villegagnon, including many Huguenots, settled in Rio (1555), Nóbrega moved heaven and earth against them. They were expelled in part because he won over to the Portuguese side the Tamóio Indians (1563).

"There is no individual," Robert Southey wrote, "to whose talents Brazil is so greatly and permanently indebted. . . ." In many ways because of Nóbrega, southern Brazil was destined to remain Catholic and Portuguese. *See* also BRAZIL: *History*. (M. CA.)

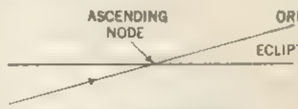
NOCERA INFERIORE (formerly NOCERA DEI PAGANI; ancient NUCERIA ALFATERNA), a town in Salerno province, Campania region, southern Italy, situated at the foot of Montalbino, 23 mi. E.S.E. of Naples, 135 ft. above sea level. Pop. (1961) 42,924 (commune). The origin of the epithet *dei Pagani* ("of the pagans") is not historically established and is sometimes attributed to Pagum village or to Pagano, the name of an important local medieval family. Nuceria Alfaterna, sacked by Hannibal in 216 B.C., was rebuilt by Augustus. In the old castle, Helen, widow of King Manfred of Sicily, died in captivity (1271) five years after the battle of Benevento. The city early became an episcopal see and in the 12th century it sided with Innocent II against Roger of Sicily suffering for its choice the destruction of its walled centre. In the nearby village of Nocera Superiore is the circular domed church of Sta. Maria Maggiore (dating from the 4th century). Other ancient ecclesiastical buildings include S. Antonio's (13th century, with an altar piece by Andrea da Salerno), Sta. Anna's monastery (with frescoes by Francesco Solimena), S. Andrea's convent (14th century) and S. Giovanni's convent (dating from the 11th century). Nocera Inferiore now ranks first economically in the province because of its agricultural exports, its well-established lumber mills, canning, macaroni and textile plants.

(LU. L.; AL. M.; SA. P.)

NOCTURNE, the name, principally found in the 19th century, of a form of music. It originated from the Italian *notturno*, an 18th-century form of music associated with, or to be played during, the night, as opposed to *serenata*, an evening piece. *Notturnos* for various combinations of instruments and in several movements were written by Haydn, Adalbert Gyrowetz and Mozart, whose *Eine Kleine Nachtmusik* also comes under this heading. The French form, *nocturne*, was first used in 1814 by John Field as the title of pieces for the piano in different styles, and later by Chopin who established the romantic or introspective character of the nocturne. A similar conception is seen in the nocturnes for piano by Gabriel Fauré. The term was also used by Mendelssohn for an interlude in his *Midsummer Night's Dream* music, and by Debussy as the title of three pieces for orchestra. The German form of the word, *Nachtstück*, was used for pieces by Schumann and Paul Hindemith.

NODDY, the name applied to seabirds of the genus *Anous*, of the tern (*q.v.*) subfamily, and especially to *A. stolidus*, showing so little fear of man as to be judged stupid. It is heavier in flight than most terns, with shorter wings and less forked tail. The plumage is of a uniform sooty hue, except the light gray crown of the head. The noddy is generally distributed throughout tropical and subtropical oceans. It breeds in astounding numbers, on low cays and coral islets, making a nest composed of seaweed or small twigs. Other birds of the same genus are the darker Pacific noddy (*A. s. sidgwayi*), the still darker Galapagos noddy (*A. s. galapagoensis*) and the white-headed noddy (*A. leucocapillus*).

NODE (from the Lat. *nodus*, "loop"), in astronomy, the intersection of the ecliptic (the apparent path of the sun among the stars) with the path of the moon or of a planet projected on the celestial sphere. The ascending node is the one where the body crosses from the south to the north side of the ecliptic, the opposite one being the descending node. An eclipse or transit of a planet has to occur when the moon or planet is at or near a node, for that is the only time that the sun, moon or planet and earth can be lined up suitably.



ASCENDING NODE

In the geometry of curves, a node is the name given to the loop formed by a continuous curve crossing itself. The point of crossing is termed a "double point," and at it there are two noncoincident tangents to the curve; the remaining species of double points—termed acnode, spinode or cusp—admits of two coincident tangents. *See* also CURVES. (H. M. LO.)

NODIER, CHARLES (1780–1844), French writer, an early master of the fantastic story, was born on April 29, 1780, at Besançon, and educated there. The political agitation of the time and his experience of the Terror made a deep impression on him; he escaped from reality into a world of fantasies fed by his omnivorous reading and his passion for natural history. The turmoil of these early years ended with his marriage to Désirée Charve in 1808; this was followed by periods of employment as secretary and librarian, and of writing and travel. In 1824 he was appointed curator of the library at the Arsenal. He died in Paris on Jan. 27, 1844.

Nodier is generally remembered for such stories as his *Histoire du Chien de Brisquet* (1830), *Le Songe d'or* (1832), *Jean François les Bas-Bleus* (1832) and *Trésor des fèves et fleur des pois* (1833), written in a prose always classically pure but with a simplicity that sometimes seems a little childish; and also for the literary *salon* in his rooms at the Arsenal, where from 1824 to 1830 he gathered round him the principal representatives of the newly formed romantic school. It is unjust, however, to recall only these two aspects of his many-sided career. He had an encyclopedic mind and studied a wide range of subjects—botany, entomology, linguistics, bibliography—in each of which he displayed extensive, though not always infallible, erudition. He wrote in many different literary kinds, publishing poems, critical studies, philosophical essays, books of travel, reminiscences of his youth, novels (*Jean Sbogar*, 1818; *Mademoiselle de Marsan*, 1829) and a fantasy which eludes classification (*Histoire du roi de Bohème et de ses sept châteaux*, 1830).

But it is his stories which remain outstanding, though the best are not those constantly anthologized for children. Nodier's originality was to find in the world of dreams an untapped source of literary inspiration. *Smarra ou les démons de la nuit* (1821) is a prose poem of nightmare; *Trilby* (1822), another prose poem, is a reverie of love; *La Fée aux miettes* (1832) describes the delusions of a "lunatic" in its root meaning of one made mad by the moon. By this revelation of the creative power of dream and by his equation of a state of innocence with certain conditions normally called mad, Nodier was rebelling against the tyranny of "common sense" (*le bon sens*) and opening up a new territory to literature. Gerard de Nerval, Lautréamont (*qq.v.*) and the surrealists explored the same realm and hailed him as a precursor of their own fantasies.

NŌ DRAMA. Toward the end of the 14th century a father and son, Kan-ami and Zeami (*see* ZEAMI MOTOKIYO), by making innovations and refinements in *sarugaku-nō*—an entertainment derived from ancient native and foreign sources—created the nō theatre of Japan, which survives in modern times in much the same form as that in which it was conceived. Kan-ami's troupe, previously associated with a Shintō shrine, was taken under the patronage of the temporal ruler, the shogun Yoshimitsu. Thereafter and well into the 19th century the nō was a fashionable amusement of the aristocracy and the warrior class but certain performances, called subscription nō, were open to and popular with commoners. The nō thus greatly influenced the subsequent dramatic expression of the commoners, the puppet theatre and the kabuki, which appeared at the end of the 16th century.

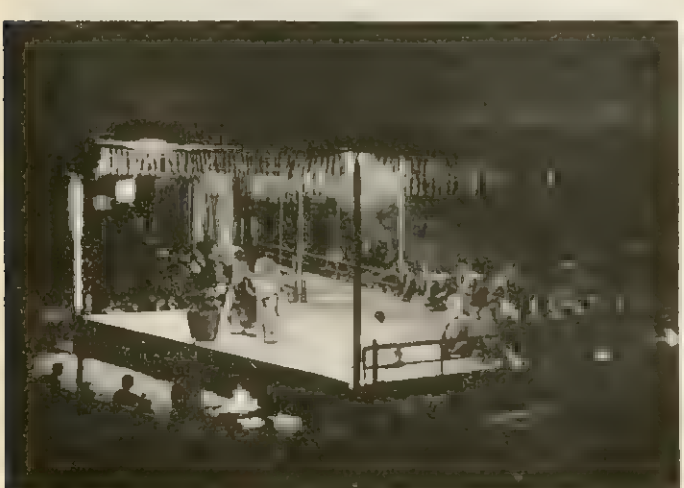
The nō is nonrealistic. The actors, all male, are singers and dancers. They wear theatrical versions of 14th-century costumes and in some roles are masked. The rhythmical basis of the performance is provided by two or three drummers and a flutist. A chorus of six or more men chants the narrative parts of the play and sometimes the words of the characters.

Classification of Nō Plays.—Out of more than 2,000 plays, about 240—the majority of which were written during the 15th century—constitute the modern repertoire. These are divided into five principal groups: (1) congratulatory pieces praising the prosperity of the country; (2) plays about warriors, as men and as ghosts; (3) those which usually have an elegant, beautiful woman as leading character; (4) plays (the largest group, containing various types) dealing with insanity, obsession and historical characters; (5) pieces concerning demons and gods. The traditional, daylong performance consisted of a play from each of the groups, in the above order, with comic interludes in colloquial language (*kyōgen*) played between them; after 1945 the usual program consisted of two or three plays with comic interludes.

Construction of Nō Plays.—Nō plays are written in poetic form, using a variety of complex, untranslatable literary devices. Usually there are only two important roles: the *shite* or principal character and the *waki* or secondary one. Considered apart from the Japanese classification, the plays are of two types: those set entirely in the "real" world, and those in which an apparition or supernatural being appears. The majority of the plays and those most frequently performed belong to the latter group. These vary in detail but the general form is this: The *waki,* often a priest or monk, enters first; he is joined by the *shite* at a place of historical or religious significance. The *shite,* though appearing to be an ordinary person, reveals unusual knowledge of the spot. The *shite* then exits. During a short interlude he changes costume and mask and reappears for the second part in his true form. He is described in his first appearance as the "before"-*shite,* in his second as the "after"-*shite;* there is often a complete contrast between the two, so that they are entirely different roles. The *shite* may first be a beautiful girl, then a serpent; an old village woman, then a demon; a boy, then the spirit of a warrior. On his second appearance the *shite,* with the help of the chorus, gives an account of his essential being, climaxed by his principal dance. A hunter dances his killing of birds in life and the punishment he later suffers in hell for this sin. The woman who in life had an illicit passion for a priest reveals her true nature by wearing the mask of a demon and a costume of stylized pattern suggesting the scales of a snake. The great warrior relives his last battle. All such characters are chained to their earthly passions, which bind them to the world of actuality and prevent their attainment of nirvana. They appeal to the priest or monk to pray for the repose of their spirits. Because the priest possesses knowledge of the likeness of all living things he receives requests for deliverance and enlightenment not only from the spirits of human beings, but also from the snow, a butterfly or the wisteria.

AUTHENTICATED NEWS INTERNATIONAL

NŌ ACTOR: CHORUS AND MEMBER OF THE ORCHESTRA IN BACKGROUND



BY COURTESY OF THE CONSULATE GENERAL OF JAPAN

"TAKIGI NŌ," TRADITIONALLY PLAYED IN THE LIGHT OF A BONFIRE AT NIGHT

Staging.—The stage has two principal areas: the stage proper about 18 ft. square; and the bridge (*hashigakari*), about 6 ft. wide and between 33 and 52 ft. long, which connects the dressing room with the stage proper and is used for entrances and exits by the principal characters. Lesser characters and musicians use a low door in the upstage corner of the stage. The chorus occupies an area to the left of the actors; the instrumentalists sit at the rear of the stage. Both playing areas are roofed, as they were in the earliest outdoor theatres, although most nō stages are now constructed within a building. The out-of-doors is also recalled in the stylized pine tree painted on the rear wall of the stage, the painted bamboo design on the narrow wall to the side of it, the strip of white pebbles between the playing areas and the auditorium and the three small pine trees in front of the bridge. The pillars supporting the roof have conventional spatial values and determine the pattern of the actor's movement. Scenic objects, rarely used, do not often resemble literal objects, but merely suggest them. Many properties are similarly sketchlike; the most frequently used is the folding fan, which—closed, partially closed or open—conveys any meaning suggested by its form or manipulation.

NOEL-BAKER, PHILIP JOHN (1889–), British statesman and internationalist who advocated international disarmament in the cause of world peace and who was awarded the Nobel peace prize in 1959. Born in London, Nov. 1, 1889, of a Quaker family, he was educated at Bootham school, York; Haver-

ford college, Pennsylvania, and at King's college, Cambridge. President of the Cambridge Union society in 1912, he also captained the 1924 British Olympic Games team. During World War I he served with the Friends' and other ambulance units in France, Belgium and Italy, being decorated for distinguished conduct. After working at the peace conference in 1919 as a member of the British delegation, he joined the secretariat of the League of Nations. He assisted Fridtjof Nansen in his work for refugees, Lord Robert Cecil at sessions of the assembly and Arthur Henderson, the president, at the world disarmament conference at Geneva, 1932–33.

In the house of commons Noel-Baker represented Coventry (1929–31), Derby (1936–50) and South Derby after Feb. 1950, as a Labour member. Between 1945 and 1951 he was successively minister of state, secretary of state for air, secretary of state for Commonwealth relations and minister of fuel and power. Aided by a fluent command of seven languages, he campaigned for 40 years for peace through international disarmament. *The Arms Race: a Programme for World Disarmament* (1958) was acclaimed as a monumental survey of the whole disarmament problem. (L. R. A.)

NOETHER, (AMALIE) EMMY (1882–1935), German mathematician who specialized in higher algebra, was born at Erlangen on March 23, 1882. Her father Max Noether (1844–1921) was a distinguished mathematician; a younger brother, Fritz Noether, became professor of applied mathematics. She studied in Erlangen, later in Göttingen, where she passed her habilitation examination in 1919, after earlier objections from some members of the faculty opposed to woman lecturers.

In 1922 she became extraordinary professor in Göttingen, a position she held until 1933, when she left Germany to accept a professorship at Bryn Mawr college, Pennsylvania. She died on April 14, 1935.

Emmy Noether's studies on abstract rings and ideal theory have been of importance for the development of modern algebra; she also exerted great scientific influence through her many able pupils. (O. OE.)

NOGALES, a desert town in the Mexican state of Sonora, contiguous with and across the border from Nogales, Ariz., U.S., and port of entry into Mexico. Pop. (1960) 37,657. The Pacific highway leading to Mexico City (1,500 mi.) via Hermosillo, Guaymas, Mazatlán and Guadalajara begins at this point. A rail line follows the same route. Nogales is noted for its cavern restaurant, a cafe in a cave which was once used as a jail under Chureas hill. Nogales is a U.S.-Mexican trading centre in cattle and minerals. Irrigation of large areas of the state brought increased wealth to Nogales, but the main farm areas are to the south. (J. A. Cw.)

NOGARET, GUILLAUME DE (d. 1313), French magistrate, one of the most vigorous of the *légistes* or expositors of the royal power, especially in ecclesiastical affairs, was born between 1260 and 1270 at St. Félix-de-Caraman, the son of a bourgeois of Toulouse; his family, which was later accused by his enemies of having adhered to the heresy of the Cathari, held a small property at Nogaret nearby. He began his career as a teacher of jurisprudence at Montpellier in 1291, entered the royal service as *juge-mage* at Nîmes about 1294 and seems to have been with King Philip IV (*q.v.*) in Normandy in 1295. A member of the king's council, he was entrusted in 1296 with missions to Bigorre and to Champagne for the enforcement of the king's rights there. In 1299 he began to style himself *miles*, or knight.

Nogaret is chiefly remembered for his role in Philip IV's conflict with Pope Boniface VIII (*q.v.*). Little is known of his mission to Rome in 1300. On March 7, 1303, however, Philip authorized him to go to Italy to take measures against the pope; and five days later, on March 12, at a meeting in Paris, it was Nogaret who, after denouncing the pope (1) as irregularly installed, (2) as a heretic, (3) as a simonist and (4) as a notorious sinner, demanded the summoning of a general council of the church to try him. Proceeding to Italy, he established himself at Staggia in Tuscany, whence he made contact with the pope's enemies, including some cardinals. The pope, meanwhile, was spending the summer at Anagni, southeast of Rome; and there was a quarrel between Anagni and the neighbouring town of Ferentino. At dawn on Sept. 7, 1303, Nogaret and Rinaldo di Supino, captain of Ferentino, entered Anagni with a small force to arrest the pope (who was intending next day to issue his bull *Super Petri solio*, excommunicating Philip); but Sciarra Colonna, whose family was pursuing its own vendetta against Boniface, entered Anagni with his men at the same time, and the pope fell into their hands. Nogaret saved the pope's life, but the violence of the Colonna faction not only frustrated his carefully prepared show of legality but provoked the people of Anagni, who had at first connived at the coup, to rise on Sept. 9 in defense of the pope. Forced to abandon his enterprise and to flee to Ferentino, Nogaret returned to France early in 1304.

Nogaret had acted as a sincere Christian desirous of freeing the church from a pope whom he thought unworthy; but Boniface's successor Benedict XI, though he exculpated Philip, issued the bull *Flagitiosum scelus* (June 7, 1304), excommunicating Nogaret and 15 other participants in the outrage. Philip, however, raised Nogaret's pension from 300 to 800 livres and, on Sept. 22, 1307, appointed him keeper of the great seal.

Nogaret was from 1307 much occupied with the conduct of Philip's proceedings against the Templars (*q.v.*). After long appealing against his excommunication, he obtained absolution from Pope Clement V on April 27, 1311, with the proviso that he should go as a pilgrim to the Holy Land at the first opportunity and stay there until the pope should recall him. He died, however, before executing this proviso, in April 1313. His influence has been exaggerated, and it is a mistake to see his hand in all the state trials of Philip IV's reign.

See R. Holtzmann, *Wilhelm von Nogaret* (1898); R. Fawtier, "L'Attentat d'Anagni," *Mélanges d'archéologie et d'histoire*, lx (1948). (F. CT.; X.)

NOGINSK, a town of Moscow *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on the Klyazma river, 54 km. (34 mi.) E. of Moscow city. Pop. (1959) 92,760. It developed in the 15th–16th centuries as Yamskaya settlement, and was known later as Rogozhi and, from 1781 (when it became a town) to 1930, as Bogorodsk. In the 19th century the textile industry developed there and it is now one of the most important textile centres of the U.S.S.R. Cottons form over three-quarters of its production, but wool and silk goods are also made. Other products include parts for tractor engines, needles and reinforced concrete. A branch railway joins Noginsk to the Moscow-Gorki line. (R. A. F.)

NOGUCHI, HIDEYO (1876–1928), Japanese bacteriologist, was born in Inawashiro, Fukushima, Japan, Nov. 24, 1876. He graduated from Tokyo Medical college in 1897 and two years later emigrated to Philadelphia. At the University of Pennsylvania he assisted Weir Mitchell in his studies on snake venoms. In 1904 Noguchi went to the Rockefeller Institute for Medical Research in New York city, where he worked the rest of his life. He was the first to demonstrate spirochetes of syphilis in the central nervous system of patients dying of paresis and tabes dorsalis, thereby proving the syphilitic origin of those diseases. He improved the technique and theory of the Wassermann reaction.

Adapting a method first employed by Theobald Smith, Noguchi devised ingenious means of cultivating microorganisms that had never before been grown in the test tube. He discovered a number of new microorganisms which he erroneously described as causes of infectious diseases now known to be caused by viruses; *e.g.*, poliomyelitis, trachoma and yellow fever. He succeeded in growing spirochetes which he believed to be those that cause syphilis.

During his lifetime, Noguchi was regarded as one of the world's greatest bacteriologists, but of his later "discoveries" only a few —*e.g.*, the cultivation of the parasite of Oroya fever (Carrión's disease) and verruga peruana, which he showed to be different manifestations of the same infection—have stood the test of time. He was a dedicated and indefatigable scientist, and no one who knew him could doubt the sincerity of his own belief in the validity of his claims. When he learned that other bacteriologists had

announced that yellow fever was caused by a virus, Noguchi went to British West Africa to join them, in order to resume his study of that disease. While doing so, he contracted yellow fever and died in Accra on May 21, 1928. (C. P. M.)

NOGUCHI, ISAMU (1904–), U.S. sculptor of Japanese descent, one of the strongest advocates of the expressive power of abstract shapes, was born at Los Angeles, Calif., on Nov. 7, 1904. To his terra-cotta and stone sculptures Noguchi brought some of the spirit and mystery of early art, principally Japanese earthenware, studied during residences in Japan. Trained as a premedical student at Columbia university, Noguchi sensed the interrelatedness of bone and rock forms, the comparative anatomy of existence, as seen in his "Kuros" (1945). Recognizing the appropriateness of sculptural shapes for architecture, he made many important contributions toward the aesthetic reshaping of physical environment. His garden for UNESCO in Paris (1958), his playground, lamp, chair and table designs have won international praise. He also designed a monument to the dead and a bridge for Hiroshima, but only the latter was actually built.

See C. Giedion-Welcker, ***Contemporary Sculpture*** (1955).
(A. E. EL.)

NOIR, VICTOR (properly YVAN SALMON) (1848–1870), French journalist whose death brought sensational discredit on the reigning dynasty in the last year of the second empire, was born at Attigny (Vosges) on July 27, 1848. With only a rudimentary education, he worked first as a watch repairer in his father's shop and later as a florist before joining *L'Époque*, a Paris newspaper, as a gossip writer. He subsequently wrote for many other journals, the last being the republican *Marseillaise*. On Jan. 10, 1870, he presented himself with a colleague, Ulric de Fonvieille, at the house of Prince Pierre Napoléon Bonaparte, a first cousin of the emperor Napoleon III, to deliver a challenge to a duel from another journalist, Paschal Grousset. An altercation ensued, during which the prince drew his revolver and killed Noir. Noir's funeral, on Jan. 12, became a riotous republican manifestation. The emperor ordered an inquiry. Tried by a special high court of justice at Tours, the prince was acquitted on March 25 on his statement that Noir had provoked him by slapping his face—an allegation which had been denied by Fonvieille.

NOISE AND ITS CONTROL. In acoustics noise is defined as any undesired sound. According to this definition, the sound of church bells may be music to some and noise to others. Usually, noise is a mixture of many tones combined in a nonmusical manner.

Measurement and Specification.—The measurement of any sound stimulus is commonly made with a sound-level meter and a frequency analyzer (*see* SOUND). The sound-level meter comprises a microphone and associated electronic equipment. The analyzer is an electronic device for separating the noise into its tonal components, or into groups of tonal components. The results of a measurement are given in decibels (db), which is called the sound-pressure level and is equal to 20 times the logarithm of the ratio of the sound pressure in the air to a reference sound pressure (usually 0.0002 dyne per square centimetre). For example, a sound pressure of one dyne per square centimetre has a sound-pressure level of 74 db. The decibel is to sound what the degree is to temperature. It indicates the magnitude of the sound, but not the reaction of human beings to it. Typical sound levels in decibels, considering all audible tonal components contained in the sound are shown in Table I. Outdoors, the sound levels decrease six decibels each time the distance between the source and the microphone is doubled. Conversely, the sound increases six decibels each time the distance is halved. Indoors, the acoustics of the room greatly modify this rule.

The intensity of a sound source may be indicated by the total power in watts that it produces in the air around it. Acoustic powers of common sound sources are shown in Table II. The total range is nearly 100,000,000,000,000 times the Table minimum.

Sounds may be divided into three classes: (1) those that are composed of one or more pure tones, such as a note from the piccolo: (2) those that contain a great many very closely spaced tones,

TABLE I.—*Typical Overall Sound Levels*
(As measured on an American standard sound-level meter)

At a given distance from noise source	Decibels* re 0.0002 microbar	Environmental
50-h.p. Victory siren (100 ft.)	-140 dbc-	
F-84 at takeoff (80 ft. from tail)		
Hydraulic press (3 ft.)	-130 dbc-	
Large pneumatic riveter (4 ft.)		Boiler shop (maximum level)
Pneumatic chipper (5 ft.)	-120 dbc-	
Multiple sand blast unit (4 ft.)		Engine room of submarine (full speed)
Trumpet auto horn (3 ft.)		
Automatic punch press (3 ft.)		Jet engine test room
	-110 dbc-	
Chipping hammer (3 ft.)		Woodworking shop
Cut-off saw (2 ft.)		Inside four-engine piston airliner
Annealing furnace (4 ft.)		Weaving room
	-100 dbc-	
Automatic lathe (3 ft.)		Can manufacturing plant
Subway train (20 ft.)		Inside Chicago subway car
Heavy truck (20 ft.)		
Train whistle (500 ft.)		Inside motorbus
	- 90 dbc-	
Small truck accelerating (30 ft.)		Inside sedan in city traffic
	- 80 dbb-	
Light truck in city (20 ft.)		Office with tabulating machines
Auto (20 ft.)		Heavy traffic (25 to 50 ft.)
	- 70 dbb-	
		Average traffic (100 ft.)
		Accounting office
Conversational speech (3 ft.)		Chicago industrial areas
	- 60 dbb-	
Transformer (200 ft.) (15,000 kva., 115 kv.)		
	- 50 dba-	Private business office (noisy)
		Light traffic (100 ft.)
		Average residence
	- 40 dba-	
		Private business office (quiet)
		Minimum levels for residential areas in Chicago at night
	- 30 dba-	Broadcasting studio (speech)
		Broadcasting studio (music)
	- 20 dba-	Studio for sound pictures
	- 10 dba-	
Threshold of hearing—young men	- 0 dba-	

*The suffixes attached to db, (dba, dbb and dbc) indicate the manner in which the sound-level meter was operated; *e.g.*, when the scale of the meter is set to "c," the meter ... the sound-pressure level as defined in the text. When set to "a" or "b" the meter ... into account, partially, the manner in which a human listener judges the loudness ... weaker sounds.

such as the noise of a waterfall or of a jet aircraft engine; (3) combinations of the first two, such as a whistle in a busy factory.

Effects on Man.—Noise may have a number of effects on man: it may annoy him or it can disturb his sleep; it can interfere with his ability to converse with someone else; it can damage his hearing. The operators of airports near large cities have learned that complaints about noise are related to the power and type of aircraft, the distance from the airport to the residents and the frequency of passage of the aircraft. Similar experiences for other types of noise are becoming available from factory owners and city p...

ners. Those tonal components of a noise that lie between 300 and 5,000 cycles per second interfere most with conversation (*see* HEARING).

Sudden damage to hearing may result from the noise of a blast or an explosion. Gradual damage may result from continued exposure to noise over a period of years. Other factors being equal, a steady sound (such as that of a textile mill) will be less likely to damage hearing than one that is impulsive (as that of a pneumatic hammer or a drop forge). People vary considerably in their susceptibility to such damage. Many companies periodically test the hearing of workers in noisy areas and transfer those who show signs of deafness. Those who work around jet aircraft, in boiler shops, in drop-forge shops or those who use metal-cutting, chipping and shaping tools are most likely to suffer gradual loss of hearing (*see* DEAFNESS AND IMPAIRED HEARING).

Solution of the Noise Problem.—In approaching a noise problem first consider the source. Can a quieter machine or operation be substituted? Can the noise intensity be reduced? Can a useful change be made in how the noise is directed? Are resilient pads beneath the noisy device of any use? Can a muffler be used? Second, consider the path from the source to the listener. Can the source or the listener readily be moved, so that the two are farther apart, to reduce the sound level? Should a barrier be erected between the source and the listener? Is a total enclosure for the source required? Will the addition of an absorbing acoustical material result in significant noise reduction? Third, consider the listener. Can he be induced to wear ear plugs or noise-reducing cushions or helmets? Can he be enclosed in a booth or other quiet space?

TABLE II.—*Acoustic Power for Various Acoustic Sources*

Power (watts)	Source

Source: *Handbook of Noise Measurement*, General Radio Co., Cambridge, Mass.

Ready-built mufflers are available for engines and air ventilating systems. Many types of sound-absorbing materials are available. Walls between rooms should be as heavy as possible and should be made of two isolated leaves with an intervening air space for maximum sound reduction between rooms. Sound-absorbing materials should be used on the ceiling or walls of a room to prevent the reinforcement of the noise due to room resonances. Rubber, cork or felt pads may be used under machines to reduce vibrations.

Barriers such as walls or pens between a sound source and a listener are effective only if they are high enough and if they are either very near to the source or very near to the listener. When a source or a listener is fully enclosed, careful attention must be taken to gasket all cracks around doors and to seal all joints.

(L. L. B.)

AIRCRAFT NOISE CONTROL

Noise Aboard Aircraft.—In modern transport aircraft, with the cockpit located well forward of the engines, designers need be primarily concerned with only two sources of annoying cockpit noise: aerodynamic noises arising in the turbulent boundary air along the outside surface of the fuselage and in ventilating ducts and outlets, and noises associated with the operation of auxiliary mechanical and electrical equipment.

The passenger compartment also is exposed to noise from these sources and, frequently, to undue amounts of engine or propeller noise. Jet engine noise often is most noticeable in rear portions of the cabin. In both the cockpit and passenger compartment, properly designed and acoustically insulated ventilating ducts and outlets, and suitable treatment of walls, ceilings and floors with sound-absorbing or insulating materials, help greatly in reducing noise and vibration. In addition, the customary window design (small, rigid, double panes installed primarily for protection against decompression failures) helps reduce noise transmission from outside the aircraft.

External Aircraft Noise.—More difficult problems of noise control arise in connection with persons on the ground in the immediate vicinity of terminal buildings and maintenance facilities and in communities over which aircraft must pass at low altitudes when landing or taking off.

One serious annoyance is the engine intake noise produced by the sirenlike action of jet compressor blades, even at reduced rotor speeds. Furthermore, as an aircraft maneuvers to and from its ramp position, its jet blast may sweep the ramp adding dust, dirt and fumes to the irritating noise. Ground personnel therefore should be provided with adequate eye and ear protection, and passengers entering or leaving aircraft must be protected by air- or noise-deflecting barriers. Some terminals allow passengers to remain entirely indoors by providing movable, covered ramps, connecting the aircraft and terminal building, or mobile lounges traveling between aircraft and the terminal.

To complaints of disturbing noise lodged by residents of communities near airports, no fully satisfactory answers had been found in the 1960s. The noise produced by a propeller-driven airplane reaches a peak level in the low-frequency portion of the sound spectrum, whereas unsuppressed jet exhaust normally peaks at a higher frequency. However, the addition of noise suppressors may tend to shift the jet exhaust sounds still farther toward the higher frequencies, bringing them well within the speech-interference range. The result is that the suppressed-jet exhaust sound may be substantially more annoying to persons on the ground than is noise of equal intensity from a propeller-driven aircraft (*see* AIRCRAFT PROPULSION).

It was found that aircraft speed is a relatively unimportant factor except as it affects the time of exposure of a ground observer. Altitude is of prime significance, however, because the intensity

of transmitted noise varies inversely as the square of the distance between source and receiver. Power or thrust levels, of course, are also of great importance.

A partial solution to the problem is found in altering airport flight patterns and aircraft takeoff procedures. Complaints often are reduced when pilots are instructed to make an initially rapid climb at full thrust to some minimum altitude, such as 1,200 ft. (thus rapidly increasing the distance between the aircraft and persons on the ground), followed by a reduced rate of climb at reduced power or thrust to cruising altitude. Such a procedure, however, represents a compromise between the safest and most efficient combinations of engine power and aircraft speed and those combinations that result in the least annoying noise levels.

It is also possible to reduce complaints by directing low-flying aircraft over less densely inhabited areas, although at many airports such changes in flight patterns may not be effected without undesirable sacrifices in safety, especially as regards prevailing wind directions. A more satisfactory solution to the problem involves the development of devices to suppress jet engine sound at the source without too seriously affecting weight, drag or power output.

Another serious noise problem is the so-called sonic boom produced by airplanes traveling at speeds greater than Mach 1, the speed of sound. The phenomenon is the shock wave generated by the aircraft; traveling at the same speed as the aircraft, it produces at the ground a sudden pressure change audible as a sound like a thunderclap or an explosion. A sufficiently intense shock wave can impair hearing or damage buildings. (*See* also AERODYNAMICS: *Supersonic Aerodynamics*.) (W. Li.)

Law.—In law, noise may be defined as an excessive, offensive, persistent or startling sound. By the common law of England freedom from noise is essential to the full enjoyment of a dwelling house and noises that affect that enjoyment may be actionable as nuisances. But it has been laid down that a nuisance by noise, supposing malice to be out of the question, is emphatically a question of degree. The noise must be exceptional and unreasonable. Ringing of bells, building operations, vibration of machinery, fireworks, bands, a circus, merry-go-rounds, disorderly crowds, dancing, singing, etc., have been held under certain circumstances to constitute nuisances so as to interfere with quiet and comfort and have been restrained by injunction. The concept of legalized nuisance, such as the nuisance arising from noise produced by public transportation, has found some favour in U.S. courts.

In the United States, many cities have passed ordinances containing noise abatement provisions, conformity with which can be determined by readings from a sound-level meter and a frequency analyzer with frequency bands approximately one octave in width (the eight frequency bands commonly used are 20–75, 75–150, 150–300, 300–600, 600–1,200, 1,200–2,400, 2,400–4,800 and 4,800–10,000 cycles per second). Individual states have passed laws establishing means for measuring damage to hearing and schedules of compensation that are related to the percentage of hearing damage.

NOLA, a town in Napoli province, Campania region, Italy, lies 23 km. (14 mi.) E.N.E. of Naples in the fertile and highly cultivated Campania plain. Pop. (1961) 24,523 (commune). There are traces of an amphitheatre, and a necropolis with frescoed tombs. Nearby is Cimitile where the bodies of Christian martyrs were buried, among them St. Felix. There are still traces of basilicas and constructions of the 4th and 5th centuries, to which the Cenobites withdrew. In the Seminary at Nola the Cippus Abellanus was discovered (1750), on which is engraved in Oscan the treatise governing the administration and laws of the area of Hercules' sanctuary, which lay between Abella (Avella) and Nola (2nd century B.C.). The Gothic cathedral (13th century) is dedicated to the town's patron St. Paulinus, patrician of Bordeaux, elected bishop in 410, in whose honour the Festa dei Gigli (festival of the lilies) is celebrated in June. The Orsini palace (1460) has Catalan doors and windows. The philosopher Giordano Bruno (1548–1600) was born at Nola. The town is on the Naples-Foggia-Avellino railway. The district produces vegetables, fruit, maize (corn) and hemp.

A city of the Aurunci, it had the Oscan name of Novla (new town) late in the 5th century B.C. In A.D. 14 Augustus died there. It was an episcopal see from the 3rd century and the birthplace of St. Felix. A fief of Guy de Montfort in 1269, it passed to the Orsini; from 1528 it followed the fortunes of Naples.

(M. T. A. N.)

NÖLDEKE, THEODOR (1836–1930), German philologist, whose work dealt with Semitic languages and the history of Islam, was born at Harburg, March 2, 1836, and studied at Göttingen, Vienna, Leiden and Berlin. In 1859 his history of the Koran won the prize of the French Académie des inscriptions; he rewrote it in German with additions (*Geschichte des Korans*, 1860). He taught at Göttingen (1861), Kiel (1868) and Strasbourg (1872). Nöldeke died Dec. 25, 1930, at Karlsruhe.

NOLLEKENS, JOSEPH (1737–1823), British sculptor, was born on Aug. 11, 1737, in Soho, London, where his father, a native of Antwerp (the "Old Nollekens" of Horace Walpole), was a painter of some repute. At the age of 13 Joseph entered the studio of the sculptor, Peter Scheemakers. In 1760 he went to Rome and his marble bas-relief, "Timoclea before Alexander," brought him a prize of 50 guineas from the Society of Arts in 1762. David Garrick and Laurence Sterne were among the first English visitors who sat for busts. On his return to England he became an associate of the Royal Academy (1771) and in 1772 a full member. By that time he had become known to George III, whose bust he executed and, until about 1816, he was the most fashionable portrait sculptor of his day. Other portraits were those of William Pitt, Charles Fox, the prince of Wales (afterward George IV), George Canning, Spencer Perceval, Benjamin West and Lords Castlereagh, Aberdeen, Erskine, Egremont and Liverpool. He himself preferred his imitations of the work of the ancients, such as the "Venus Anointing Herself." His work is remarkable for delicacy, but deficient in vigour and originality. Nollekens died in London on April 23, 1823.

See J. T. Smith, *Nollekens and His Times* (1949). (A. K. McC.)

NOLLE PROSEQUI, in Anglo-American law, the termination, at the prosecutor's instance, of proceedings against a person accused of crime by indictment or information where it appears that the interests of justice do not require him to be brought to trial. In English law, the power to enter a *nolle prosequi* is vested in the attorney general and is rarely used. In the United States the power is generally exercised by the prosecuting officer, typically the district attorney, and is an important adjunct to the administration of criminal justice. Particularly in large cities, many more criminal prosecutions are initiated than it is feasible to try. The *nolle prosequi* serves as a screening device by which the district attorney is enabled to exercise a measure of control over the criminal docket. It is also used to effect an informal settlement, as where a thief agrees to make restitution to his victim. In some states, the common-law rule that the entry of a *nolle prosequi* is within the sole discretion of the district attorney still obtains; in others, his discretion is subject to leave of court. When entered before trial, the *nolle prosequi* does not bar a subsequent prosecution on the basis of a new indictment or information. (H. L. P[illegible]

NOMADS (Gr. *nomas*, *-ados*, "roaming about for pasture"), peoples who lead a migratory life, having no fixed abode. Although the Greek *nomas* referred to pastoral nomads, the modern term nomad is applied to all wandering peoples, of which there are three main types: primitive nomads, pastoral nomads and tinker or trader nomads.

Primitive Nomads.—The most primitive peoples known today are nomadic, as were Stone Age people all over the world. A people which does not produce food, but only collects that which nature provides, cannot usually stay in one place for very long. After a day or two or a few weeks, depending on the natural resources, the game within walking distance of a camp is killed or frightened away, and the tubers, seeds, fruits and other vegetable food within the same radius will also be exhausted. When food becomes scarce, the primitive band must move to another [illegible]

ste. It is often assumed that nomads wander aimlessly, without a fixed territory. Actually the primitive nomad who depends for survival on what he can find to eat must know the territory in which he roams—location of waterholes, where certain plants grow and the habits of the game. Thus each nomadic band, of perhaps from 20 to 50 persons, establishes rights over the territory within which it migrates, although its members may visit bands in other territories. (*See* BUSHMAN.)

Pastoral Nomads.—Pastoralists in central Asia and the middle east who depend on domesticated livestock for a livelihood also migrate in order to find pasturage for their animals, and like primitive nomads they have an established territory. Pastoral nomads may be classified according to their economy and by their pattern of migration.

Economy.—The reindeer breeders of Siberia, such as the Urianghai of the Altai mountains, depended on hunting as well as reindeer breeding for subsistence, and the 12th-century Mongols also obtained their meat by hunting. In central Asia generally pastoralists could, and often did, subsist entirely on animal products, although they welcomed trade goods when these were available. On the fringes of the grasslands families which had lost their animals engaged in agriculture, but only grudgingly. Stockbreeding was the basis of the pastoral economy and nomadism the preferred way of life. In southwest Asia and north and east Africa (also in Tibet which, although geographically a part of central Asia has a nomadic pattern more like that of southwest Asia), pastoral nomadism and settled agriculture have always been interdependent. The camel-breeding Rwala Bedouin of Arabia practiced no agriculture, but they were dependent on grain and other products obtained from their settled neighbours in exchange for camels. The proud Masai of east Africa, who would not condescend to till the soil, obtain grain and other goods from subordinate tribes. A majority of the nomadic tribes in southwest Asia and north Africa practice some cultivation, planting crops and harvesting them between seasonal migrations. These peoples may be described as seminomadic or even semisedentary, for many have fixed abodes where they dwell for a part of each year.

Patterns of Migration.—The migration pattern of pastoral nomads depends to a considerable extent on topography and climate. Some Kazakh groups, for example, made migrations of many hundreds of miles between winter quarters in the south and summer pasturage in the north. Other Kazakh groups moved only a few miles between winter quarters at the foot of the mountains and high summer pastures. In the Altai region, where the pastures were rich, units followed the same route year after year. In the southern Urals, where pastures were more uncertain, a scout was sent ahead and the first to arrive at a suitable site established rights on the campsite for his group.

In Arabia the Bedouins camped during the hot summer months near a town or oasis, then moved out onto the desert after the rains. In arid Arabia there could be no fixed itinerary such as that of the Altaian Kazakhs, but each group had its established territory, and beyond that smaller groups owned certain wells. Seminomads have permanent dwellings where they plant crops before moving out with their livestock in search of grazing. In western Syria and parts of north Africa winter villages are at the foot of the mountains and the animals are taken into the uplands during the summer. In southern Somaliland the people dwell in fixed villages, but send their animals out with the men twice a year—to plateau grasslands in the rainy season and to the river banks at the height of the dry season.

Tinker and Trader Nomads.—In parts of Asia primitive nomads were caught up into a larger society in such a way that they remained nomadic but became dependent on other groups. In Arabia the Sulubba or Slebs are such a people. In addition to hunting, the Slebs breed white asses; the women are prostitutes, while the men do tinkering for the Bedouins and guide them into desert recesses unfamiliar to the camel breeders. In India and West Pakistan there are nomadic peoples who make and sell baskets and other simple products or hire out as labourers on construction jobs. The best-known tinker and trader nomads are the gypsies. Believed to have originated in India, gypsy bands migrated in various parts of Europe and the United States, tinkering, horse trading and telling fortunes.

Nomadism in the 20th Century.—Nomadism has been a way of life for many people, but it is on the wane. Few primitive nomads survived in mid-20th century, although a number were described during the preceding century. Pastoral nomads have been settling down through the centuries. Many groups have made a gradual transition from full nomadism to seminomadism to sedentary life, and whole peoples, under economic or political pressure, have taken up agriculture or, as in the Soviet Union, have become settled stockbreeders. By the 1960s most of the pastoral nomads in the Soviet Union had been settled, and in Iran the nomadic population had dropped from one-third to one-fifth in the first half of the 20th century.

The nomadic way of life dies slowly, however. In the 1960s pastoral nomads were numerous enough in Chinese central Asia (Sinkiang) to be a political force. Gypsies still migrated in the United States, although traveling in Cadillacs instead of carts. A few primitive Bushmen roamed the Kalahari desert of South Africa in search of game and plant food, and Australian aborigines went "walkabout" when they felt the strictures of sedentary life unendurable.

See also MIGRATION.

NOME, a town of Alaska, U.S., on the south Seward peninsula shore of the Bering sea, 525 mi. W. of Fairbanks; at one time (1900) the largest settlement in the territory. Gulch gold was found near the site of Nome on Anvil creek in Sept. 1898; the town was established the following year and diggings on the ocean beach were first worked in July 1899. The rush to Nome in 1900 was one of the most remarkable stampedes in U.S. mining history; the town soon had hotels, banks, stores, several newspapers and weekly mails from the United States; for part of the year there were, it was estimated, 20,000 inhabitants. By 1903 the population had greatly decreased; in 1920 it was 852 by the federal census, growing to 2,316 residents in 1960 (principally Eskimos). In 1905 the gold output of the Nome region amounted to about $2,500,000, nearly all from placers. Gold remained the principal industry, although with reduced production, until the dredge fields were closed in 1962. Transportation, tourism, government construction and Eskimo fur and ivory production accounted for most of the town's employment. The town is served by several airlines and roads radiate into the tundra. A few miles of narrow-gauge railway are preserved as a tourist attraction. Nome adopted council-manager government in 1964.

Nome was first called Anvil City; the name Nome is derived from Cape Nome, first so called on a chart dated 1849, and said to have been a draftsman's mistake for the query "?Name" on the original chart. (J. E. CL.)

NOMENOË (d. A.D. 851), duke of the Bretons who fought successfully against the Frankish king Charles II the Bald. The Carolingian emperor Louis I the Pious, whose predecessors had never gained effective control of Brittany, appointed Nomenoë as duke or permanent *missus* (*see* MISSI DOMINICI) to keep order in Armorica; *i.e.*, the specifically Breton country west of Nantes and Rennes. Nomenoë quelled a serious revolt in 837, but refused to admit Frankish troops to his duchy. When Louis died and war broke out between his sons (840), Nomenoë at first promised loyalty to the youngest of them, Charles the Bald, and even, in 842, supplied him with troops. Soon, however, Nomenoë turned against Charles and occupied Rennes, which Charles had to besiege in Nov. 843.

During the next three years Nomenoë's raids into Maine and Anjou provoked vain counterattacks by Charles, who came to terms in 846. Nomenoë obtained a *de facto* independence which

enabled him to strengthen his authority in Brittany. Nevertheless he launched an offensive toward the Bessin country (around Bayeux) in 847. In 849 he substituted his own nominees for the pro-Frankish bishops in Brittany and severed the connection of their sees with the bishopric of Tours. In 849 also he ravaged Anjou; and in 850 he took Nantes. He died near Vendôme on March 7, 851.

See E. Durtelle de Saint-Sauveur, *Historie de Bretagne* (1935); F. Lot and L. Halphen, *Le Règne de Charles le Chauve (840–877)*, vol. i (1909). (J. De.)

NOMINALISM. Nominalists deny that universals (*q.v.*) exist, arguing that the existence of a general word does not imply the existence of a general thing named by it, though indeed there must be some similarity between the particular things to which the general word is applied. Extreme nominalists would withhold this concession (*e.g.*, perhaps Roscelin withheld it, but we have only his adversaries' word for this). But, unless it is granted, the application of general words to particulars is made to appear entirely arbitrary, which is absurd. Perhaps extreme nominalism, if anyone ever held it, might be explained as an excessive reaction against exaggerated forms of Platonic realism. Such a reaction was natural in the middle ages when enthusiastic Platonists verbally denied the reality of material objects. Whenever realists go too far in their depreciation of material objects an alliance between empiricism and nominalism is to be expected: the most notable medieval example of a synthesis of this kind was the work of William Ockham (but he can also be regarded as a conceptualist; *see* below).

In the middle ages, when Platonic and Aristotelian realist doctrines were associated with orthodox religious belief, nominalism could be made to seem heretical. But if nominalism is considered simply as a logical doctrine, stripped of these associations, it is more interesting for what it asserts than for what it denies. It denies that Platonic realism is needed in order to explain our ability to think and speak in general terms. It also seems to deny that Aristotelian realism is needed for this purpose; but this denial is not so unequivocal, since a moderate nominalist (*e.g.*, Hobbes, even though some of his dicta suggest extreme nominalism) would say that there must be some similarity between the particulars to which a given general word is applied, and this is very like saying that a universal must be present in them. What it asserts is, in Hobbes's words, that *ratio est oratio*, that thought is essentially the same kind of thing as speech. Now thought and speech would be impossible if the world did not contain series of similar things. But, given this condition, it is a further question how exactly thought and speech operate; and the nominalist's answer to this is that they both operate by using symbols, either linguistic symbols, or nonlinguistic symbols like mental images. This immediately brings him into conflict with some forms of conceptualism (*q.v.*), in which it is maintained that the ability to think correctly involves something more than the ability to use sets of symbols correctly; *i.e.*, that it involves the possession of concepts. Also, it is not clear in exactly what sense all thinking can be said to be the using of symbols. On the other hand, it is hard to see what the conceptualist adds to the nominalist's theory when he says that thinking depends on the possession of concepts. Perhaps he is drawing attention to such things as flashes of understanding. It might be possible to reconcile nominalism and conceptualism if the nominalist's analogy between thinking and using something were not pushed too far.

See also references under "Nominalism" in the Index.

(D. F. P.)

NOMOGRAPHY, the science of calculating charts. Its object is the general study of the representation, by means of diagrams called nomograms, of mathematical laws (Gr. *nomos*, "a law") which are expressed analytically by means of equations. Such graphical devices, once carefully drawn, yield the solutions of complicated problems with speed and with slight labour. They are especially helpful when many numerical problems of a similar sort are to be solved and when high accuracy is not required. They can be used by a person without special knowledge or experience and without the mastery of a difficult technique. Nomograms have been widely used in engineering, in industry and in the physical and natural sciences. Equations in many variables are handled by using a sequence of scale alignments or by employing networks of scales, and a great diversity of problems can be solved.

The use of graphic schemes for computation goes back to antiquity. The graphic solution of spherical triangles was in vogue in the time of Hipparchus, 150 B.C., and simple charts were designed by the mathematicians of the middle ages. The publication of René Descartes's *Discours de la méthode* (1637), which introduced analytic geometry to the world, gave a powerful impetus to graphical methods and provided their analytical background. The theory of nomograms rests largely on analytic geometry.

Co-ordinate Papers.—The use of squared paper for the representation of relations between two quantities is familiar in many fields. A point on the paper is located by giving its distance X to the right of a vertical axis and its distance Y above a horizontal axis (distances to the left and downward being reckoned negative). X and Y are called co-ordinates. An equation $f(X, Y) = 0$ is pictured by plotting the points whose co-ordinates satisfy the equation. The resulting graph is a line or curve from which corresponding values of X and Y may be determined visually. The eye is guided by the vertical rulings along which X is constant and the horizontal rulings along which Y is constant. The values of X and Y are commonly written along the axes.

It is clear that nothing is essentially changed if the values which are marked on the axes are not proportional to the distances from the origin but more or less arbitrary scales are used. Points whose co-ordinates satisfy a given equation can be plotted as before and a curve be drawn from which corresponding values can be read. The form of the curve can be altered and in some cases simplified. These notions were developed by Léon Lalanne in his *Anamorphose logarithmique* in 1842 and further advances were made by J. Massau and Charles Lallemand in the 1880s. A basic idea is to use such scales that the graphs of the equations under consideration become straight lines, which are easy to draw. The equation $af(x) + bg(y) + c = 0$, where a, b, c are constants becomes the straight line $aX + bY + c = 0$ if the distances X and Y along the axes to the marks x and y are determined by the functions in the equation; namely, $X = f(x)$, $Y = g(y)$.

Well-known examples based on this principle are the commercial logarithmic and semilogarithmic papers. The former papers use the scales $X = \log x$, $Y = \log y$ and are convenient for plotting the graphs of relations of the form $y^m = ax^n$. Since this may be written $m \log y = n \log x + \log a$, the graph on this paper is the straight line $mY = nX + \log a$. The semilogarithmic papers have the scales $X = x$, $Y = \log y$.

Fig. 1 shows a paper made with the scales $X = x^2$, $Y = y^2$.

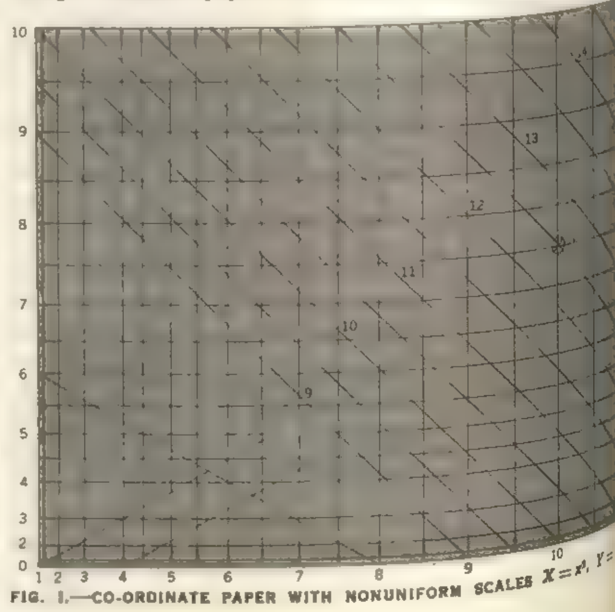

FIG. 1.—CO-ORDINATE PAPER WITH NONUNIFORM SCALES $X=x^2$, $Y=y^2$

Thus, the points marked 1, 2, 3, . . . on the axes are at distances 1, 4, 9, . . . from the origin. The graph of the ellipse

$$\frac{x^2}{64} + \frac{y^2}{36} = 1$$

is the broken line of the figure. The hyperbola

$$\frac{x^2}{16} - \frac{y^2}{9} = 1$$

and its asymptotes

$$\frac{x^2}{16} - \frac{y^2}{9} = 0$$

are the parallel lines made of short dashes. These simple graphs can be used for the usual purposes; *e.g.*, we read from the figure that the ellipse and hyperbola intersect at (6.3, 3.6).

An equation in three variables $F(X, Y, Z) = 0$ is represented in the cartesian system by a surface in three-dimensional space. To reduce the representation to a two-dimensional picture the use of contours is introduced. With Z held fixed, there is an equation in X and Y, whose graph is drawn. This is done for various values of Z and the values are written beside the curves. Other values of Z can be estimated visually. The resulting figure resembles a geographic map with contour lines upon it or a weather map showing isothermal lines or isobars.

Sometimes the contours can be reduced to straight lines by a happy choice of scales on the axes. An equation of the form $p(z)f(x) + q(z)g(y) + r(z) = 0$ yields a straight line for each fixed z, say z_0, using the scales $X = f(x)$, $Y = g(y)$, since the equation now is linear in the variables: $p(z_0)X + q(z_0)Y + r(z_0) = 0$. For example, a chart for solving right triangles can be made from the equation $x^2 + y^2 = z^2$ by drawing contours across fig. 1. Giving z the values 9, 9.5, 10, etc., we get the heavy slanting lines of the figure. To find the hypotenuse of a right triangle whose sides are 10 and 7.5 we are led to the point marked in the figure, from which $z = 12.5$.

Alignment Charts.—The word nomogram is sometimes restricted to a special type of chart which is used by bringing the points of three scales into alignment. In fig. 2 is shown an

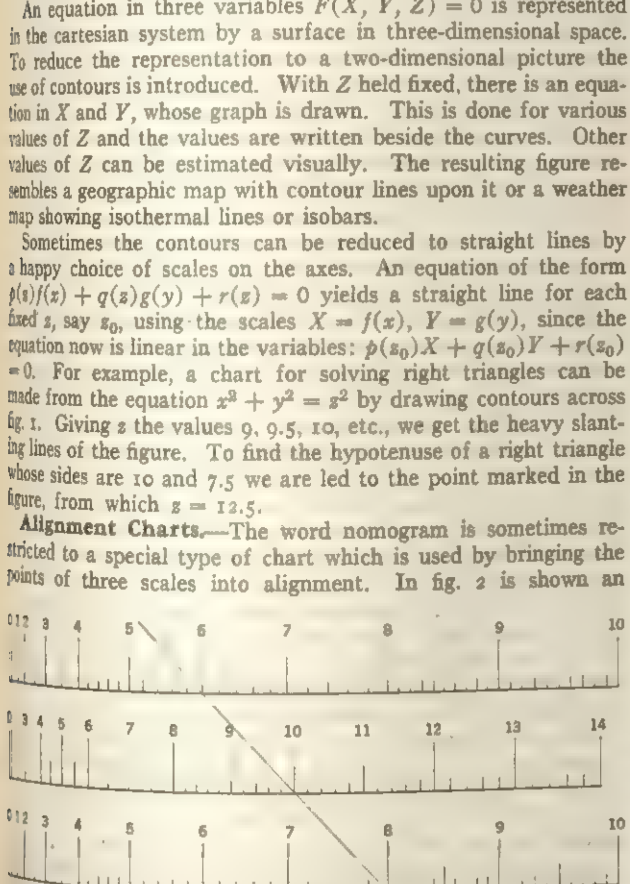

FIG. 2.—ALIGNMENT CHART FOR SOLVING $x^2 + y^2 = z^2$. FOR $X = 6$, $Y = 8$ THE LINE DRAWN SHOWS THAT $Z = 10$

alignment chart for the solution of $x^2 + y^2 = z^2$. On the upper and lower horizontal lines are laid off from a vertical axis the scales $X_1 = x^2$, $X_2 = y^2$ identical with those on the axes in fig. 1. Midway between is a line with a scale half as large, $X_3 = \frac{1}{2}z^2$. Now let a straight line be drawn across the figure cutting the scales at points marked x, y and z. It is seen from elementary geometry that $X_3 = \frac{1}{2}(X_1 + X_2)$, whence the equation $x^2 + y^2 = z^2$ is satisfied. The equation is solved for one of the variables by joining given values of the other two variables on the scales by a straight line and reading the solution where this line cuts the third scale.

A chart for solving any equation containing three variables can be made in a similar manner provided the variables can be segregated into three separate terms, $h(z) = f(x) + g(y)$. We have merely to plot the scales $X_1 = f(x)$, $X_2 = g(y)$ on the outside lines and $X_3 = \frac{1}{2}h(z)$ on the middle line. Thus, a scale for multiplication, $z = xy$, could be made after first writing the equation in the form $\log z = \log x + \log y$, the three plotted scales then being logarithmic.

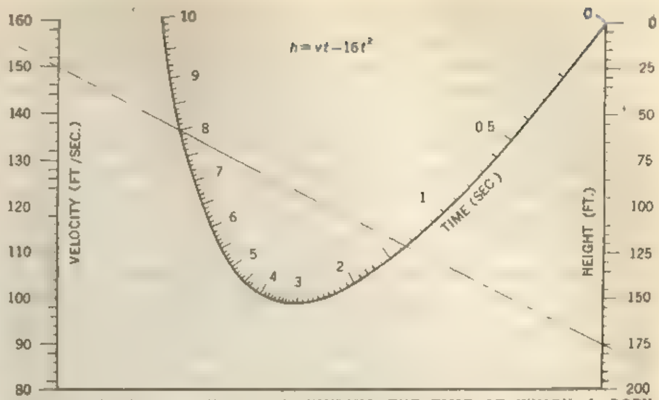

FIG. 3.—ALIGNMENT CHART FOR FINDING THE TIME AT WHICH A BODY THROWN UPWARD WITH A GIVEN VELOCITY ATTAINS A GIVEN HEIGHT (NEGLECTING FRICTION). THE LINE DRAWN SHOWS THAT FOR AN INITIAL VELOCITY OF 150 FT. PER SECOND THE BODY WILL BE 175 FT. HIGH IN 1.36 SEC. AND AGAIN (ON THE WAY DOWN) IN 8 SEC.

This type of chart has certain obvious advantages. Only three scales need be drawn, and they are more easily used than a complicated diagram. Interpolation can be accurately done since the line cuts cleanly across the scale. As a practical matter the line across the chart should not be actually drawn since a few lines in pencil would mar the chart. A fine thread may be stretched across the chart. An excellent line may be made on a transparent ruler with the point of a knife, a little graphite being worked in to give it visibility, and this can be laid across the chart.

The principle of the alignment chart was first described in 1884 by Maurice d'Ocagne (1862–1938) of the École Polytechnique in Paris. He developed the subject in many papers and books and particularly in his treatise of 1899, *Traité de nomographie*, in which were brought together both the general theories and a multitude of practical applications. D'Ocagne may properly be called the creator of nomography.

In its more general forms the alignment chart for the solution of an equation in three variables may employ straight scales arranged in various ways, or one or more of the scales may be curved as in fig. 3. A curved scale may be constructed from parametric equations $X = f(t)$, $Y = g(t)$. A value of t gives a point (X, Y) on the curve. Points for suitably spaced values of t are marked and the value of t is attached. Thus, $X = \cos t$, $Y = \sin t$ gives a circular scale, since $X^2 + Y^2 = 1$. Whether the resulting scale is curved or straight depends upon the parametric equations.

Take two functions of a variable x, two functions of y and two functions of z. Let these form three scales: an x scale $X_1 = F(x)$, $Y_1 = f(x)$; a y scale $X_2 = G(y)$, $Y_2 = g(y)$; and a z scale $X_3 = H(z)$, $Y_3 = h(z)$. Three points (X_1, Y_1), (X_2, Y_2) and (X_3, Y_3), corresponding to readings x, y and z, respectively, on the three scales lie on a line if the slope of the line joining the first two points is equal to the slope of the line joining the last two points; that is,

$$\frac{Y_2 - Y_1}{X_2 - X_1} = \frac{Y_3 - Y_2}{X_3 - X_2}$$

This condition may be put in the form

$$F(x)\,[g(y) - h(z)] + G(y)\,[h(z) - f(x)] + H(z)\,[f(x) - g(y)] = 0$$

or as a determinant

$$\begin{vmatrix} F(x) & f(x) & 1 \\ H(z) & h(z) & 1 \\ G(y) & g(y) & 1 \end{vmatrix} = 0$$

The chart will solve this equation for one of the variables when the other two are known. Conversely, an alignment chart can be made for any equation which can be written in this form.

If an equation can be solved by an alignment chart it can be solved by an infinitude of alignment charts. By applying a projective transformation

$$X' = \frac{a_1X + b_1Y + c_1}{a_3X + b_3Y + c_3} \qquad Y' = \frac{a_2X + b_2Y + c_2}{a_3X + b_3Y + c_3}$$

where a, b, c values are constants, to the plane of the chart we get another chart. The degree of a curve remains invariant, whence collinear points remain collinear and we still have an alignment chart for the equation. Because of the large number of constants at our disposal the chart can be thrown into a multitude of forms. Projective transformations are used to bring distant portions of a chart back on the page, to change the positions of scales so as to make the best use of the space on the page and to get convenient arrangements generally. The scales of fig. 3 consist of two parallel lines and a hyperbola. We could, for example, carry the linear scales into intersecting lines, or make the curved scale parabolic or circular, or greatly magnify some portion which we wish particularly to use. A useful result is that a convex quadrilateral covering any part of a chart can be carried into a rectangle of desired dimensions so that it fits on the page. *See* GRAPH; CHART.

NONCONFORMISTS, English Protestants who do not conform to the doctrines or practices of the established Church of England. The word Nonconformist was first used in the penal acts following the Restoration (1660) and the Act of Uniformity (1662), to describe the "conventicles" (places of worship) of the Separatist congregations. Nonconformists are also called "dissenters" (a word first used of the five "Dissenting Brethren" at the Westminster Assembly of Divines in 1644–47). As a result of the movement begun in the late 19th century by which Nonconformists of different denominations combined together, leading to formation of the Free Church Federal council (*q.v.*), they are also called "Free Churchmen." The term is loosely applied in England and Wales to all Protestants dissenting from Anglicanism: Baptists, Congregationalists, Methodists, Unitarians and even such independent groups as the Society of Friends (Quakers), the Plymouth Brethren, the English Moravians, the Churches of Christ and the Salvation Army. (In Scotland, where the established church is Presbyterian, members of other churches, including Episcopalians, are Nonconformists.)

The first English Nonconformists were influenced by the continental Reformation and, like the Puritan party in the Church of England, wished only for a more radical reform of doctrine and ritual within the established church. The first Separatist congregation in London, under their pastor, Richard Fitz, met in secret at the Plumber's hall, where they were arrested in 1567 for treasonable opposition to the Elizabethan Acts of Uniformity and Supremacy. Such religious separatism was regarded as dangerous for both religious and political reasons, and Independents (also called Brownists, after their founder, Robert Browne, and, later, Congregationalists) and Baptists were subjected to organized persecution. Those who carried on Browne's work, as leaders of a Separatist congregation in London, Henry Barrow, John Greenwood and John Penry, were executed in 1593; Barrow and Greenwood for their treasonable assertion that "Christ is the only Head of his Church and His laws may no man alter," Penry ostensibly for complicity in the Marprelate controversy. As a result, many Independents and Baptists went into exile in Holland.

After the failure of the Church of England Puritan party to win over James I at the Hampton court conference (1604), the king threatened all Puritans, including the Presbyterians (who wished to reorganize the Church of England as a disestablished Presbyterian church), that they must either "conform themselves" or be harried out of the land. Among those who chose exile were the group known as the Pilgrim Fathers, who spread the ideas of English dissent to the new world, ultimately influencing the development of the U.S. constitution and respect for civil liberties.

Under Cromwell and the Protectorate, Presbyterianism predominated, although the Independents and Baptists also gained ground, and several left-wing radical groups (the Diggers, Levellers, Fifth Monarchy Men) developed the Lollard strain in dissent; while others—Shakers, Ranters and Quakers—wished to restore the spiritual enthusiasm of the early church, the Quakers especially reasserting need for dependence on the guidance of the "inner Light."

The rigorous laws of the Puritans produced reaction, further justified by the association in the public mind of dissenters with regicide, fanaticism and republicanism. After the Restoration, fear led to penal laws against Nonconformists—the so-called Clarendon code. The Act of Uniformity reauthorized the Prayer Book (*see* COMMON PRAYER, BOOK OF) and redefined the doctrines and rites of the Church of England, requiring that all clergy appointed under the Commonwealth should receive episcopal reordination and accept the Thirty-Nine Articles of 1571. Those who refused (numbering 2,000, including, as well as Presbyterians, some Independents and Baptists) were ejected from their livings (the "Great Ejectment," or "Ejection." Other restrictive acts included the Conventicle acts (1664 and 1670), which made meetings for worship illegal, even in private houses, where more than four outsiders were present; the Five-Mile act (1665) forbidding Nonconformist ministers to live, or visit, within five miles of a town, or any place where they had ministered; the Corporation act (1661) which forbade municipal office to those not taking the sacraments at a parish church; and the Test act (1673), which insisted that all officials of the crown should receive Anglican communion.

In 1689, however, a Toleration act was passed which demonstrated that the idea of a "comprehensive" Church of England had been abandoned, and that hope lay only in toleration of division. Toleration was limited, allowing Nonconformists to have their own places of worship (provided that these were unlocked and their locality notified), and to appoint their own preachers and teachers, subject to acceptance of certain oaths of loyalty, and of most of the Thirty-Nine Articles. Social and political disabilities remained, however, and Nonconformists were still denied office (as were, also, Roman Catholics). This led to the practice of "occasional conformity," but in 1711 an Occasional Conformity act imposed fines on any who, after receiving Anglican communion, were found worshiping at Nonconformist meetinghouses. A bill introduced by Viscount Bolingbroke to prevent the growth of schism by forcing all those who taught or kept schools to take an oath of allegiance to the Church of England was frustrated by Queen Anne's death, on Aug. 1, 1714, the day when it was to take effect. Had it become law, it would have destroyed the intellectual and educational power of dissent, which had made an important contribution to education by the foundation of "dissenting academies." Between 1663 and 1688, more than 20 academies had been founded and more than 30 more were started during 1690–1750. These, begun for the training of Nonconformist ministers to whom the universities were closed, became centres of learning, offering a wider, more liberal education than the universities then provided, including business training, science and sociology as well as theology and the classics.

The Toleration act did not apply to Unitarians, whose numbers grew in the 18th century. Their strength was allied to the growth of Rational Dissent, Deism (*q.v.*) and belief in human perfectibility. Side by side with this intellectual development went a spiritual decline in both Nonconformity and the Church of England. It was partly against this that the leaders of the evangelical revival in Anglicanism and the founders of the Methodist movement reacted. Methodists were only gradually forced into a position of Nonconformity and until the mid-19th century were not generally regarded as Nonconformists.

Quakers, however, were so regarded, and with other dissenters and evangelical Anglicans played a leading part in such movements for social reform as the abolition movement, the temperance movement, reform of prisons, and the founding of Sunday school movement, charity schools, orphanages and asylums. Methodists took the lead in the evangelization of the growing slum population in the late 18th and early 19th centuries and popularized dissent by building chapels; by open-air evangelism; by writing hymns; by organizing all members of Methodist societies into "classes"; and by starting circuits for ministers and lay preachers.

The gain in Nonconformist wealth and standing during the 18th century led to increased restiveness at civil and political disabilities. The Board of Dissenting Deputies—comprising laymen from the Baptist, Congregational and Presbyterian denominations which in 1727 had formed the Board of Dissenting Ministers in London—was founded in 1732 to fight for equality, redress of injustices and relief of distress caused by the discrimination under which the Nonconformists suffered. Among the abuses they attacked were unjust rates, illegal impressment, discrimination in collection of tithes, eviction for voting against Tory landlords (for the Nonconformist alliance with the Whigs, begun by their support for the Revolution of 1686, had continued), and the election by municipalities of Nonconformists to offices denied them under the Test and Corporation acts (this last for the purpose of acquiring their fines for refusing to serve). The deputies appealed unsuccessfully for repeal of the Test and Corporation acts in 1735 and 1739, but a grant was made for relief of distress. In 1811 they achieved repeal of the Five-Mile act and, in 1828, of the Test and Corporation acts. Other disabilities were removed in 1868, when abolition of church rates relieved Nonconformists of the necessity to pay for the upkeep of parish (Church of England) churches; and in 1880, when the Burials act made churchyard burial of dissenters legal. They also played a part in the founding (1828) of London university (*q.v.*), the first nonsectarian university; in the opening to all of Oxford and Cambridge (1871); in the fight for inclusion in the 1870 Education act of a clause prohibiting specifically denominational teaching in national schools; and in the demand for disestablishment of the Church of England. Although to some extent superseded by the Free Church council (which successfully protested against the levying of rates from Nonconformists for church schools in 1902), the Dissenting Deputies still exist.

In England as a whole during the 19th century, the "dissenting interest" formed a separate group, advocating freedom of conscience and developing its own educational and social institutions. Nonconformists greeted the 1832 Reform bill with enthusiasm: the towns enfranchised by it were centres of dissent, and training in lay preaching and in the church meeting had fitted dissenters to express their opinions democratically. From the Methodist chapel and the Congregational and Baptist church meeting came the leaders of Chartism, the Labour party and the trades unions, while the link between the Nonconformist wealthy middle classes and the Whigs was continued in support for the Liberal party. The Liberal government of 1906–10 has been called the most complete expression of the "Nonconformist conscience" (a phrase first used after the O'Shea divorce case, which drove Charles Stewart Parnell from political life).

The political and social influence of Nonconformity was at its height in the mid-19th century, backed by solid middle-class Victorian power. Because the professions had been closed to them, many dissenters, especially those educated in the "dissenting academies," had become scientists or had gone into business or trade. Nonconformist manufacturers and shipping owners became wealthy and powerful, and through their support the churches to which they belonged gained influence.

In the 20th century the general decline in church attendance and religious observance, growing concern at disunity in the face of the need for worldwide mission, and the consequent growth of the ecumenical movement (*q.v.*) somewhat replaced the rancour or arrogant separatism of the preceding centuries. There is still a place in English life for the Nonconformist witness, however, and for assertion of all that is best in the Puritan tradition and the Nonconformist conscience."

NONDESTRUCTIVE TESTING. Nondestructive tests employ indirect measurements that do not damage test objects to detect flaws and measure performance properties of engineering materials, parts, assemblies and structures. Test indications must be correlated with strength or serviceability determined by past experience or by destructive mechanical tests of similar items.

Human senses often serve as nondestructive tests. Visual inspection reveals size, shape, surface discontinuities and finish. Dimensions are gauged and surface irregularities detected by touch. Cracked metallic parts are detected by striking with a hammer and listening to their vibrations. For centuries, skilled craftsmen have controlled the quality of their work through frequent inspections. They personally rejected defective materials or parts. Modern, high-speed production methods, however, offer little opportunity for such direct sensory inspection. In many operations parts move at high speeds behind shields and the workmen watch the performance of machines, rather than the product being fabricated. To ensure reliability, scientific nondestructive tests must be used to detect discontinuities and to measure performance properties of these products.

Nondestructive tests also are used to discover minute defects or hidden internal conditions that can cause premature service failures under severe operating conditions such as extreme temperatures, high stresses or damaging environments. Nondestructive tests are essential in prevention of disastrous failures of complex engineering systems such as those required for nuclear power systems, jet aircraft, missiles, space vehicles and military equipment, and process industries such as chemical and petroleum refining. They can also detect service damage prior to failure, and are cheaper and faster than dismantling complex equipment for direct inspection. Economic benefits result from their use to eliminate waste of materials, loss of machine and labour time, and user dissatisfaction.

Probing Media and Detection Systems.—Each nondestructive test method requires some form of probing medium to explore the test object, and a detection system to reveal its reactions to discontinuities or material properties. Probing media include electromagnetic waves, mechanical vibrations, electric and magnetic fields, liquid penetrants, heat, movements of electrons or ions, and other forms of energy or motions of matter. Detector signals must be amplified to useful levels, and converted to forms suitable for human interpretation or for actuation of display, recording or control devices. Many different physical effects are used in probing media and in detectors and amplifiers for test indications. For basic information on the physical phenomena and relationships involved in the applications illustrated in the following examples *see* X RAYS; ULTRASONICS; MAGNETISM, etc.

Penetrating Radiation Tests.—Electromagnetic waves, similar to light waves but of much shorter wavelengths (0.001 to 2Å; one $Å = 1 \times 10^{-10}$ metre), are used as probing media in penetrating radiation tests. Radiation sources include electronic X-ray generators and radioisotopes that emit gamma rays. Their high-energy photons have wavelengths small compared with inter-atomic

spacings, and penetrate through solid materials opaque to light. Radiation is partially absorbed and scattered within materials, depending upon wavelength, material thickness and density, and the types of atoms present. The transmitted radiation beam forms shadow images of voids and discontinuities, changes of material thickness and segregations of differing densities.

In film radiography, the shadow image is recorded by photographic films. In direct fluoroscopy, a phosphor screen fluoresces with a brightness proportional to radiation intensities. Electrostatic image tubes can be employed to enhance the brightness of fluoroscopic images. In xeroradiography, a photoconductive coating on a metal plate is electrically charged, and discharges locally when exposed to the radiation image. The resultant latent electrostatic image is developed by spraying the exposed plate with oppositely-charged, pigmented particles. Special X-ray-sensing television camera tubes can be used in closed-circuit television systems that reproduce images at a distance from the radiation source. Human observers interpret the X-ray images to detect internal discontinuities such as gas holes, porosity, slag inclusions, shrinkage defects, cracks, cold shuts (discontinuities in cast metal), misruns and other flaws in castings and weldments, and voids in brazed bonds. Positions and dimensions of internal components in complex assemblies are also measured from X-ray images, as are evidences of corrosion wall-thinning, fatigue cracking and other forms of deterioration of products in service.

Geiger counters, scintillation counters, ionization gauges, semiconductor crystals such as cadmium sulfide, and other point detectors provide signals proportional to radiation intensity. They can be used in thickness or mass-per-unit-area gauges to measure sheet materials in rolling mills, or coatings applied to sheet materials, often with feed-back controls to reduce process variations. X-ray diffraction and fluorescence analysis techniques are used to identify constituents, measure strain and follow structural changes during processing. Many other industrial applications exist where opaque materials are inspected by penetrating radiation tests.

Radiation hazards must be controlled in all industrial applications of penetrating radiations because of the biological damage these radiations can induce in human operators. Recommended practices are specified by the National Committee on Radiation Protection (N.C.R.P.) and in state and municipal safety codes.

Ultrasonic Tests.—Sound waves (or mechanical vibrations) at high frequencies (200,000 to 25,000,000 cycles per second) are used as the probing media for ultrasonic nondestructive tests. They are created in piezoelectric transducers and transmitted into solid test materials through films or layers of liquid couplants such as oil or water. Ultrasonic beams can be directed or focused like beams of light. They are partially reflected at interfaces where there are changes in material density or elasticity, and are refracted at interfaces between materials in which sound travels at different velocities. Within solid materials, vibrational modes that can be established include longitudinal (rarefaction and compression) waves, shear or transverse vibration waves, surface waves (like those on the ocean), and special modes related to dimensions of the sound conductor. Ultrasonic waves propagate well in fine-grained wrought materials, but tend to scatter and be attenuated in coarse-grained structures such as large castings. The echoes which return from material boundaries or discontinuities can be used to measure material thickness, to detect discontinuities, and to indicate some material properties. Under ideal test conditions, echoes from flaws of very small dimensions can be detected through considerable thicknesses of materials.

Many variations exist in ultrasonic test methods. In ultrasonic resonance testing, longitudinal waves at varying frequencies establish resonance in parallel-surfaced parts when the round-trip transit time equals the time between successive waves from the transducer. This permits measurement of material thickness, detection of laminar flaws in sheet or plate, and detection of corrosion wall-thinning or wear during service. In pulse-reflection testing, a brief burst of sound waves travels from transducer through the test object, reflecting from the opposite surfaces or from intervening discontinuities. The initial pulse and return echoes are displayed on a cathode-ray oscilloscope (*q.v.*) as a function of time, so that flaw depth or part thickness can be measured. Echo magnitude can be used to estimate flaw areas, in comparison with standard test blocks containing drilled holes. The method provides extreme sensitivity to cracks and laminar flaws (difficult to detect with X-ray tests), voids, inclusions, segregations and many other discontinuities.

FIG. 1.—(TOP) DEFECT IN AN ALUMINUM ALLOY DIE FORGING; (BOTTOM) OSCILLOGRAM SHOWING DEFECT

In contact ultrasonic tests, the transducer is held manually in contact with test-object surfaces, with an oil-film couplant. In immersion tests, the test object is immersed in water, and the transducer supported at a distance from the surface being scanned. Large-scale automatic systems have been developed to display cross-sectional or map-like facsimile images of test objects and internal discontinuities. Such systems are used to inspect sheet and plate, tubes, forgings and complex assemblies such as bonded laminates or brazed honeycomb structures with remarkable resolution of detail.

Electromagnetic Induction Tests.—An alternating magnetic field is used as the probing medium in electromagnetic induction tests. The test object is placed within the influence of a magnetizing coil carrying alternating current of suitable frequency. Eddy currents and varying states of magnetization are induced within the test object by transformer action. The magnetic fields of the test object are superimposed upon the exciting field, and can be detected either through their reaction on the exciting coils or by means of an additional pick-up coil system. The amplitude and phase relations of the output signals are analyzed by suitable electric circuitry, to separate insofar as feasible the effects of test material

conductivity, permeability, dimensions, shape and flaws. Rod, bar, tubes and symmetric test objects can be passed through test coils at high speeds to measure dimensions, alloy composition, hardness, strength properties and other characteristics, or to detect discontinuities such as cracks, seams, laps, wall thinning and others. Small probe coils can also be scanned over test parts to measure local discontinuities or variations in properties. Such methods have found wide application in European industries. Eddy current tests are particularly well-suited to high-speed automatic production processes since measurements often take only a few thousandths of a second. They produce electrical signals that can be analyzed statistically by electronic circuits and used directly to control processes or produce records.

Magnetic-Field Tests.—Ferromagnetic materials such as iron or steel can be tested by using magnetic fields as the probing medium. In magnetic-particle tests, the parts are suitably magnetized and a suspension of finely-divided magnetic particles is applied to the surface. Where surface or near-surface discontinuities transverse to the direction of magnetization introduce gaps in the magnetic flux path, some of the flux lines tend to "leak out" at the surface, attracting accumulations of magnetic particles which delineate the discontinuities. Visible or fluorescent dyes upon the particles permit them to be seen readily even when the discontinuities themselves would be invisible because of their minute size or subsurface locations. The test finds wide industrial application in detection of cracks, seams, laps, inclusions or segregations in ferrous materials.

In magnetic probe tests, a sensitive magnetometer or Hall effect detector is used to measure magnetic fields at the surfaces of ferromagnetic materials. Measurements of the residual field or its coercive force permit evaluation of material hardness, tensile strength or results of heat treatment. Ferromagnetic material thickness can be measured in terms of saturation flux linkages. Anisotropic conditions in rolled sheet materials can also be detected.

Liquid-Penetrant Tests.—The probing medium used in liquid-penetrant tests consists of a light petroleum distillate containing visible or fluorescent dyes. Test parts, after cleaning, are immersed or sprayed with liquid penetrant, which enters surface-connected discontinuities. After penetration, excess surface fluid is washed off, and a porous developer coating which serves as a blotter is applied. Penetrant trapped in discontinuities then seeps back into the developer coating, tending to spread laterally so as to amplify indications. An alternative system involves application of an emulsifying agent to aid in removal of the surface penetrant, providing increased sensitivity over penetrants which contain emulsifiers when applied. Surface-connected cracks, seams, laps and other linear discontinuities are shown by streaks, and porosity by dots or areas of indications, when processed parts are examined under suitable illumination. Test sensitivity is adequate to reveal discontinuities too fine to be seen with a light microscope (since wavelengths of visible light are too great to permit light to enter the fine defects).

FIG. 3.—DYE PENETRANT INDICATION OF CRACK IN HEAT RESISTANT ALLOY DIESEL VALVE

Filtered-Particle Tests.—With porous materials such as some ceramics, solid particles are suspended in a liquid penetrant. When the liquid penetrant soaks into the porous material, the particles are filtered upon its surface. At cracks and other surface-connected discontinuities, much more penetrant enters, and numerous particles are filtered out at the entrance. Accumulations of particles coated with visible or fluorescent dyes are readily visible and greatly amplify test indications. Wet clay materials are inspected in this manner prior to kiln firing since defects present at this stage can be corrected at low cost.

FIG. 4.—FILTERED PARTICLE TEST WITH BLACK LIGHT GIVING FLUORESCENT SURFACE INDICATION OF A DRYING CHECK IN UNFIRED SANITARY WARE. TEST IS MADE BEFORE GLAZE IS APPLIED

Thermal Tests.—Heat is used as the probing medium in thermal tests of metallic materials and bonded assemblies, with the resultant temperature distributions being indicated by temperature-sensitive coatings or remote infrared detectors. Temperature-sensitive paint coatings change colours at specific temperatures, and temperature-sensitive phosphors vary in fluorescent brilliance under ultraviolet excitation in response to gradients in temperatures. Heat-repelled fluid coatings are applied by spraying, and test parts pass under infrared heat lamps which create temperature gradients and evaporate the coating solvent. The test objects emerge with a varnish-like coating in which pigments reveal the temperature distributions attained during the heating transient.

Other Methods.—Many other nondestructive tests have been developed. Electric current tests are used to detect transverse fractures in railroad rails, in rail detector car systems. Electrified particles provide probing electric fields and detectors for discontinuities in insulating materials and coatings. Brittle lacquers and birefringent plastics are used in coatings to detect strain distributions. Pressure and leak tests are performed with liquid penetrants and gases such as helium or halogen vapours (which can be detected by sensitive instruments). Chemical reagents which react with specific constituents of test materials are employed in chemical spot tests. Many other nondestructive test methods and applications are described in the literature.

Test Limitations and Operator Requirements.—All nondestructive tests are specific, and have limited capabilities and applications. Complete inspection and quality assurance usually require the use of two or more tests, to cover all possibilities of material conditions and discontinuities that could lead to premature failure in service. All nondestructive test measurements are indirect, and their indications must be correlated with serviceability by other means—such as destructive tests of similar specimens under simulated service conditions, or by extensive service experience with similar objects or materials.

In most test methods that involve human interpretation, the training and judgment of the inspector are vital to test reliability. The inspector must have adequate knowledge of the nature of materials and their processing, of the design requirements and conditions of service, and of the influence of discontinuities upon performance. This extensive knowledge is rarely available in industrial personnel, and continued indoctrination and training are essential in maintaining inspector qualifications with rapidly-developing fields in modern industry.

NONE, the last of the "little hours," appointed to be recited at the ninth hour—*i.e.*, 3 P.M. *See* further BREVIARY and HOURS, CANONICAL.

NONIUS MARCELLUS (date unknown), African Latin grammarian and lexicographer, author of the *De compendiosa doctrina* (a sort of lexicon, in which are preserved extracts from the works of many earlier writers), was born at Thubursicum

Numidarum (in Algeria) between the end of the 2nd and the 5th century A.D. The *De compendiosa doctrina* consists of 20 chapters—the 16th is lost. The first 12 deal with language and grammar and in the brief remaining chapters words are grouped according to the nature of what they refer to. Except in the last chapter examples are given from ancient authors. There are editions by L. Mueller (1888) and W. M. Lindsay (1903). Nonius was a man of little understanding or accuracy but posterity is indebted to him for preserving fragments of Latin tragedies and the satires of Lucilius and Varro.

See Pauly-Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft*, xvii (1936); W. M. Lindsay, *Nonius Marcellus' Dictionary of Republican Latin* (1901). (G. B. A. F.)

NONJURORS, the name given to those beneficed clergy of the Church of England and of the Episcopal Church in Scotland who refused to take the oaths of allegiance to William III and Mary II in 1689 because they had previously taken the oath to James II. They included many men of devotion and learning and their secession was a serious loss to the church. There were about 400 in England, including William Sancroft, archbishop of Canterbury, and four others of the seven bishops who had refused to read in their churches James II's second Declaration of Indulgence in 1688—Thomas Ken of Bath and Wells, John Lake of Chichester, Thomas White of Peterborough and Francis Turner of Ely, together with the bishops of Chester, Gloucester, Norwich and Worcester. Other distinguished nonjurors were William Sherlock, master of the Temple; Jeremy Collier, ecclesiastical historian; George Hickes, dean of Worcester; Henry Dodwell, Camden professor of history at Oxford; and Henry Hyde, 2nd earl of Clarendon.

Believing in the doctrine of nonresistance to established authority, the nonjurors argued that James II was still the rightful king and likened the position of William III to that of Oliver Cromwell. They were ordered to take the oath of allegiance by Aug. 1, 1689, but were allowed six months' grace before deprivation. With the king's approval, Gilbert Burnet, bishop of Salisbury, attempted to reconcile them to the new order, but they refused the generous terms offered and were deprived of their sees and other benefices in Feb. 1690. Although they had only a small following among the mass of the people, who did not have to take the oath, Sancroft and his colleagues claimed to represent the true Church of England, and in 1693 requested James II, in exile in France, to nominate two new bishops to continue the episcopal succession. James chose Hickes and Thomas Wagstaffe, who were consecrated in 1694 as bishops of Thetford and of Ipswich respectively. In 1713 Collier, Nathaniel Spinckes and Samuel Hawes were consecrated as "bishops at large," without territorial titles. Ken, the most eminent of the nonjurors, disapproved of the succession of bishops and held that the schism should be ended, but the number of nonjurors was augmented in 1714 by those who refused to swear allegiance to George I.

The introduction by the nonjurors of a new communion office in 1718 including four "usages" taken partly from primitive liturgies and partly from the first Book of Common Prayer of Edward VI caused a schism among them, dividing them into "usagers" and "nonusagers." The four usages were the mixed chalice; prayers for the faithful departed; the Oblatory prayer, offering the elements to the Father as symbols of his Son's Body and Blood; and a prayer for the descent of the Holy Ghost on the consecrated elements. In 1731 both groups accepted the usages and united, but other internal dissensions followed. Their numbers were now very small, but the episcopal succession was maintained until 1805, when the last congregation came to an end. The nonjurors' public worship was conducted in chapels or oratories and in private houses.

In Scotland the nonjurors included the greater part of the clergy of the Episcopal Church, which ceased to be the state church in 1690. The Scottish episcopal clergy maintained their opposition to the government until the death of Charles Edward, the Young Pretender, in 1788, when the bishops agreed to recognize George III. A large number of Presbyterians in Scotland, principally among the Cameronians (*q.v.*), also refused to take the oaths of allegiance to William and Mary, but as their refusal was on different grounds they are not usually referred to as nonjurors.

See J. H. Overton, *The Nonjurors* (1902); H. Broxap, *The Later Non-Jurors* (1924).

NONNUS (fl. *c.* 425–*c.* 450), the most notable Greek epic poet of the Roman period, was born at Panopolis (Akhmim) in Egypt. His chief work is the *Dionysiaca*, a hexameter poem in 48 books whose main subject, submerged in a chaos of by-episodes, is the god Dionysus' expedition to India. Nonnus' fertile inventiveness, felicitous descriptive fantasy well served by a unique command of the language, appropriateness of word-coinage, unrivaled fluency of versification and vast literary knowledge made of him the much-imitated leader of the last Greek epic school. By uniting an essentially Homeric diction to stylistic elements found, in isolation, in his various epic antecedents or drawn from other genres, he achieved a kind of literary syncretism parallel to the religious one which is evident in the *Dionysiaca*, an erudite and valuable mythological storehouse. Nonnus' style, cumbersome with its ever-recurring, often daring metaphors, its constant, repetitive abundance, its exorbitant adjectival ornamentation and its unremittingly bombastic, frenzied tone, appealed to the taste of the time. His excessive indulgence in formulas and the restricted metrical limits set by him (some as a sign of virtuosity, some influenced by the prevalence of stress over pitch in contemporary pronunciation) to the structure of the hexameter add to the monotony of his verse. Later in life he was converted to Christianity and composed a hexameter paraphrase of St. John's Gospel (*Metabole*), which shows all his earlier stylistic faults, particularly inflation, whereas his colourful imagination and descriptive ability had now dried up.

NONPARTISAN LEAGUE, common name for the Farmers' Nonpartisan Political league (often abbreviated N.P.L.) founded in North Dakota in 1915 and known after 1917 as the National Nonpartisan league. It was dedicated to rescuing the farmer from alleged economic abuses by local bankers and by grain speculators and railroad and elevator officials of Minneapolis and St. Paul, Minn. Another of its goals was the recovery of political control of North Dakota from these same interests and their agent, Alexander McKenzie, an expert in the manipulation of "invisible government." Founder of the league was Arthur Charles Townley (1880–1959), but much credit for awakening the people should be given to John H. Worst and Edwin F. Ladd of North Dakota Agricultural college.

The American Society of Equity and various other farm groups had secured adoption, in 1910–12, of a constitutional amendment permitting the state of North Dakota to build, own and operate grain elevators in Minnesota or Wisconsin, or both. But the state legislature refused (Feb. 1915) to implement the amendment and one member reportedly advised the concurrent convention of the Equity members "to go home and slop the hogs." The frustrated farmers were now ripe for any form of militant leadership. This was immediately supplied by Townley, a bankrupt flax grower who had recently been a Socialist organizer without benefit of Karl Marx. He and Fred B. Wood, a farmer near Deering, N.D., wrote the first constitution for the Nonpartisan league and immediately began the drive for members. The strategy was to support candidates from either major party who would pledge themselves to vote for state-owned elevators, mills, banks and hail-insurance companies. The dynamic Townley excoriated the "enemy" and rosily pictured the better days to come if his listeners would buy league memberships at $2.50 and support its program. (The cost of memberships later rose to $6, then $9 then $16.) Well over 20,000 farmers hopefully joined up, many giving postdated checks for the fee. The league's slate for 19

headed by Lynn J. Frazier (1874–1947) for governor and William Langer (1886–1959) for attorney general, won a smashing victory. In 1919 its creature legislature delivered as promised a state-owned Bank of North Dakota, a mill and elevator association, a hail-insurance company and a home building association. After weathering great difficulties these enterprises finally prospered under new management, though the home building association was later discontinued.

Townley's control over the league lasted only four years. Efforts to extend the organization into other states enjoyed some brief success in Minnesota, where it spawned the Farmer-Labor party, and in Idaho and South Dakota. Frazier and Langer, later in and out of the league, drove Townley into the political wilderness. The league suffered a defeat in 1921 when its man, Governor Frazier, was recalled by the voters. The defeat was tempered, however, by the failure of six antileague measures initiated by the Independent Voters association (I.V.A.), the league's sworn enemy. One year later Frazier won personal vindication for himself and for the league by victory in a contest for the U.S. senate.

The league virtually disappeared after 1924, though Langer revived it in 1932. The league tended to become a tight political machine under Langer's control; later it again declined in power. In 1956 the league affiliated with the Democratic party; in 1958 Senator Langer defied it and won re-election without a campaign. See also NORTH DAKOTA.

See Robert L. Morlan, *Political Prairie Fire: the Nonpartisan League, 1915–1922* (1955), the latest and best book on the league. Fred A. Shannon, *American Farmers' Movements* (1957), puts the topic into historical perspective and includes reprints of pertinent documents. (L. L. S.)

NOOT, HENRI VAN DER (1731–1827), Belgian leader during the revolution of Brabant in 1789, was born in Brussels on Jan. 7, 1731, the son of a landowner. An advocate at the sovereign council of Brabant, he began in 1787, in protest against the Holy Roman emperor Joseph II's reforms, to threaten the Austrian government with appeal to article 59 of the *Joyeuse Entrée* (*q.v.*), which released the Brabançons from allegiance to a prince who violated the constitution. This won him the support of the common people and of the clergy and influenced the guilds to raise a militia. The government insisted on the disbanding of the militia, but the estates of Brabant recognized Van der Noot as their defender. When his arrest was ordered, he fled to Breda in Dutch territory (Aug. 8, 1788). Nominated "plenipotentiary of the Brabançon people" by a group of guildsmen, he visited London and The Hague, offering Belgium to the house of Orange; and he also obtained verbal assurances of support from Prussia. As it turned out, however, the revolution was launched by his rival, the democrat J. F. Vonck, who thought that the Belgians should rely on their own efforts; and it was Vonck's general, J. A. van der Meersch, who won the battles against the Austrians. Even so, Van der Noot entered Brussels in triumph on Dec. 18, 1789. Appointed minister of the United Belgic States, he set himself out to eliminate Vonck and Van der Meersch, whose desire for a more representative form of government he denounced as an attack on religion and on the constitution. Vonck was driven out and Van der Meersch was arrested; but the Prussian general N. H. von Schoenfeldt, replacing the latter, was defeated by the Austrians, who recovered Brussels in Dec. 1790 (*see* BELGIUM: *History*). His incompetence having served to wreck the revolution, Van der Noot went into exile till the French had conquered Belgium. He was imprisoned for a time under the Directory (1796) and then remained in obscurity till 1814, when he emerged to plead for the return of Belgium to Austrian rule. He died at Strombeek on Jan. 12, 1827. (C. VE.)

NOOT, JONKER JAN VAN DER (*c.* 1539–*c.* 1595), Dutch poet, an ambitious opportunist and the pioneer of the Renaissance in the Netherlands, was born in Brecht *c.* 1539. The new metres and interest in classical learning are seen in his first poems (Ronsardian odes and sonnets) in *Het Bosken* (1568) and in his last major work *Lofsang van Braband* (1580) written in the (vain) hope of gaining nomination as the poet laureate of his province. His *Het Theatre oft Toon-neel* (1568), written and published in London while he was in exile, was translated into English with Edmund Spenser's assistance. His chief work, the epic *Olympias*, is complete only in his German translation, *Das Buch Extasis* (1576), though there are French and Dutch versions of the first half. Van der Noot died in Antwerp *c.* 1595.

See C. A. Zaalberg (ed.), *The Olympia Epics of Jan van der Noot* (1956). (P. K. K.)

NOOTKA (AHT), an Indian linguistic group of the southwest coast of Vancouver Island, B.C., whose territory extended from Cape Cook to San Simon point (near Victoria) and inland to the watershed. The Nootka, together with the Makah of northwesternmost Washington, constituted one of the two main divisions of the Wakashan linguistic stock. The second was the highly divergent Kwakiutl of northern Vancouver Island and the adjacent mainland. Salishan was spoken by all other natives of the island. The Nootka were located near the middle of the Northwest Coast culture area and their ways of life perhaps represent best the older and more basic aspects of that culture. Nootkans were oriented to the sea and their villages were located on bays or inlets. They made a specialized type of cedar dugout canoe, a remarkably seaworthy craft. These canoes and an intimate knowledge of coastal waters enabled the Nootka and Makah to travel considerable distances for sea-mammal hunting, visiting and trading. Both hunted the whale, a dangerous economic activity in which only two other coastal tribes engaged. Both also exploited the dense forests at their backs for game, roots and berries. Art was highly developed in the Northwest Coast manner. Totem poles and other elaborate stylized carvings were characteristic. Ceremonial feasts and property exchanges, called potlatches, were frequent. Northern Nootkan groups formed a social and political confederacy but the southern groups retained local autonomy. Numerous group names ended in *-aht* (*e.g.*, Nitinat, Clayoquot, Kyuquot, Mooachaht); hence some early writers used Aht as a collective designation. Capt. James Cook entered Nootka sound in 1778, at which time the population of the Nootka was perhaps 6,000, the Makah 1,500. Henceforth the fur trade flourished and the Indians rapidly acquired iron tools and many other appurtenances of western culture.

See Philip Drucker, *Indians of the Northwest Coast* (1955); James G. Swan, "Indians of Cape Flattery," *Smithsonian Contributions to Knowledge*, vol. 16, (1870). (V. F. R.)

NORA, an ancient site about 22 mi. S.W. of Cagliari (Carales) on the southern coast of Sardinia. Although according to tradition it was founded by Iberians from Tartessus, it occupies a characteristically Phoenician site, a triangular promontory ending in a steep cliff (Capo di Pula). The name Nora is related to the proto-Sard *norake* (tower, castle). Remains of a Sardinian *nuraghe* or towerlike monument were found nearby, and blocks from another were incorporated in a building identified as the Punic temple of Tanit. Apart from these, the earliest antiquities discovered at Nora are Phoenician, dating from the 7th century B.C. (*See* SARDINIA: *History*.)

In the Republican period, after the Roman annexation of Sardinia, Nora was its capital; under the Empire, it became a *municipium*. The latest Roman inscription records repairs of its aqueduct by Theodosius II and Valentinian III, A.D. 425–450; the last ancient writer to mention Nora, the *Anonimo Ravennate* (*c.* A.D. 700), describes it as a *præsidium* (fortified outpost).

Excavations in 1952–54 brought to light a wealthy imperial city overlying a typical Punic port. The Punic town, unfortified except for a watchtower at the tip of the promontory, had narrow irregular streets and buildings of characteristic Carthaginian construction. A *tophet*, where the bodies of cremated children were buried in great jars under steles carved with a temple façade and an image of the goddess Tanit, whose identity is confirmed by a graffito (*q.v.*) on a vase of the 3rd century B.C., is evidence for the violence of the period of the First Punic War. The imperial city dates from the Flavian period; a fine theatre, an aqueduct, a temple of Juno (probably the Carthaginian Tanit in Roman form), a handsome nympheum, baths and private villas were uncovered. The ruins of a paleo-Christian church, dedicated to the local saint, Efisio, and rebuilt in 1089, stand nearby.

See G. Pesce, *Nora, Guida agli Scavi* (1957). (E. H. RI.)

NORADRENALINE (Norepinephrine or Levarterenol), one of the hormones produced by the medulla of the adrenal gland. It has an effect on the body similar to that of stimulation of the sympathetic nervous system, producing rise in blood pressure, increase in concentration of blood sugar, etc. *See* Adrenaline and Noradrenaline; Adrenal Glands; Hormones.

NORBANUS, GAIUS (d. 82 B.C.), turbulent Roman popular leader at the turn of the 2nd and 1st centuries B.C. When tribune of the people (*c.* 103 B.C.) he accused Q. Servilius Caepio of having in 105 brought about the defeat of his army by the Cimbri through rashness; Caepio was condemned and went into exile. About ten years later Norbanus himself was accused of treason because of the disturbances that had taken place at the trial of Caepio, but the eloquence of M. Antonius, grandfather of the triumvir Mark Antony, procured his acquittal. During the social war (the war of the Italian *socii* or allies) Norbanus, as praetor in 88, successfully defended Sicily against the Italian allies. During the civil war between Marius and Sulla he sided with Marius; as consul in 83 he was defeated by Sulla at Monte Tifata, 3 mi. E. of modern Capua (Casilinum), and again in 82 by Q. Metellus Pius at Faenza (Faventia in Cisalpine Gaul). He fled to Rhodes, where he committed suicide while the Rhodians were debating whether to hand him over to Sulla.

See E. Badian, "Caepio and Norbanus," *Historia*, vi, pp. 318 ff. (1957).

NORBERT, SAINT (*c.* 1080–1134), archbishop of Magdeburg, reformer and founder of the canons regular of Prémontré (variously known as Premonstratensians [*q.v.*], Norbertines, White canons). Born between 1080 and 1085 in Xanten, Ger., Norbert became a canon of the collegiate church of Xanten, but he lived a worldly life at the court of the emperor Henry V. He was converted during a thunderstorm in 1115 and ordained a priest in the same year. Failing to reform his fellow canons at Xanten, he became an itinerant preacher who urged reform of morals for clergy and laymen alike. Unsuccessful in an attempt to reform the chapter of St. Martin at Laon, France, he was prevailed upon to found a religious institute at Prémontré near Laon (1120), of which the characteristic feature was the combination of an extensive, priestly apostolate with monastic discipline. St. Augustine's rule was adopted and the constitutions were modeled on those of the Cistercians. At Antwerp in 1124 Norbert preached successfully against the heresy of Tanchelin or Tanchelm. He was chosen archbishop of Magdeburg in 1126. Like his friend St. Bernard of Clairvaux he supported Innocent II against the antipope and won over the emperor Lothair II. He died on June 6, 1134, and was canonized in 1582. His feast day is June 6 (but July 11 in the order).

Kirkfleet, *History of St. Norbert* (1916); A. Zak, *Der heilige Norbert* (1930); H. M. Colvin, *The White Canons in England*, ch. 1 (1951); L. T. Anderson, *St. Norbert of Xanten* (1955). (L. T. An.)

NORD, the most northerly *département* of France, lies southwest of the Belgian frontier in French Flanders and French Hainaut and extends inland from a 20-mi. frontage on the Straits of Dover to the western flanks of the Ardennes uplands beyond the Sambre valley. It is bounded to the west by Pas-de-Calais and to the south by Aisne. Area 2,215 sq.mi. Pop. (1962) 2,293,-112. After Seine, Nord is the most populous *département* of France and contains in the continuous built-up area of Lille-Roubaix-Tourcoing one of France's largest urban agglomerations, with about 750,000 inhabitants, as well as numerous smaller mining and industrial towns on the coalfield nearby. This frontier district did not become part of France until the 17th century, and Flemish remains the language of the inhabitants of its northeastern corner between Dunkerque and the frontier. (For historical aspects *see* Flanders, County of.)

Behind the straight dune coast the reclaimed marshlands of the maritime plain are intersected by a dense network of drainage canals. Farther inland there follows a sandy plain with a few salient residual hills that played a great role in World War I. The chalk floor of the Flanders basin emerges at Lille and extends to the Sambre valley. France's major coalfield, buried benea[th] the chalk, crosses the *département* as a narrow strip from the Be[l]gian frontier east of Valenciennes to its western border beyon[d] Douai.

Except where it has been sterilized by towns and industry, the country is intensively farmed and produces large quantities of grain (wheat, oats, barley), sugar beet, potatoes and other vegetables, and fodder crops. Flax, tobacco, chicory and hops are also grown, and market gardening is important. An exceptiona[lly] heavy density of livestock is maintained, and farming is especia[lly] concerned with fattening young cattle, milk production for the sale and butter making, and pig rearing. Sugar refining, alcoho[l] distilling, flour milling, and brewing are widespread, impor[tant] industries. The major industrial development, however is associated with the old-established cloth-manufacturing towns and the modern exploitation of the coalfield. From the earliest pit near Valenciennes at the beginning of the 19th century, mining spread westward, transforming the agricultural countryside. Alongside the mines great quantities of patent fuels are prepare[d] and there are coking and distillation plants. Iron and steel works are especially concentrated along the canalized Escaut (Schelde) river in the vicinity of Valenciennes. Engineering, glass, chemicals, and other heavy industries are also carried on. Valenciennes and Douai are the chief towns on the coalfield.

Off the coalfield, to the southeast, are other steel and engineering works, with Maubeuge and Fourmies as outlying centres. North of the coalfield, textile industries are especially important but there is much engineering and Lille especially manufactures textile and agricultural machinery, besides having large boiler and locomotive works. Roubaix-Tourcoing is the chief seat [of] woolen textile manufacture and accounts for most of the French production of worsted. Linen is still an important product [of] Armentières and Lille. Cotton mills are more widespread and now synthetic and mixed fabrics are very much used. Manufacture of synthetic fibres has been introduced into the mining towns and, farther south, Cambrai, long famous for its linen ha[s] modern hosiery factories. Raw cotton is largely imported throu[gh] Le Havre, but in most other respects Dunkerque (*q.v.*) serves [the] industrial area with the imported raw materials it needs as well with large quantities of imported food. An artificial port grea[tly] improved since 1880, it is now the third port of France in vo[lume] of trade and has shipbuilding and oil-refining industries. A re[-]markable system of navigable waterways, interconnecting the canalized eastward-flowing rivers of Flanders, augments the ra[il]ways and roads that bind together the industrial complex and provide it with its external contacts.

Lille (*q.v.*), a former capital of French Flanders, is the pr[é]fecture and regional capital as well as the chief business and shop[-]ping centre of the immediately surrounding urban area. It is [the] centre of a modern bishopric, established in 1913, that compr[ises] the northern part of the *département*, the bishopric of Cambr[ai] corresponding with the southern part. The court of appea[l] still located at the old ecclesiastical and university city of Dou[ai] but Lille, with a modern university established in 1887, is now [the] centre of educational administration. The *département* cons[ists] of six *arrondissements*, centred upon Dunkerque, Lille, Dou[ai], Valenciennes, Cambrai and Avesnes.

Although modern warfare has taken its toll of old buildings some fine *hôtels de ville* and belfries have miraculously surviv[ed]. Elaborate, outdated fortifications and defensive moats are [fea]tures of several of the old towns of French Flanders and Li[lle] still shows Vauban's great citadel outside the old town.

(Ar. E. S.)

NORDAU (originally Südfeld), **MAX SIMON** (18[49]–1923), Jewish-Hungarian writer, a prominent Zionist and the au[-]thor of rationalist attacks on society which had a vogue at [the] time. Nordau (he changed his name in 1873) was born in Bu[da]pest on July 29, 1849. After qualifying as a doctor in 187[5] [he] moved to Paris in 1880 where he practised medicine. Two boo[ks], *Die konventionellen Lügen der Kulturmenschheit* (1883; Eng. trans. *The Conventional Lies of Our Civilisation*, 1884) and *Ent[ar]tung* (1892–93; *Degeneration*, 1895), made his name. In 18[..]

Nordau met Herzl and became an enthusiast for his plans for a Jewish state. He was vice-president of the first six Zionist congresses, where he shone as a speaker. After disputes over policy he resigned in 1921, dying in Paris on Jan. 22, 1923.

His works include *Gefühlskomödie* (1892) and *Die Drohnenschlacht* (1897) (fiction); *Doktor Kohn* (1898) (play); *Paris unter der 3. Republik* (1881); and *Die Krankheit des Jahrhunderts* (1889).

See A. and M. Nordau, *Max Nordau* (1943).

NORDENFLYCHT, HEDVIG CHARLOTTA (1718–1763), Swedish poet, remembered for her sensitive love poems, was born Nov. 28, 1718, at Stockholm. She fought all her life to keep her faith although disturbed by the ideas of the Enlightenment, and this conflict is expressed in her reflective poetry. The deaths of her fiancé in 1737 and of her husband soon after their marriage in 1741 inspired her finest poems, some of them published in *Den sörgande turtur-dufvan* (1743). During the 1750s she enjoyed a literary collaboration with Gustav Philip Creutz (*q.v.*) and Gustaf Fredrik Gyllenborg (*q.v.*). In 1761 she fell tragically in love with a man much younger than herself, and her poems about him mark the height of her achievement. She died at her home near Stockholm, June 29, 1763. Her *Samlade skrifter* were edited by H. Borelius and T. Hjelmqvist, 4 vol. (1924–38).

NORDENSKIÖLD, (NILS) ADOLF ERIK, BARON (1832–1901), Finnish-Swedish scientist and arctic explorer, was born in Helsinki on Nov. 18, 1832. During his studies at Helsinki university he incurred the displeasure of the authorities for his Swedish and western sympathies, and in 1858 he settled in Stockholm. During this year he made his first arctic expedition, to Spitsbergen under Otto Torell, and was appointed professor and curator of the mineralogical department of the Swedish State museum. He now undertook a series of further expeditions to Spitsbergen—in 1861 with Torell again, and in 1864, 1868 and 1872–73 as leader—and made fundamental contributions to the knowledge of the geology of the area, while in 1870 he led an expedition to west Greenland to study the inland ice. During the 1868 expedition, partly financed by the Göteborg businessman Oscar Dickson, the patron who was to provide such decisive support for all his subsequent expeditions, Nordenskiöld reached 81° 42′ N. in the mail boat "Sofia." In 1873, after a winter had been spent in difficult conditions in north Spitsbergen, he crossed the ice sheet of North East Land. Nordenskiöld's thoughts now turned to what was to be his greatest achievement—the accomplishment of the northeast passage. In two preliminary voyages in 1875 and 1876 he penetrated the Kara sea to the mouth of the Yenisei. On July 21, 1878, Nordenskiöld sailed from Tromsö on board the steam vessel "Vega"; he reached Cape Chelyuskin on Aug. 19, and after being frozen in at the end of September near Bering strait, completed the voyage in the following summer.

The "Vega" made a triumphal voyage home via the Mediterranean and when Nordenskiöld reentered Stockholm on April 24, 1880, he was made a baron by King Oscar. In 1883, on his return from west Greenland, where he penetrated far onto the inland ice, he became the first to break through the southeast coast's great sea ice barrier. In 1893 he was elected to the Swedish Academy. He died at Dalbyö on Aug. 12, 1901.

Nordenskiöld's bibliography lists 178 works. Geologist, mineralogist and geographer, he also broke new ground in his contributions to the early history of cartography. His two great works in this field are *Facsimile-atlas* (1889), and the indispensable collection of hand-drawn maps and charts entitled *Periplus* (Eng. trans. by F. A. Bather, 1897). (P. A. B. G.)

NORDENSKJÖLD, (NILS) OTTO (GUSTAF) (1869–1928), Swedish geographer and explorer, was born at Hässleby, Småland, on Dec. 6, 1869; he was the nephew of Baron A. E. Nordenskiöld (*q.v.*). At Uppsala university he first specialized in geology, and in 1894 he became lecturer in mineralogy and geology there. An expedition which he led to Patagonia and Tierra del Fuego (1895–97) made important contributions to the understanding of the glacial geology of the world as a whole. In 1898 he visited Klondike in the Yukon, and in 1900 he accompanied G. K. Amdrup to east Greenland. Nordenskjöld's long-planned project for a scientific expedition to the south polar regions was embarrassed by serious financial difficulties, but on Oct. 16, 1901, the "Antarctic" sailed from Göteborg. In Feb. 1902 a station was established on Snow Hill Island off Graham Coast, and there Nordenskjöld wintered with five companions. The "Antarctic," which wintered at South Georgia, was crushed in the pack ice of Erebus and Terror gulf (Feb. 12, 1903) when trying to relieve them the following summer. The crew wintered in 1903 on Paulet Island. But in November of that year the Argentine vessel "Uruguay" under Capt. J. Irizar rescued all parties of the expedition (*Antarctica*, 1905). Important geographical discoveries had been made in the course of long sledge and boat journeys, and probably few polar expeditions have achieved greater scientific results; these were subsequently published in a model manner in *Wissenschaftliche Ergebnisse der schwedischen Südpolar-Expedition 1901–1903*, six volumes (1905–20).

Nordenskjöld made minor expeditions to west Greenland in 1909 and to Peru and western Patagonia in 1920–21. He became the first natural scientist at the University of Göteborg when he was appointed to the new chair of geography there in 1905, and in 1923 became the first rector of the Göteborg school of advanced commercial studies. Nordenskjöld was concerned to popularize and synthesize his science and achieved this successfully in a number of works. Religion was important for him, and in later years he made active contribution to the ecumenical movement. He died in Göteborg on June 2, 1928. (P. A. B. G.)

NORDERNEY, a long, narrow, low-lying island and the largest of the East Frisian group, Germany, which after the partition of the nation following World War II became part of the *Land* (state) of Lower Saxony, Federal Republic of Germany. It is 8 mi. long and up to 1½ mi. broad and its dunes rise to about 68 ft. The northern coast is exposed to storm waves, but more sheltered water lies to the south in the Wattenmeer between the island and the mainland. Most of the population (7,331 in 1961) lives in Nordseebad Norderney, a leading coastal resort and small fishing port with shipping service to Norddeich (5 mi.) on the mainland. (HA. T.)

NORDHAUSEN, a town of Germany in Erfurt *Bezirk* (district) of Thuringia which after partition of the nation following World War II became part of the German Democratic Republic. It is situated on the Zorge river on the southern slopes of the Harz mountains, at the west end of the Goldene Aue, a fruitful plain watered by the Helme, 40 mi. (64 km.) N.W. of Erfurt city. Pop. (1964) 42,018. Historic buildings that survived the heavy air attacks of World War II include the 17th-century *Rathaus* with the oaken Roland monument (1717), an ancient symbol of civic liberty, the late Gothic Roman Catholic cathedral (with a Romanesque crypt) and the Protestant church of St. Blasius (13th century). Remnants of medieval town walls are extant. The public "Gehege" park dates from the 18th century. There are a museum, a theatre, a teachers' training college, an institute of agricultural technology and a sports school. To the former main industries, the distillation of rye-whisky and tobacco manufacture, have been added shaft-sinking processes and the manufacture of tractors and excavators. The town developed around a castle and market founded by the Saxon king, Henry I (the "Fowler"), in the early 10th century near the older Frankish settlement of Northusen. It was made a free imperial town in 1220, accepted the Reformation in 1522 and lost its independence in 1802 after annexation by Prussia. This association ceased when, in 1945, Nordhausen fell within the limits of Thuringia. The city's limits were extended in 1950 with the incorporation of the neighbouring villages of Salza and Krimderode. (WA. M.)

NORDHORN, a town of Germany, *Land* (state) of Lower Saxony, which after partition of the nation following World War II became part of the Federal Republic of Germany. It lies on the Vechte river 4 mi. from the Dutch border and about 44 mi. (70 km.) N.W. of Münster. Pop. (1961) 39,449. Part of the Augus-

tinian monastery (founded 1394) and the Protestant church (1489) are extant. The town is on a branch railway, the main road from Bremen, and the Ems-Vechte and Süd-Nord canals. Textiles form the main industry and there are petroleum wells nearby. First mentioned in 890 and chartered in 1379, it suffered heavily from plague, fire and war in the 15th and 16th centuries. Its area was expanded in the 1920s by the addition of neighbouring communities.

NORDLAND, a *fylke* (county) of northern Norway, extends from about latitude 65° N. to the northernmost point of the Vesterålen archipelago, about two-thirds of its area being north of the arctic circle. Area 14,798 sq.mi.; pop. (1960) 237,193. Fjords penetrate into the mainland, which is sheltered by numerous islands. Lying within the zone of the Caledonian folding, Nordland has an alpine landscape with several peaks higher than 4,900 ft. (Oksskolten 6,283 ft.). Habitation is mostly confined to the coastal lowlands and to fluvial deposits around the heads of the fjords, though farmland exists up to 900 ft. in the inland valleys. Mosjøen, Mo, Bodø, the administrative centre, and Narvik (*q.v.*) are towns of 5,000–14,000 inhabitants. About one-eighth of the fish catch of Norway is landed in Nordland. Cod fisheries from February to mid-April on the eastern side of the Lofoten Islands are of special importance. Animal husbandry, formerly a subsidiary occupation, is now to a great extent the main occupation even in some coastal areas. Pyrites are mined in the Sulitjelma and Mo areas. New mines are being developed in the iron ore deposits in the Dunderlandsdal (*q.v.*). Water power has given rise to electrometallurgical and chemical industrial plants. Railways run from Bodø to Oslo and from Narvik to Sweden; fast coastal lines sail to Bergen. (L. H. Hg.)

NÖRDLINGEN, BATTLES OF, two battles of the Thirty Years' War (*q.v.*), fought near Nördlingen in Swabia.

In the first battle, on Sept. 5 and 6, 1634, the Holy Roman emperor Ferdinand II's army, under the nominal command of his son Ferdinand III (then king of Hungary) and the actual direction of Matthias Gallas, together with a Spanish force led by the cardinal-infante Ferdinand, decisively defeated the Swedish army under the dual command of Gustav Karlsson Horn and Bernhard of Saxe-Weimar. The resumption of hostilities by the Poles after the end of the Polish-Russian "War of Smolensk" had forced the Swedes to dispatch large contingents against them; Gallas therefore disposed of vastly superior forces; and the incompatibility of the bold Bernhard and the irresolute Horn threw away the success that the Swedes had on the first day of battle. Horn was taken prisoner and remained in captivity until 1642. The complete rout of the Swedish army, mainly effected by Gen. Jan de Weert, led to the dissolution of the Heilbronn alliance of 1633 and the end of Swedish preponderance in southern Germany and forced the cardinal de Richelieu into bringing France into active participation in the war.

In the second battle, on Aug. 3, 1645, the French under Turenne and the duc d'Enghien (later prince de Condé) fought an imperial and Bavarian army under Franz von Mercy and Jan de Weert at Alerheim, 5 mi. E. of Nördlingen. The battle is memorable for Mercy's death and for Turenne's brilliant generalship, which turned De Weert's almost completed victory into defeat.

Bibliography.—For the battle of 1634 *see* E. Leo, *Die Schlacht bei Nördlingen* (1900); J. Fuentes, *La Batalla de Nördlingen* (1906). For the battle of 1645 *see* S. Riezler, *Die Schlacht bei Alerheim*, in *Sitzungsberichte* of the Munich academy (1901). (S. H. S.)

NORDRHEIN-WESTFALEN: *see* North Rhine-Westphalia.

NORDSTRÖM, LUDVIG ANSELM (1882–1942), Swedish writer whose best work describes life in his native province, was born at Härnösand (the "Öbacka" of his novels), Norrland, on Feb. 25, 1882. He studied at Uppsala and became a journalist, traveling widely at home and abroad. A follower of Strindberg, in his early works (the collections of short stories *Fiskare*, 1907; *Borgare*, 1909; and *Herrar*, 1910; and the novel *De tolv söndagarna*, 1910), he treated themes from his birthplace with imaginative power, ironic realism and humour. Keenly interested in economics and industrialism, and influenced by Herbert Spencer, Émile Durkheim and H. G. Wells, he developed a higher individual view of society, and in his numerous later writings—theoretical treatises, travel books and journalistic works, short stories and novels—preached a utopian world society based on a universal economic solidarity which he called "totalism." He died at Stockholm, April 15, 1942. Selections from his diary were published in *Ur Ludvig Nordströms dagböcker* (1955).

See M. Stiernstedt, *Kring ett äktenskap* (1953); G. Qvarnström, *Från Öbacka till Urbs* (1954). (H. Es.)

NORD-TRØNDELAG, a *fylke* (county) of central Norway. Area 8,673 sq.mi.; pop. (1960) 116,635. It includes undulating lowland around Trondheimsfjord, forested uplands and valleys to the east and north (the northern is Namdal) and the rather rugged and humid coastal district west of Namdal. The Trondheimsfjord area was comparatively densely populated even in early historic times. Frosta was one of the judicial centres of the country in the middle ages. At Stiklestad, Olaf Haraldssøn (St. Olaf) fell in battle (1030). Nord-Trøndelag is one of the best agricultural regions of Norway. Manufactures of wood and pulp are of importance in most districts. Pyrite is mined in Namdal and iron ore west of the Trondheimsfjord. Considerable water power potential is developed in the Namsen river system and further developments were scheduled for the 1960s. Steinkjer, the administrative centre, Namsos and Levanger are the chief towns. The *fylke* is traversed by the railway to Nordland with a branch line to Namsos. (L. H. Hg.)

NORE, THE, a sandbank in the Thames estuary marked by a lightship, the first to be established in English waters (1732). The name is used also of the area of the estuary roughly coinciding with the naval port of Sheerness. The Nore anchorage was much used by the fleet in the wars of the 17th and 18th centuries. In 1797 sailors at the Nore mutinied against conditions, and their leader Richard Parker, was hanged from the yardarm of his ship. The commander in chief, the Nore, is the naval commander of the eastern area of England.

See G. E. Manwaring and B. Dobrée, *The Floating Republic* (1935).

NORFOLK, EARLS AND DUKES OF. Norfolk is the premier English dukedom and earldom. Ralph the Staller (1011–c. 1069), 1st earl, an obscure figure, was probably a Breton and obtained the earldom *c.* 1067. His son, Ralph de Guader (*c.* 1040–?1096), 2nd earl, a follower of William the Conqueror, forfeited the title when he revolted against the king in 1075. The earldom lapsed until it was granted by King Stephen to Hugh Bigod (*c.* 1095–1177) in 1141. The Bigod earls of Norfolk were prominent in the reform movements of the 13th century; Roger (d. 1221), 2nd earl of this line, was one of the council of 25 set up by Magna Carta in 1215 and Roger (*c.* 1212–1270), 4th earl, played an important role in the movement against Henry III between 1258 and 1265. On the death of Roger, 5th earl, in 1306 the title lapsed until Edward II granted it to his younger half brother, Thomas of Brotherton (1300–1338), in 1312. He supported Queen Isabella in 1326 and helped bring about the deposition of Edward in 1327.

On Thomas' death the title passed in the female line and his daughter Margaret (*c.* 1320–1400) was created duchess of Norfolk for life in 1397 at the time her grandson, Thomas Mowbray (*c.* 1366–1399), was created duke (*see* Norfolk, Thomas Mowbray, 1st duke of). The dukedom lapsed on the death of John (1444–1476), 4th duke of this creation, but the earldom passed to his daughter Anne, wife of the young Richard, duke of York who was murdered in the Tower of London. On her death the earldom became extinct.

The dukedom was given in 1483 to John Howard (*c.* 1430–1485), whose mother, Margaret, was a daughter of Thomas, the 1st Mowbray duke of Norfolk. He served Edward IV assiduously, was created baron in 1470 and was treasurer of the royal household from 1467 to 1474. He subsequently supported Richard III who created him duke of Norfolk in 1483 and made him earl marshal of England. Norfolk was killed fighting for Richard at Bosworth (Aug. 22, 1485), and the title was later under attainder (*see* Howard). Thomas (1443–1524), the 1st duke's son, was created earl of Surrey in 1483 but was an attainted captive after Bos-

worth until 1489 when he was released by Henry VII and restored to his earldom but not to the dukedom of Norfolk. He then served the king in Yorkshire and the north. Henry VIII used him on public business despite Surrey's dislike of Thomas Cardinal Wolsey. He commanded the army that defeated the Scots at Flodden field (Sept. 1513), and was created duke of Norfolk in Feb. 1514. He was guardian of England during the king's absence in France (1520) and acted as lord high steward at the trial of his friend Edward Stafford, duke of Buckingham. Among Norfolk's sons were THOMAS HOWARD (1473–1554), 3rd duke of Norfolk (*q.v.*), WILLIAM (*c.* 1510–1573), 1st Lord Howard of Effingham, and the admiral SIR EDWARD HOWARD (*c.* 1477–1513). The 3rd Howard duke of Norfolk was succeeded in 1554 by his grandson THOMAS (1538–1572; *see* NORFOLK, THOMAS HOWARD, 4th duke of) since his own son was executed in 1547 for treason (*see* SURREY, HENRY HOWARD, earl of). The 4th earl was executed in 1572 and the dukedom was not restored to the Howard family until 1660 when THOMAS HOWARD (1627–1677) became 8th duke. Both CHARLES (1746–1815), 11th duke, and HENRY (1791–1856), 13th duke, held prominent Whig sympathies. By act of parliament (1824) the dukes of Norfolk were empowered to act as hereditary earl marshal (*q.v.*) despite their adherence to Roman Catholicism. HENRY (1815–1860), 14th duke, added the surname of Fitzalan. BERNARD (1908–), 16th duke, succeeded to the title in 1917.

NORFOLK, THOMAS HOWARD, 3RD DUKE OF (1473–1554), uncle of Anne Boleyn and Catherine Howard, and who held important political offices under Henry VIII, was the eldest son of the 2nd duke. He married Anne, daughter of Edward IV, in 1495, thus becoming a brother-in-law of Henry VII, who had married Anne's sister Elizabeth. He became lord high admiral in 1513, led the van of the English army at Flodden in September, and was created earl of Surrey in Feb. 1514. In 1513 he married Elizabeth, daughter of Edward Stafford, duke of Buckingham. Surrey went to Ireland as lord deputy in 1520 but soon vacated his post to command the fleet which sacked Morlaix and ravaged the neighbourhood of Boulogne in 1522; in 1523 he raided and devastated southern Scotland. He succeeded his father as lord treasurer in 1522 and as duke of Norfolk in May 1524, and as the most powerful nobleman in England he headed the party hostile to Thomas Cardinal Wolsey. He favoured the divorce of Henry VIII from Catherine of Aragon and the king's marriage with Anne Boleyn.

Norfolk became president of the council in 1529 but his position was shaken in 1536 by the fall of Anne Boleyn, at whose trial and execution he presided as lord high steward. But his military abilities rendered him almost indispensable to the king, and in 1536, just after the rising known as the Pilgrimage of Grace had broken out, he was dispatched into the north of England; he temporized with the rebels until the danger was past, and then, as president of the council of the north, punished them with great severity. Sharing in the general hatred against Thomas Cromwell, Norfolk arrested the minister in June 1540. A conservative in religion, he and Bishop Stephen Gardiner were thereafter the chief opponents of Archbishop Thomas Cranmer, the earl of Hertford, Lord Lisle and the "advanced" group in Henry's council. He led the English army into Scotland in 1542 and into France in 1544; but the execution of Catherine Howard, another of his nieces who had become the wife of the king, had weakened his position.

In Dec. 1546 his son Henry Howard, earl of Surrey (*q.v.*), was arrested on a charge of treason; Norfolk himself suffered the same fate as accessory to the crime. Surrey was executed in Jan. 1547; his father was condemned to death by a bill of attainder, but before the sentence was carried out, Henry VIII died. Norfolk remained in prison during Edward VI's reign, but in Aug. 1553 he was released and restored to his dukedom and later in the month he acted as lord high steward at the trial of John Dudley, duke of Northumberland. In Jan. 1554 he was sent to suppress the rebellion which had broken out under Sir Thomas Wyat, but his men fled before the enemy. He died on Aug. 25, 1554, at Kenninghall in Norfolk. (R. B. WM.)

NORFOLK, THOMAS HOWARD, 4TH DUKE OF (1538–1572), executed for his intrigues with Mary Stuart, was the son of Henry Howard, earl of Surrey (*q.v.*), and was born on March 10, 1538. After his father's execution, the council removed him from his mother's charge and he was given as tutor John Foxe, the Protestant martyrologist. Restored to his father's title on Mary I's accession, he succeeded his grandfather as duke of Norfolk in Aug. 1554. Although too young to take much part in affairs in Mary's reign, he was in favour both with her and with Elizabeth I. After some hesitation he took command of the English forces in the north during the intervention in Scotland in 1559–60 and presided over the commission of enquiry in 1568 into the quarrel between the Scots and Mary Stuart, who had just fled to England. Jealous of the earl of Leicester's favour and William Cecil's influence with Elizabeth, and having recently lost his third wife, he listened readily to suggestions from William Maitland of Lethington and others that he should marry Mary. He was not, however, bold enough to ask Elizabeth's consent or disloyal enough to agree to a rising against her; and while he hesitated, Elizabeth in Oct. 1569 had him arrested. He was released in Aug. 1570, after the suppression of the rising of the northern earls, but soon allowed himself to be drawn into Roberto Ridolfi's plot for a Spanish invasion to put Mary on the English throne. Its discovery led to his execution on Tower hill on June 2, 1572, despite Elizabeth's reluctance to order his execution. He died protesting his innocence and that "he was never a papist."

By his first marriage to Mary, daughter of the earl of Arundel, the duke of Norfolk left a son, Philip, who became earl of Arundel (1580) in right of his mother; by his second marriage he left two sons, Thomas Howard, 1st earl of Suffolk (1603), and Lord William Howard. (R. B. WM.)

NORFOLK, THOMAS MOWBRAY, 1ST DUKE OF (*c.* 1366–1399), one of the lords appellant in 1388 and perhaps best remembered for his quarrel with Henry, duke of Hereford (afterward Henry IV). The son of John, 4th Lord Mowbray, he was a youthful companion of Richard II and was made earl of Nottingham in 1383. Jealousy of Robert de Vere, earl of Oxford, the king's favourite, probably led Nottingham to join the nobles, led by the earl of Arundel and the duke of Gloucester, who sought to limit the king's power. Richard was at their mercy after De Vere's defeat at Radcot bridge (Dec. 1387) and Nottingham's moderation helped to dissuade the lords appellant against the king's deposition, in favour of "appealing" (arraigning) the royal favourites in the Merciless parliament (1388). For nearly two years power lay in the hands of the lords appellant. But as soon as the king regained his authority, in 1389, he showed Nottingham marked favour and detached him from his former colleagues. Later he became captain of Calais and the royal lieutenant in northeastern France. Richard took him to Ireland in 1394 and soon afterward sent him to arrange a peace with France and his marriage with Isabella, daughter of Charles VI. But the earl's supreme service to the king was in 1397 when Richard took a tardy but severe vengeance upon three of the appellants. In their turn these lords were appealed of treason before parliament and, as on the former occasion, Nottingham was one of the accusers. Gloucester was entrusted to his keeping at Calais and in Sept. 1397 he reported that his prisoner was dead. The duke had been murdered and Nottingham was perhaps responsible, although the evidence against him is not conclusive.

Nottingham was created duke of Norfolk in 1397. He then began to fear for his own safety and took the duke of Hereford into his confidence. Hereford informed the king, who summoned Norfolk to his presence, and at Oswestry, Norfolk accused Hereford of speaking falsely. A court of chivalry decided that the dispute should be settled by single combat at Coventry; but when everything was ready for the fight, Richard interposed and ordered both combatants into banishment (Sept. 16, 1398). Norfolk was exiled for life and deprived of his offices, although not of his titles. This quarrel forms act I of Shakespeare's *Richard II*. Norfolk died in Italy, at Venice, on Sept. 22, 1399.

trative History of Mediaeval England, vol. iii–iv (1928).
(T. B. P.; X.)

NORFOLK, an eastern county of England, bounded north and east by the North sea, northwest by the Wash, south by Suffolk and west by Cambridgeshire and Lincolnshire. The geographical area, excluding tidal water, is 2,054.3 sq.mi., the county being the fourth in size in England.

Physical Features.—Norfolk is low-lying, the highest areas being a little more than 300 ft. above sea level, while in parts of the Fenland the surface is below ordnance datum (mean sea level as defined for ordnance survey). The solid geology of the area is relatively simple, the superficial geology complex, giving rise to well-defined natural subregions. The most important rock of the county is the Chalk outcropping in west Norfolk as a long broad ridge mostly more than 200 ft. above ordnance datum and dipping sharply eastward until at Great Yarmouth its surface is 450 ft. below ordnance datum. Beneath the Chalk on its western edge lie the older beds of Kimeridge Clay, Lower Greensand and Gault and from the Norwich area to the coast the Chalk is chiefly overlain by the marine Crag deposits. Successive glacial advances have moulded the surface topography by the deposition of large areas of boulder clays, sands and gravels that have later been eroded. Postglacial changes of land and sea level have led to the formation of peats and clays in low-lying regions.

Parts of the 90-mi. long coastline are diversified by dunes of blown sand, and spits and islands of shingle and sand. Generally the west and northwest coasts are subject to accretion but from Sheringham southeast to Caister-on-Sea there has been marked erosion.

Nine subregions characterized by distinctive combinations of soil, vegetation and land utilization may be recognized in Norfolk: (1) About one-eighth of the English Fenland lies within the county. In the north silt predominates, in the south peat. Its intensive cultivation is only possible through the maintenance of an elaborate system of drainage. (2) The North Alluvial plain extends along the north coast from Hunstanton to Cley and consists entirely of marshland, much of it salt marsh. (3) The Greensand belt runs southward for about 25 mi. from near Hunstanton and is characterized by undulating heathland and magnificent woodland and by the use of carstone as a building material. (4) The Breckland in southwest Norfolk is a thinly populated area with an unusually sandy soil. Agriculturally the area is marginal and its former extensive heaths have been largely replaced by modern coniferous forests. (5) The "Good Sands" region comprises the upland area of northwest Norfolk and for centuries has been the principal area for barley cultivation and sheep-rearing. (6) High Norfolk occupies the centre of the county almost from the north coast to the southern boundary with Suffolk and is characterized by its heavy loam soils and is still well wooded. (7) The Cromer-Holt ridge consists of coarse gravels with the thinnest of soils, ending seaward in lofty cliffs where landslides are common. (8) The Loam region of northeast Norfolk possesses good soils, largely arable, is well wooded and thickly populated. (9) The Broadland (*see* below) consists of marshland, often below high-tide level, in the lower courses of the Bure, Yare and Waveney rivers and their tributaries.

Archaeology and History.—Norfolk is rich in archaeological evidence of past human cultures though many prehistoric structures have largely been destroyed by the extensive arable farming of recent centuries. Paleolithic flint implements mainly of the Acheulean-Clactonian cultures occur commonly in gravel beds and indicate human occupation in interglacial periods. Flint tools left by Mesolithic hunters are found on the lighter soils. Kelling is the best-known site. In all subsequent periods, as well as in the Roman and early Anglo-Saxon periods, population was mainly concentrated on the relatively easily worked soils of the Breckland and west Norfolk. The Cromer-Holt ridge and the Norwich area also attracted settlers. The heavier afforested soils of High Norfolk and the Loam region were not fully exploited until late Saxon times. Seaborne invaders chiefly entered the area by the rivers draining into the Wash or along those which flow out at Yarmouth. By land, the Chalk ridge linked west Norfolk with southern England and was traversed by the important Icknield way.

The chief monuments of the Neolithic Age in Norfolk are [illegible] extensive group of flint mines (Grimes Graves) in the Brec[illegible] and elsewhere in the Chalk area, in addition to two long barr[illegible] and the henge monument at Arminghall. There are exten[illegible] traces of the Beaker invaders from the Rhineland and to th[illegible] and their Middle Bronze Age successors may be attributed [illegible] of the numerous round barrows. It was only in the Late Bron[illegible] Age that this metal was freely available in Norfolk and [illegible] metalsmiths' hoards attest this. The beginning of the Iron Age (about 500 B.C.) saw the arrival of fresh invaders from the con[illegible] tinent, well represented by a farmstead excavated at West Har[illegible] In the 3rd century B.C. a new ruling class came from the Seine Marne area of France and provided the dynasty which ruled those living in Norfolk and northwest Suffolk known later as the Ice[illegible] To the last phase of the Iron Age belong a group of remarka[illegible] hoards of gold and bronze ornaments and gold, silver and [illegible] coins. The remains of the Roman era in Norfolk are not [illegible] pressive, possibly due to the perishable nature of much of the building material employed and to the comparatively late romani[illegible] zation resulting from the severe repression which followed the revolt of Queen Boadicea in A.D. 61. The administrative [illegible] was the walled town at Caistor-by-Norwich (Caistor St. Edmun[illegible] and there was a fortified port at Caister-by-Yarmouth.

Villa estates were most common in west Norfolk and the Fen[illegible] land was thickly settled by peasant cultivators. In the 3rd [illegible] 4th centuries there was a coastal fort at Brancaster to repel Sax[illegible] pirates. The road system is still imperfectly known.

From about A.D. 400 Norfolk received fresh immigrants—Angles, Frisians and Saxons—from northwest Germany and the Low Countries but the detailed geography and chronolog[illegible] these intrusive groups are uncertain. By about 550 the sma[illegible] units had been brought under the control of an East Angl[illegible] monarchy which for a brief period, under Redwald in the ear[illegible] 7th century achieved a temporary dominance but later fell under the sway of its neighbours. Norfolk became officially Christian [illegible] 631 and formed part of the diocese of East Anglia until this [illegible] divided in 673 and the bishop's see for Norfolk established [illegible] North Elmham, where substantial remains of the 10th-centur[illegible] cathedral may be seen. To the 8th century belongs the develo[illegible] ment of town life at Thetford and at Norwich where a mint [illegible] in operation by about 920. From mid-9th century Norfolk [illegible] subject to Danish invasion. In 869 the Danes wintered at The[illegible] ford and King Edmund was killed, East Anglia becoming part [illegible] the Danelaw and receiving large numbers of Danish settlers, espe[illegible] cially in Flegg north of Yarmouth. In the renewed Danish [illegible] vasions of the early 11th century both Norwich and The[illegible] were burned. Despite these setbacks, late Saxon times in [illegible] folk saw a great growth of population and a corresponding expa[illegible] sion of cultivated land through the deforestation of much of [illegible] tral Norfolk. By the time of the Domesday survey of [illegible] Norfolk was one of the most thickly populated and wea[illegible] regions of England and remained so throughout the medieva[illegible] riod. The opening up of central Norfolk led to the developm[illegible] of Norwich while Thetford remained static, the bishop's see be[illegible] transferred from there to Norwich in 1094. Yarmouth and [illegible] were also important towns as early as the Norman conquest [illegible] medieval prosperity of Norfolk rested on its successful agricu[illegible] and on its worsted production. This medieval wealth is refle[illegible] in its magnificent buildings both secular and ecclesiastical. [illegible] viving castles include such imposing structures as Norwich, Ca[illegible] Rising, Caister, Baconsthorpe and Oxborough ranging from [illegible] 12th to the 15th centuries.

The numerous monasteries suffered severely at the Reformat[illegible] but Norwich cathedral survives from a rich Benedictine mona[illegible] and there are substantial traces of other religious houses [illegible] the Dominicans (Black Friars) at Norwich, and monasteries [illegible] Castle Acre, Binham, Thetford and Wymondham. Little re[illegible] of the Augustinian house at Little Walsingham, one of the [illegible] famous shrines of the middle ages. Many parish churches [illegible] rebuilt in the 14th or 15th centuries and are conspicuous for [illegible] size and rich embellishments.

The peace of medieval Norfolk was ruffled from time to time by baronial warfare, the rising of 1381, the private strife of the 15th century revealed vividly in the Paston letters (*q.v.*) and the formidable rebellion of Robert Ket (Kett) in 1549. During the Civil War Norfolk was largely on the parliamentary side but some magnates supported the king and Lynn was held on his behalf.

Many great country houses from the 16th century onward survive to attest the wealth of the county based on successful sheep farming and later agricultural developments. Outstanding among these great buildings are East Barsham manor house (early 16th century), Blickling and Raynham halls (early 17th century), Holkham and Houghton halls and Wolterton park (18th century) and many 19th-century mansions, among which Sandringham (*q.v.*) has special interest as the Norfolk home of the royal family.

Broadland.—The Norfolk broads (lakes) are situated in close relationship to the three confluent rivers of east Norfolk—the Waveney, Yare and Bure with its tributaries, the Ant and the Thurne. A few broads lie just over the border in Suffolk but belong to the same system. Physically the broads are of two types—side-valley, such as South Walsham and the Ormesby-Rollesby-Filby series, and bypassed, such as those at Wroxham and Hoveton where they were originally separated from the river channel which passes close to them. Investigations based on thousands of borings and supplemented by documentary evidence show conclusively that the broads originated as peat cuttings in late Saxon and early medieval times and were abandoned due to a rise in sea level. During the 19th century many were steadily reduced in size by the encroachment of vegetation on former open water, and some have disappeared completely.

The Norfolk broads, and the river system which links them, form an important recreation area, with pleasure boats, both sail and power-propelled, centred chiefly on Wroxham, Potter Heigham, Stalham and Yarmouth. There are more than 150 mi. of navigable waterway. Only the Yare is used by seagoing trading vessels, bringing mainly coal and timber to Norwich. The unique physical and vegetational characteristics of the region are reflected in its rich and varied natural history. Many rare birds, insects and plants in this area are likely to survive if physical conditions remain constant as a result of the establishment of nature reserves at such places as the following broads—Alderfen, Barton, Hickling, Ranworth, Cockshoot and Surlingham (all under the care of the Norfolk Naturalists' trust); Horsey mere (National Trust), Calthorpe broad, Bure marshes and Martham broad with Winterton dunes (Nature Conservancy). Besides the Broadland nature reserves there are other important reserves in the county. Scolt Head Island (Norfolk Naturalists' trust, National Trust and Nature Conservancy) is extremely important for its physical structure, bird and insect life. Blakeney point (National Trust) is well known for its geographical features, bird life and botany. In Breckland, typical heathland is preserved at Weeting and East Wretham (Norfolk Naturalists' trust).

Population and Administration.—The area of the administrative county is 2,035.8 sq.mi. with a population in 1961 of 389,316. The municipal boroughs are King's Lynn (pop. [1961] 27,554); Norwich, a city and county borough, a cathedral town and the county town (119,904); Thetford (5,398); and Yarmouth, formerly Great Yarmouth (52,860), a county borough. There are 10 urban districts. The county is in the southeastern circuit, and assizes are held at Norwich. The county quarter sessions meet at Norwich and King's Lynn. Norwich, Yarmouth and King's Lynn have separate courts of quarter sessions. Norfolk is in the diocese of Norwich except for three rural deaneries in west Norfolk which are in that of Ely. These are six county parliamentary divisions—South-West, North, Central, and South Norfolk, King's Lynn, and Yarmouth (which includes the county borough of Yarmouth)—as well as the parliamentary borough of Norwich which returns two members.

Agriculture, Industries and Communications.—The county is largely agricultural, the chief crops being barley, wheat, sugar beet, oats, vegetables and root crops. Large areas are devoted to peas for canning or freezing. Most kinds of livestock are raised, and the county produces a greater number of turkeys than any other in Britain. Catering for visitors and holidaymakers, especially to the Broads area and the coastal towns of Sheringham, Cromer and Great Yarmouth, is a big summer industry. Norwich (*q.v.*), the county town, is the main industrial and marketing centre. Agricultural machinery is made in many towns and the old silk industry survives in Norwich.

Of three large, well-known boys' schools in the county, two are in Norwich, namely, King Edward VI's school and the City of Norwich school. The third, Gresham's school, was founded at Holt, near Sheringham, in 1555, by Sir John Gresham.

In 1953, after serious floods had done much damage along the coast, seawalls were rebuilt and stronger defenses put up against the sea's encroachment. Fishing is carried on from Great Yarmouth and several smaller ports. The other principal trading port is King's Lynn (Lynn).

The railways of the Eastern region of British railways serve the main towns. The eastern rivers afford water communication with Great Yarmouth, while the Great and Little Ouse and some of the drainage cuts communicate with Lynn.

NORFOLK, an independent city and seaport in the tidewater region of eastern Virginia, U.S., about 18 mi. W. of the Atlantic ocean near the mouth of Chesapeake bay. Its harbour of Hampton Roads (*q.v.*), formed by the junction of the James river and two tidal estuaries, the Nansemond and Elizabeth rivers, is one of the world's most magnificent harbours. About the harbour are also located the port cities of Portsmouth, Chesapeake, Hampton and Newport News (*qq.v.*). In 1960 Norfolk, the largest city in Virginia, had a population of 304,869. The Norfolk-Portsmouth standard metropolitan statistical area, consisting in 1960 of the cities of Norfolk, Portsmouth, South Norfolk, Virginia Beach and the counties of Norfolk and Princess Anne, had a population of 577,504. In 1963 South Norfolk and Norfolk county merged to form the city of Chesapeake, and Princess Anne county became part of Virginia Beach (*q.v.*). (For comparative population figures *see* table in VIRGINIA: *Population.*)

History.—The history of Norfolk began with an act of the Virginia general assembly of June 1680, on instructions from the King, which required each county to purchase 50 ac. and lay out a town and warehouses in order to encourage "trade and manufacture." Land for the town in lower Norfolk county was to be located "on the Easterne Branch on Elizabeth river at the entrance of the branch." The required land was purchased from Nicholas Wise, a carpenter, for 10,000 lb. of tobacco, and the town was laid out in 1682. In 1705 the house of burgesses made it a port of entry and landing, retaining the name Norfolk, and it was incorporated as a borough in 1736 with Samuel Boush as mayor and Sir John Randolph as recorder.

The commerce of Norfolk for many years depended chiefly on trade with the people of eastern North Carolina, who brought such raw materials as tar, pitch, juniper shingles, plank, hides and tobacco over treacherous waterways or crude roads. As business increased, artisans set up their crafts and shipbuilding and ship repairing became important industries.

Later a brisk trade developed with Barbados and the West Indies; and, as merchant ships became too large to load and unload conveniently at the quays along the rivers and bays, Norfolk became a busy warehouse centre. In recognition of its importance and the loyalty of its citizens, Gov. Robert Dinwiddie in 1753 presented Norfolk with a silver mace still cherished by the city.

The American Revolution brought complete destruction to Norfolk. At first the Norfolk citizens were outspoken against the

Stamp act and Great Britain's "most tyrannick exercise of unlawful power," as one of their protests stated it. But when the royal governor, Lord Dunmore, started open warfare against Virginia and protests ended in bloodshed, much of the population, especially the Scottish merchants, who had close ties with their mother country, made the town a rallying point for Tories.

In Dec. 1775 Governor Dunmore took over Norfolk as his headquarters, declared martial law and defeated a group of Virginia militiamen at Kempsville, southeast of the city. Later in the month Col. William Woodford and his Virginia riflemen completely routed the British at Great Bridge and occupied Norfolk.

On New Year's day of 1776 Dunmore's fleet anchored in the Elizabeth river, bombarded the town and set fire to some of the warehouses. The British burned 19 houses in all. The Virginians under Woodford burned more of the town after the bombardment, and the following month the rest of the town, except for St. Paul's church (which still has one of Lord Dunmore's cannon balls imbedded in its walls), was destroyed to prevent its use by the British.

Although the restoration of Norfolk was surprisingly rapid, the stifling of the West India trade by Great Britain, restrictions on trade and privateering by the French, British and Spanish during the Napoleonic Wars, a disastrous fire in 1799, rivalry of the fall-line cities such as Richmond and lack of an adequate commercial program by the state prevented even more substantial progress.

During the War of 1812 Norfolk was twice saved from invasion by the British. The first time, local militia, reinforced by U.S. marines, beat off a land attack on Portsmouth. An able defense of Craney Island (near the mouth of the Elizabeth) by Gen. Robert B. Taylor prevented the second invasion by barge.

After that war canals and railroads brought improved communications and increased trade with North Carolina and the whole Roanoke river valley. Norfolk continued to grow and in 1845 was incorporated as a city, but yellow fever struck in 1855, killing about 10% of the population, and in 1861 came the Civil War. Shortly after the outbreak of hostilities the navy yard at Portsmouth was burned and the port abandoned by Federal forces. During the next year the Confederates repaired and made good use of the shipyard facilities in the area, among other things, building the "Virginia," first ironclad warship to be tested in battle, from the remains of the Union ship "Merrimack" (*see* "MONITOR" AND "MERRIMACK," BATTLE OF). In May 1862, however, Norfolk fell to Union forces under Gen. John E. Wool and remained an occupied city, part of the time under Gen. Benjamin Franklin Butler (*q.v.*), throughout the remainder of the war.

The progress of Norfolk was accelerated after 1870 because of the completion of railroads converging on the port with its superior facilities. The extension of the Norfolk and Western railroad to the coal fields of Virginia and West Virginia in 1883 started a trade which made Hampton Roads one of the world's greatest coal exporting ports.

During World Wars I and II Norfolk experienced accelerated prosperity, at first caused by heavy shipments to the Allies, and in the later phases of both wars by the activities at the military posts in the area. Correspondingly severe was the postwar deflation following World War I when many of these posts were closed or reduced to skeleton installations. After World War II Norfolk experienced a building boom during which many of the outlying sections of the city were transformed from woods, fields and swamps into urban communities.

Government.—The city of Norfolk, which in 1906 annexed the town of Berkley on the south side of the Elizabeth river, adopted a council-manager form of government in 1918 which controls the city's municipal affairs. The port of Hampton Roads is under the jurisdiction of a state port authority created in 1926. Holdings of the federal government are also extensive in and around Norfolk. The more than 20 major military installations and commands include the naval operating base (Sewell Point), the naval air station (Breezy Point) and the amphibious training base (Little Creek) on the northern edge of the city; the Norfolk naval shipyard and the naval hospital in Portsmouth; and the headquarters of the U.S. Atlantic fleet and the supreme allied command, Atlantic (SACLANT) of the North Atlantic Treaty organization (NATO

Commerce, Industry and Transportation.—Trade in Nor-folk consists mostly of exporting bulk cargoes such as coal, to-bacco, cotton, timber, truck crops and grain. Although it is the Atlantic coast leader in export tonnage and stands high in the value of exports, import tonnage is relatively low. This was ini-tially because of the mountains that stand between Norfolk and the major consumer markets of the eastern and midwestern U.S. thus making inland transportation of goods expensive and causing Norfolk to lose this import trade to ports such as New York and Baltimore, and later to the lack of a thickly settled manufacturing hinterland.

Shipbuilding is perhaps the most important of Norfolk's indus-tries, but the city also produces chemicals, fertilizers, insecticides peanut and cottonseed oil, sea foods, textiles, automobiles, agri-cultural machinery and electric motors.

Norfolk is connected to every port city in Hampton Roads by bridge, tunnel, ferry or, in the case of Hampton, by a combination bridge-tunnel completed in 1957. In 1964 another bridge-tunnel was completed across the entrance of Chesapeake bay to Cape Charles, previously connected to Norfolk only by ferry. The Dis-mal Swamp canal (1828) and the Albemarle and Chesapeake canal (1860), both parts of the Atlantic Intracoastal waterway (q.v. connect Norfolk with Currituck and Albemarle sounds in North Carolina.

Education and Culture.—In addition to excellent public- and parochial-school systems, Norfolk contains Old Dominion college (1930), until 1962 Norfolk college of the College of William and Mary and a division of Virginia State college (1935). Also im-portant in the cultural life of the city are the Norfolk Symphony orchestra and the Norfolk Museum of Arts and Sciences. Places of historical interest include the Myers house (1791), St. Pau church (1739), the Adam Thoroughgood house (*c.* 1636–40) an Ft. Norfolk (1794). The city hall (1850) is now a memorial to Gen. Douglas MacArthur who was interred there in 1964.

Parks and Recreation.—Besides being a busy commercial and industrial city, Norfolk also offers much in the way of recreation: Ocean View, a beach resort area on Chesapeake bay, lies within the city limits and Virginia Beach is only about 18 mi. E. on the Atlantic. The Norfolk Municipal gardens in the northeastern sec-tion of the city contain beautiful displays of azaleas and came-lias. Near the city are also fishing grounds and additional bathing beaches. (R. L. Mo.

NORICUM was in Roman times a district south of the Dan-ube comprising central Austria and parts of Bavaria. As a Roman province its western boundary, against Raetia (*q.v.*), was approxi-mately the Inn river; in the south it met Italy at the summit of the Carnic Alps; and in the east, at least by Tiberius' time the frontier with Pannonia (*q.v.*) was a line running south from a point west of Vindobona (Vienna). But the earlier Celtic king-dom had been larger: on the east it included Carnuntum (q.v. Savaria (Szombathely, Hung.), Poetovio (Ptuj, Yugos.) and Emona (Ljubljana), together with the portion of the tribe of the Taurisci which lived near the source of the Save or Sava river. This kingdom was a Celtic confederacy dominating an earlier Illyrian population. It received Roman protection in the late 2nd century B.C., and had developed a fine culture in the late La Tène period, while Latin legends on coinage and other Latin inscrip-tions attest a marked measure of romanization. Its wealth came from minerals, iron and also gold; Strabo (iv, 208) tells of a Tauriscan gold mine discovered about 140 B.C. which led to an inrush of Romans and a drop in the price of Italian gold by one third.

The kingdom was annexed, apparently as a bloodless conquest by Rome *c.* 15 B.C., and the new province was placed under an equestrian governor, first called a *praefectus* but from Claudius' time a *procurator*. Roman traders and settlers now came in ever greater numbers, and romanization was rapid. Claudius made five of the Norican communities, including the capital, Virunum (near modern Maria Saal in Carinthia), into Roman *municipia*; many Noricans entered the legions; and the province was exceptional in providing soldiers for the praetorian guard, even in the early

century A.D. Crude iron was exported to Italy, especially to Aquileia, but there were also steel manufactures in the province, and Norican swords were familiar to Horace.

After the barbarian invasion of 167 (*see* MARCOMANNI) the frontier was reorganized, and *legio II Italica* was stationed in Noricum, its commander becoming the governor of the province. Its camp, by the end of the 2nd century at any rate, was at Launacum (Lorch, part of modern Enns) Under the later empire Noricum suffered severely from raids by Alamanni and other tribes, and was settled by Franks and Goths before the end of the 5th century.

(G. E. F. C.)

NORILSK, a town in Krasnoyarsk *krai* (territory) of the Russian Soviet Federated Socialist Republic and the most northerly town of the U.S.S.R., lies at the foot of Mt. Shmidtikhi in the Putoran mountains (Gory Putorana), in the valley of the Rybnaya river, between Lakes Melkoye and Pyasino. Pop. (1959) 109,442. Norilsk was founded in 1935 as a mining centre for the rich variety of minerals in the area. Copper, nickel, cobalt, platinum and a little coal are exploited. There are enriching and copper-smelting plants in the town and a thermal power station. A railway links Norilsk to the port of Dudinka on the Yenisei, 72 km. (45 mi.) to the west. (R. A. F.)

NORMAL SCHOOL, an institution for the training of teachers. The first school so named, the École Normale Supérieure (1794), was intended to serve as a model for other teacher-training schools; it later became the College of Pedagogy of the University of Paris. The first public normal school in the United States was established at Lexington, Mass., in 1839 Normal schools were founded chiefly to train elementary-school teachers. They were commonly state supported and offered a two-year course beyond high school. In the 20th century the tendency has been to extend teacher-training requirements to at least four years and, especially after World War II, for the schools to broaden their programs, so that by the 1960s most former normal schools had become colleges or universities.

See TEACHER TRAINING.

NORMAN, MONTAGU COLLET NORMAN, 1ST BARON OF ST. CLERE (1871–1950), British banker, came from a family of merchant bankers with important connections in the United States. He left the family firm and in 1916 joined the Bank of England as assistant to the deputy governor. Norman was himself appointed deputy governor in 1918, and governor in 1920, a post he held for 24 years, longer than any previous governor of the bank. This period was notable for the many grave problems that arose after World War I, when Great Britain's financial ascendancy was first undermined, for the multiplication of the central bank functions in the modern state and for the development of closer relations between the central banks of all countries and in particular between those of Great Britain and the United States. On his retirement in 1944 he was raised to the peerage, taking the title Baron Norman of St. Clere in the county of Kent. He died on Feb. 4, 1950.

See Sir Henry Clay, *Lord Norman* (1957). (GA. S.)

NORMAN, a city in central Oklahoma, U.S., 18 mi. S. of Oklahoma City, is located on a plateau overlooking the valley of the South Canadian river; the seat of Cleveland county. Norman is the marketing and distribution centre of an extensive agricultural area which produces livestock and dairy products. There are also oil wells in the vicinity and some light industry.

Beginning as a tent city in April 1889, when Oklahoma was opened to white settlement, Norman was named in honour of an engineer who, in the 1870s, had aided in constructing the Santa Fe railroad through the territory. Before the settlement the railroad called the site Norman Switch. Incorporated in 1902, Norman adopted a commission-manager form of government in 1919.

The University of Oklahoma (*see* OKLAHOMA: *Education*), with 12 schools and colleges, was established there in 1892 on land donated by the people of Norman. The city is also the site of a state mental hospital and a cerebral palsy institute. For comparative population figures *see* table in OKLAHOMA: *Population*. (GE. H. S.)

NORMANDY, an ancient province of northern France. Its boundaries were approximately as follows: west and north, the English channel; northeast, the Bresle river, separating Normandy from Picardy; east, the Epte river, separating the Vexin Normand from the Vexin Français; southeast, a border between the Seine-Epte confluence and the Eure-Avre confluence, separating Normandy from the westernmost appendage of the government of the Île-de-France and from Orléanais; south, the Avre and upper Sarthe rivers as far as Alençon, separating Normandy from eastern Maine; and southwest, the Collines de Normandie and the lower Couesnon river, separating Normandy from western Maine and from Brittany. It thus corresponds, in terms of modern *départements*, to Manche, Calvados, Seine-Maritime and Eure (*qq.v.*), with Orne (*q.v.*) apart from Mortagne and Domfront. The provincial capital was Rouen (*q.v.*).

Ancient History.—The Seine and Eure valleys were inhabited in paleolithic times. The Cotentin peninsula and its hinterland have megalithic monuments like those of Brittany. Prehistoric metallurgy was affected by contact with the British Isles. Conquered by the Romans in 56 B.C. the future Normandy was organized in the 4th century A.D. as the province of Gallia Lugdunensis II.

Some Germanic settlement on the coast was begun before the collapse of the western Roman empire. On the overthrow of the kingdom of Syagrius in 486 the country passed under Merovingian Frankish rule. The Franks did little to modify the administrative structure, but promoted the foundation of great abbeys (St. Wandrille, Jumièges, Fécamp, Mont-St.-Michel). In the Merovingian partitions of France, the country was included in Neustria (*q.v.*), a name later taken sometimes to mean Normandy in particular.

The Norman Dynasty.—The Vikings (*q.v.*), Northmen or Normans were raiding the coast in Charlemagne's time; and as the Carolingian kings became weaker the invaders penetrated farther inland. Finally the French king Charles III the Simple (*q.v.*) came to terms with Rollo, the chief or duke of the largest band of Normans, accepting him as his vassal for part of the territory. This transaction (autumn 911?), known as the treaty of St. Clair-sur-Epte, is recorded only by the strongly pro-Norman Dudo (*q.v.*), writing nearly 100 years later. It seems that Rollo was originally enfiefed with lands in the dioceses of Rouen, Lisieux and Evreux. Subsequently, however, Rollo obtained rights over the Bessin (the country round Bayeux, where there had been a settlement of Normans independent of him) on transferring his allegiance to the Robertian king Rudolph (Raoul) in 923.

Rollo was baptized in 912, but is said to have died a pagan (927, 932 or 933?). His son William I Longsword was steadfastly Christian. William did homage to King Rudolph in 933 for the Cotentin and Avranches, where the local Normans had been regarded as more or less dependent on Brittany; and after Rudolph's death he came to terms with King Louis IV, of the restored Carolingian dynasty. In 942 he was assassinated.

William's young son and successor Richard I was taken into protective custody by Louis IV. Campaigning to bring the Normans under control and perhaps to reunite the fief to the crown's domains, Louis was in 945 taken prisoner by the Normans (who had been reinforced from Scandinavia or Denmark) and was handed over by them to the Robertian Hugh the Great, whom he had tried to entangle in his enterprise. Returned to his people, Richard withstood the last Carolingian attempts to subdue the duchy and, in 987, was instrumental in securing the French crown for the Robertian Hugh Capet, his brother-in-law.

Richard II, who succeeded his father Richard I in 996, held his own against a peasant insurrection, helped Robert II of France against the duchy of Burgundy, repelled an English attack on the Cotentin and conducted a war against Eudes, count of Chartres, against whom he asked for Danish help. On his death (1026 or 1027), his sons Richard III and Robert I (*see* ROBERT, dukes of Normandy) disputed the succession till the former's opportune death a year or two later. Robert I, known to legend as Robert

the Devil, obtained the Vexin Français from Henry I of France, whose side he took in the troubles following his accession. He died on his way home from a pilgrimage to Jerusalem in 1035.

Robert was succeeded by his bastard child William II (*see* WILLIAM I, king of England). Henry I of France took advantage of the situation to recover the Vexin Français, but supported William when the barons of the Bessin and the Cotentin rebelled, so that the rising was defeated in the battle of Val-aux-Dunes, near Caen, in 1047. In the 1050s, however, when William formed his alliance by marriage with Flanders, Henry turned against him. A French invasion from Picardy was defeated by the Normans at Mortemer in 1054 and a joint French and Angevin invasion at Varaville in 1058.

While the dukes had been consolidating their power for the past 150 years, the growth of the Norman population had outstripped the expansion of their territory. This explains the major role taken by sons of the Norman baronial houses in enterprises abroad: especially in the expeditions which led to the foundation of the Norman kingdom of Sicily. Comparable to the last-named achievement, but of far greater importance to Normandy itself, was Duke William's own conquest of England, from 1066.

During William the Conqueror's absences in England, Normandy was under the regency of his consort, Matilda of Flanders, with whom their eldest son Robert Curthose or Courteheuse (*see* again ROBERT) was associated from 1067 except when he was in rebellion against his father. Philip I of France, alarmed at his Norman vassal's excess of power, did what he could to weaken the duchy by favouring rebellion and invasion; and William died on an expedition for the recovery of the Vexin Français (1087). The personal union of Normandy and England was then broken: Curthose became duke as Robert II, but England passed to his next surviving brother, king as William II. The brothers, however, were not long at peace: Robert, as the more convenient vassal, had Philip's support; and William II was finally helped by his other brother Henry. On William II's death (1100) Robert's designs on England were frustrated by this other brother who became king as Henry I (*q.v.*). Fraternal quarrels continued, despite negotiation; and in 1106 Henry defeated Robert in the battle of Tinchebrai and became duke of Normandy himself. Louis VI of France took up the cause of Robert's son William the Clito against the revived Anglo-Norman power. Henry I, however, had his own only son William the Aetheling recognized as heir to Normandy and, in 1119, decisively defeated Louis VI and William the Clito at Brémule, in the Vexin Normand. When the Aetheling was drowned (1120), the Clito made further trouble in Normandy, but he died in 1128.

The Angevins and the French Conquest.—With Henry I's death (1135) the male line of the house of Rollo came to an end, and the Norman succession was long disputed. In 1144, however, Geoffrey Plantagenet, count of Anjou, second husband of Henry I's daughter Matilda (*q.v.*), finally won Normandy from the rival house of Blois. He and Matilda ceded the duchy to their son Henry in 1150. Having inherited Anjou and Maine from his father (1151) and acquired Aquitaine by marriage (1152), the duke became king of England as Henry II (*q.v.*) in 1154.

Efficiently divided for administrative purposes into viscounties under men who were originally the duke's vassals for their office but not for the territory that they administered (*baillis* were later appointed to supervise groups of viscounties), Normandy became a model state. It was also the geographic centre of the so-called Angevin empire. It was thus a primary objective for the Capetian kings of France in their struggle against the Plantagenet Angevins of England.

Louis VII of France, who had obtained the Vexin Normand as his price for recognizing the Angevin accession to Normandy, went to war with Henry on the latter's Aquitanian marriage, but later, by the treaty of Gisors (1158), agreed that Gisors and the Vexin Normand should be the dowry of his infant daughter Margaret, who was to marry Henry's eldest son Henry, later known as the Young King. Later intermittent warfare between Louis VII and Henry ended with the treaty of Montlouis (1174); but Philip II Augustus (*q.v.*) resumed the struggle. In 1187 he began by demanding the surrender of the Vexin, on the ground that Henry the Young King had died in 1183 and that the newly projected marriage of the latter's brother Richard (*see* RICHARD I, king of England) to the French princess Alice, who would have had the same dowry as Margaret, had not taken place. Philip supported Richard in the rebellion that hastened Henry II's death, and Richard was crowned duke of Normandy at Rouen in July 1189, before his English coronation.

The treaty of Messina (1191), which Philip and Richard concluded in Sicily on their way to the crusade, did not terminate the question of Gisors and the Vexin, which Philip consequently tried to annex, with the connivance of Richard's brother John (*see* JOHN, king of England), during Richard's captivity in Germany. On his return Richard won a great victory over Philip at Fréteval near Vendôme, in July 1194; but at the end of 1195 he concluded the treaty of Louviers, renouncing the Vexin Normand. He then began the rapid construction of the great stronghold of Château-Gaillard (*q.v.*), enclaved within the Vexin. When Philip had renewed hostilities in 1198, Richard won another victory at Courcelles in September; and by the treaty of Jan. 1199 the only Norman place left to Philip was Gisors. Three months later Richard was dead.

Though John secured the Norman and the English crowns (April–May 1199), his nephew Arthur of Brittany was put forward for the succession by a strong party in the other Angevin territories. Philip favoured Arthur till, by the treaty of Le Goulet (May 1200), he obtained from John not only the Vexin Normand but also the countship of Evreux, as well as concessions not affecting Normandy. Less than two years later, however, John was declared to have forfeited all his French fiefs; and in summer 1203 Philip invaded Normandy. Château-Gaillard, which John had retained, fell after a long siege; and when Rouen capitulated in June 1204 all Normandy was Philip's. Yet it was only with the treaty of Paris (1259) that the English crown specifically acknowledged the loss of Normandy to France.

Normandy and the Capetians.—Already under the Angevins there were communes in Normandy (*see* COMMUNE [MEDIEVAL]) and in 1204, when he entered Rouen, Philip Augustus had to guarantee the town's charter, the so-called *Établissements* (dating from *c.* 1170). Throughout the 13th century the arbitrary levying of services and taxes by the French kings was resented. To conciliate opinion Philip IV and Louis X issued the two ordinances together known as the *Charte aux Normands* (1314–15), guaranteeing a number of privileges to the duchy: there was to be no extraordinary taxation "save in absolute necessity"; vassals were not to be forced to do military service beyond the normal term due; freemen were not to be put to the torture save in grave presumption of a capital crime; and the Norman exchequer (a court of justice as well as a financial bureau) was to have cognizance of all cases arising within the duchy, without any evocation to the Paris parlement.

The Hundred Years' War.—In the first phase of the Hundred Years' War (*q.v.*) one of the Norman barons, Godefroy d'Harcourt, was already conspiring in 1343 against Philip VI of France and his son John (the future John II of France, on whom the duchy had been bestowed) before Edward III of England landed in the Cotentin in 1346. Subsequently the French position in Normandy was weakened by the fact that the malevolent Charles II (*q.v.*) of Navarre held lands there; but though the draft treaty of London (1359) stipulated cession to England, the treaty of Brétigny (1360) left Normandy to France.

Charles V, whom John had made duke of Normandy in 1355, began his reign as king of France by sending Bertrand du Guesclin to defeat the Navarrese at Cocherel on the Eure (1364); but in the Cotentin the English and the Navarrese long held their ground. French taxation led to the revolt of the Harelle in Rouen (1381–82).

The English king Henry V's victorious campaigns began with his capture of Harfleur in Sept. 1415; and by 1420 all Normandy except Mont-St.-Michel was in English hands. Though the English established a council for Normandy and emphasized the duchy's separateness from France (*cf.* the foundation of the University of Caen by Henry VI in 1432), there was always some resistance

to their regime; and after the death of the capable governor, John, duke of Bedford, this resistance gathered strength: the Pays-de-Caux rose in 1435, the Val-de-Vire in 1436. The French reconquest, however, was postponed till 1449. After the battle of Formigny (*q.v.*), in 1450, the last English strongholds surrendered.

The French Province.—Louis XI of France gave the duchy of Normandy to his brother Charles in 1465 but soon took it back and finally persuaded the French estates-general at Tours in 1468 to declare Normandy inalienable from the French crown. Thereafter Normandy was governed as a province, though for some time the *Charte aux Normands* was theoretically maintained. The exchequer became a *parlement*, with its seat permanently at Rouen. Norman participation in overseas exploration and trade from the start of the 16th century revived the maritime tradition.

Protestantism made great headway in Normandy, especially at the University of Caen. There was bitter fighting between Catholics and Huguenots in the periods 1561–63 and 1574–76 before the final contest between King Henry IV and the Holy League. Despite Henry's victories at Arques (1589) and at Ivry (1590), Rouen, with occasional relief from the Spanish Netherlands, held out for the League till March 1594.

Oppressive taxation during the Thirty Years' War provoked the rising of the *Va-nu-pieds* ("Barefeet") in 1639, which was ruthlessly put down. The attempt of the governor, Henry duc de Longueville, to rally Normandy to the Fronde in 1649 was a fiasco.

Louis XIV's intendants worked to assimilate Normandy's institutions to those of France and to promote still further its commerce and its maritime activity. The revocation of the Edict of Nantes (1685) led to a mass emigration of Huguenots, who had contributed greatly both to the economy and to the navy; but even so Normandy soon recovered its prosperity in the 18th century. The *départements* into which Normandy was dissolved in 1790 generally took a "federalist" attitude during the French Revolution, and the western areas were favourable to the Chouans (*q.v.*).

For the Normandy landings and the campaign of the Allies in 1944 *see* World War II. *See* also references under "Normandy" in the Index.

NORMANS, originally *Nortmanni* (Northmen), the term used generally in western Europe to denote the barbarian heathen pirates from Scandinavian lands, especially Denmark, Norway and, later, Iceland, who began to make destructive plundering raids on the west in the 8th century (*see* Viking). In the form "Normans" the term refers particularly to those Vikings who settled in northern *Francia* (the Frankish kingdom) and to their descendants, who together founded what became the duchy of Normandy and sent out fresh expeditions of conquest and colonization to southern Italy and Sicily, to England, Wales, Scotland and Ireland. The Normans did not themselves mark out the boundary of the territory they won in France: it was approximately the ancient ecclesiastical province of Rouen, itself in turn based on the Gallo-Roman province of Lugdunensis Secunda. But from an early period this territory acquired the name *Nortmannia* (Normandy) and this fact, together with the settlers' adoption of Christianity and the speech and culture of the Franks, shows that the people of Normandy must be regarded as historically distinct from, though clearly related to, the other pirate colonists of Scandinavian stock, whether in Britain, Ireland, the Loire valley or elsewhere.

Origins and Character.—During the second half of the 9th century, Viking raids on the northern and western coast lands of France had been growing in scale and frequency. In the last decades of the century a number of Scandinavians, of whom the majority were probably Danes, had secured a permanent foothold on Frankish soil in the valley of the lower Seine. In an unknown year during the first decade of the 10th century, a Viking named Hrólfr (Rollo), nicknamed the Ganger ("walker"), who had already gained a reputation as a great leader of Norse raiders in Scotland and Ireland, came to the Seine and soon emerged as the outstanding personality among the heathen settlers. Rollo was probably a Norwegian, the son of Rögnvald, earl of Möre (the district of Romsdal in western Norway). He had certainly achieved a leading position among the Seine Vikings by 911 when, as a result of the battle of Chartres, the Frankish king Charles III the Simple made the so-called Treaty of St. Clair-sur-Epte with the Vikings, allowing them to occupy the land between the Epte and the sea stretching from the Dives river on the west to the Bresle river on the east. It may be assumed that this Frankish concession was conditional on the Vikings' accepting Christianity and performing military service for the Carolingian monarchy. Within a generation (933) the Norsemen, still largely heathen in religion and piratical in behaviour, had extended their rule westward to Mont-St.-Michel, wresting from the Bretons the districts of Lower Normandy—the Bessin, Avranchin, Cotentin and Coutances. From 933 to the victory of William the Bastard at Val-ès-Dunes in 1047, the history of the Normans in Normandy (*q.v.*) was dominated by the struggle of a line of ruthless and forceful rulers, calling themselves variously counts of Rouen or Normandy and counts or dukes of the Normans, to establish political hegemony over the Frankish population of Upper and Lower Normandy and over their Scandinavian ruling class. In this struggle the two halves of Normandy were, not without difficulty, welded together, and the racial personality of the Normans was evolved.

Despite their permanent settlement in Gaul, their conversion to Christianity, their adoption of the French language, and their abandonment of sea-roving for Frankish cavalry warfare, the Normans retained many traits of their Viking ancestors. They displayed an extreme restlessness and recklessness, an unquenchable greed for wealth and power, a love of fighting accompanied by courage that was often foolhardy, and a craftiness and cunning which frequently went hand in hand with outrageous treachery. A reader of the sagas who turns to the chronicles that narrate the deeds of the Normans in Normandy, Britain or southern Italy cannot fail to be struck at many points by the close similarities between the Norsemen proper and their half-gallicized kinsmen: the astonishing daring of exploits by which, time and again, a mere handful of men would vanquish an enemy many times as numerous, the unequaled capacity for rapid movement across land and sea, the brutal, sacrilegious violence, the fondness for vivid and often unflattering nicknames, the precocious sense of the use and value of money—all these things were equally true of Norsemen and Normans. The conquest of Ulster by John de Courci (*q.v.*) might easily, for instance, in almost every detail, form the theme of a saga telling of some heroic Viking enterprise. In the same way, the part played by Bohemund I (*q.v.*) in the first crusade at once recalls the irresponsible bravery and cunning of a Viking freebooter.

Among the Norman traits regarded by contemporaries as specially characteristic, perhaps the most significant for history were their utterly unbridled character (*effrenatissima gens*, in the phrase of Geoffrey Malaterra, the 11th-century author of the *Historia Sicula*, [*The Sicilian History*]) and the capacity for quick and fruitful imitation and adaptation. The former was historically important because it meant that wherever a Norman state survived at all, as in Normandy itself, England or Sicily, it threw up, by a process akin to natural selection, a line of outstandingly able and ruthless rulers. William Longsword (d. 942), Richard II (d. 1027), Robert (*q.v.*) the Devil and William the Bastard, counts or dukes of Normandy; the last named (*see* William I) and his two sons, William II Rufus and Henry I, kings of England; Robert (*q.v.*) Guiscard (from Hauteville in Lower Normandy), his brother Roger I and nephew Roger II (*qq.v.*), rulers of Apulia and Sicily, were all among the most powerful and successful secular potentates of their age in western Europe. Provided that men of this calibre had good material to work upon, as they undoubtedly had in England and Sicily, they were able to create political institutions which proved stable and enduring (*see* English History: *The Normans*; Sicily: *History*).

The Norman Role in European History.—The Normans began as pagan destroyers, bent upon almost senseless plundering and slaughter. Forced to come to terms with the Carolingian and Capetian dynasties, to adopt French as their own language and Christianity as their religion, they quickly became missionaries and proselytizers of the civilization which they had attacked and which had ultimately absorbed them. They early grasped the principles

of Carolingian feudalism (*q.v.*), and Normandy became in the 11th century one of the most highly feudalized states in western Europe. Although the duke's own *servitium debitum* performed to the king of France was a mere ten knights, he himself could count on the service of hundreds of mailed knights, many of whom fought under the banner of the great Norman feudatories.

The art of castle-building was not a Norman invention, but the Normans became masters in the use of the simple yet enormously effective motte-and-bailey castle—a mound (motte) topped by a timber palisade and tower, surrounded by a ditched and palisaded enclosure (bailey). These little fortifications, which were complementary to the warfare conducted in open country by small units of cavalry, became the hallmark of Norman penetration and conquest. Again, although the Normans were at first learners and imitators in the practice of fighting on horseback, they took to cavalry warfare as to the manner born. Mounted on much the same breed of *destrier* or war horse as his Frankish, Angevin or Breton opponent, wearing the heavy mail *hauberk* or *byrnie* that was general among the warriors of northwestern Europe, protected by a conical helmet with long nasal, and by the familiar kite-shaped shield, armed with a long, broad-bladed sword and a slender lance, the Norman horse soldier of the 11th and 12th centuries proved on countless occasions that he could outfight and overwhelm the most powerful forces brought against him. To some extent, no doubt, this was due to the great importance which the Norman knightly class attached to the training of young warriors. They eagerly adopted the carefully fostered cult of knighthood, to some extent Christian in inspiration and based upon the belief that there should be in society an order of warriors dedicated to the art of cavalry warfare, which had grown up in the northwestern portion of the old Carolingian empire in the 10th and 11th centuries. But in the 11th century, when the Normans won their reputation, the Christian qualities in knighthood were almost negligible. The Norman knights were fierce and brutal mounted soldiers who had received an arduous training that left little room for the feelings of humanity and mercy with which Christian teaching was later to endow the concept of chivalry. To find a parallel it would be necessary to cite their terrible kinsmen, the Jomsborg Vikings, or even, still farther afield, the Seljuk Turks, barbaric mounted warriors whose role in Islam was curiously similar to that of the Normans in Christendom.

Just as the Normans became the typical exponents of Carolingian feudalism and of cavalry and castle warfare, so they also, though in a narrower sense, became the exponents and champions of religious orthodoxy. The conversion of the Scandinavians of Normandy was a slow and gradual process. Even by the end of the 11th century the Norman episcopate had barely accomplished the task of restoring one of the most desolated provinces of the western church. But under the patronage of the ducal house religious life flourished and a number of Norman monasteries, notably Bec, Fécamp, St. Evroul and St. Stephen's, Caen, became renowned centres of Benedictine life and learning. This was chiefly due to the encouragement given to non-Norman scholars and reformers, such as the Italians William of Dijon, Lanfranc of Pavia and St. Anselm of Aosta, to make their home in Normandy.

The great religious and ecclesiastical revival which marks 11th-century Normandy found another expression in the enormous popularity among the Normans of pilgrimages to Rome and the Holy land. This yearning for pilgrimages was one of the factors responsible for the Norman conquest of southern Italy (*c.* 1030–71) and of Sicily (1060–91). The other main factor was the emergence in the first half of the 11th century of what was virtually a new aristocracy in Normandy. In the struggles that accompanied this profoundly important social movement, and especially during the long minority (1035–47) of William the Bastard, many Norman nobles, and some younger sons with few prospects of inheritance at home, journeyed to the Mediterranean, inspired by a naïve mixture of religious devotion, love of adventure and desire for fresh conquests. In the south, once they had transformed themselves from casual bands of mercenaries and freebooters into the ruling class of a mixed Lombard, Byzantine and Saracenic state, the Normans stood for championship of the reformed and reforming papacy. In this situation there was an irony highly characteristic of the Normans, for their role as protectors of the Holy See and of orthodoxy was founded on the battle of Civitate, 1053, in which they inflicted a crushing defeat on a papal army under Leo IX, and on the terrible sack of Rome which they carried out ostensibly on behalf of Pope Gregory VII, in 1084. Surprisingly the part played by the Normans in the early crusades was relatively slight, consisting chiefly of the typically selfish and aggressive erection of the short-lived principality of Antioch by Robert Guiscard's eldest son Bohemund and his nephew Tancred. The role of the Normans in Europe in the 11th and 12th centuries may be summed up by saying that by their fierce energy and enterprise they extended the practice of centralized authoritarian rule, feudalism and cavalry warfare, and that through their simple devotion to the papacy they helped to spread the ideas of the reform movement in the western church.

Adaptation of Institutions in Sicily and the British Isles. —Geoffrey Malaterra said that the Normans were quick to imitate whatever they saw, and this faculty of imitation is evident in all the different countries where the Normans settled. But Norman imitation was never slavish, and is certainly not the whole story of Norman achievement. A truer explanation of Norman success would be that they combined a boundless self-confidence with a wonderful capacity for adapting to their own purposes the institutions they found in newly won territories. Thus, in Apulia and Sicily their control was based on faith in their own military superiority, in their strategic use of castles and harbours, and in their importation of feudalism to govern the relations of the count or king with his greater subjects. But in government they adopted the highly advanced and largely literate techniques already developed by the Greeks and Saracens. Though champions of the papacy, they preserved the existing tradition of religious toleration, which was accompanied by complete racial toleration. Without this toleration the Norman kingdom of Sicily would not have been possible. It was inevitable that the distinctively Norman character of Sicily should vanish during the 12th century, as the stream of Norman migration dried up, yet under the two Rogers and the two Williams it was, undeniably, a Norman vigour and attention to detail and a Norman concern for the strength of the royal financial system which made Sicily one of the richest and most powerful states of the Mediterranean.

North of the English channel, the Normans similarly brought their own brand of feudalism and their own ideas of strong personal government and fiscal institutions. But as in Sicily they adopted many existing native institutions and customs. In England even at the end (1135) of Henry I's reign the whole structure of royal government remained fundamentally Anglo-Saxon—monarchy, king's council, royal seal and writing office, the shire system and the sheriffs, the twofold revenue system consisting of the produce of royal estates compounded into annual cash payments, and a direct tax or geld levied on the landowning class, all originated from before the Conquest. But under Norman direction, and with a number of Norman innovations such as the exchequer, the itinerant justices and the sworn inquest (*see* ENGLISH LAW: *The Norman Age*), this system worked much more efficiently after 1066 than before, and, a fact of equal importance, England was made safe from foreign invasion. Norman influence on the church in England also worked powerfully in the direction of better organization and discipline.

In Scotland, after the accession of David I (*q.v.*) in 1124, the Normans penetrated in significant though never large numbers. They were encouraged by the ruling house and in consequence, though one can hardly speak of a Norman conquest of Scotland in the accepted sense, the Scottish kingdom by the late 12th century was thoroughly normanized in many features, notably military feudalism and methods of royal government. Here adaptation was of Celtic rather than Anglo-Saxon institutions, and the contrast between Scottish earldoms, to many of which men of Norman descent succeeded, and the English earldoms, which William I restricted and his successors turned into virtually honorific titles, remained striking as late as the 13th century. An earldom in Scotland remained an integral element in the administrative and

tary structure of the feudal kingdom. In Wales and Ireland, where the Normans settled at first in very small numbers, the degree of adaptation to native conditions was perhaps more marked than anywhere else. In Wales Norman lords acquired Welsh principalities and lordships intact and adopted many Welsh customs, including even the right of private war and a fixed share of booty captured from enemies. At the same time, they introduced towns and castles. The Normans in Ireland behaved in much the same way, though at first they were subject to a more stringent control by the English crown, which for a century maintained an efficient government at Dublin. Many Norman families in Ireland, however, as in Scotland, became thoroughly merged with the native population.

Summary.—The Normans had many shortcomings. Few intellectuals of eminence in the 11th or 12th centuries, still fewer spiritual leaders, were of pure Norman stock. Norman literature is negligible beside English or French. In the graphic arts little identifiably Norman work is outstanding. Norman architecture, impressively massive and enduring as it can be at its best, was a not specially original variant of the Romanesque of northern Europe. Nevertheless, they produced numerous leaders who worked for order and respect for the law in an age when barbarity and anarchy were still prevalent, and, in Sir Frank Stenton's phrase, "politically, they were masters of their world." *See* also references under "Normans" in the Index.

NORMAN STYLE, in architecture, the Romanesque style developed in Normandy and England during the 11th and 12th centuries, up to the time of the general adoption of Gothic architecture in both countries. Since it was only shortly before the Norman conquest of England that Normandy became settled and civilized enough to produce an architecture, the origin in both countries is the same, and early types are extremely similar. This common early Norman differed from Romanesque in its love of geometric ornament such as zigzags, general crudeness in the scant figure and leaf carving, and a daring originality in construction ideas, possibly owing much to the fact that Lanfranc of Pavia (d. 1089) had introduced Lombard ideas into many Norman abbeys.

Although the English and French phases of the style were thus identical at the start, they soon became different. The French was characterized by careful structural articulation (Abbaye-aux-Dames and Abbaye-aux-Hommes, Caen, both founded in 1062 but altered later) and elaboration of tower and spire (St. Michel de Vaucelles, Caen, 12th century).

In England the chief characteristics are enormous length of church plan, the frequent use of great round columns for the nave arcade (Gloucester cathedral, 1089–1100; Tewkesbury abbey, 1123; and Durham cathedral, alternate piers, 1099–1128) and great decorative richness (Prior's door, Ely cathedral, late 12th century; St. Mary's chapel, Glastonbury abbey, 1186; the front of Iffley church, 12th century; and the Galilee porch at Durham, c. 1175). The general Norman structural genius is most markedly shown in the buttressing system and in the ribbed vault of Durham cathedral, whose date is much debated, being placed as early as 1133 and as late as the 13th century. *See* ROMANESQUE ARCHITECTURE; GOTHIC ARCHITECTURE; *see* also references under "Norman Style" in the Index.

NORNS correspond in Germanic belief to the *Moirai* (*see* FATE, in Greek; the name is found only in Scandinavian sources. They are usually represented as three and as spinning or weaving the fate of men. Some sources name them Urðr, Verðandi and Skuld, perhaps meaning roughly Past, Present and Future. In consequence of their presence at births, midwifery is sometimes associated with them. They are represented as dwelling by the "world tree," Yggdrasil's ash; and thus may also have been regarded as dispensers of blessing and fertility. (K. C. K.)

NORRBOTTEN, the northernmost and largest *län* (county) of Sweden, lies between the Gulf of Bothnia, Finland and Norway. Pop. (1960) 261,672; area 40,879 sq.mi. It extends for about 135 mi. from east to west, and for about the same distance from south to north, projecting into Lapland and the Arctic circle. From the coast, the land rises to the barren mountainous frontier with Norway, and there ancient rocks are exposed. In this district is the highest land in Sweden (Kebnekaise, 6,965 ft.), unexplored until 1880. The upland is crossed by depressions and that of Torneträsk allows a route to ice-free Narvik (*q.v.*), permitting winter export from the five iron-mining centres around Kiruna. A number of large, long lakes in these depressions help to regulate the river flow. Railways extend in the coastal zone through Boden to the frontier town of Haparanda (connecting with the different gauge of Finland) and inland through the Lapp centre of Jokkmokk. The region was occupied late by Swedish settlers but now has considerable significance through its mineral wealth. Few crops can mature in the short summer and timber is slow growing. The Lule river (Lilla Luleäv) has been harnessed at Porjus for power, which supplies the Narvik railway and industrial centres in the south. At Porjus and Luleå (*q.v.;* the county town) there is electrical smelting of iron. (A. C. O'D.)

NORRIS, FRANK (BENJAMIN FRANKLIN NORRIS) (1870–1902), U.S. novelist of the naturalistic school, was born in Chicago, Ill., March 5, 1870. He studied art in Paris and attended the University of California, Berkeley, and Harvard. He was news correspondent in south Africa, 1895; editorial assistant on the *San Francisco Wave*, 1896–97; and war correspondent in Cuba for *McClure's Magazine*, 1898.

Norris' *McTeague* (1899) is a tragedy of mean streets in San Francisco. *The Octopus* (1901), first of a projected trilogy, *The Epic of the Wheat*, pictures with bold symbolism the growth of the wheat in California and the struggle of the ranchers with the railway corporation. *The Pit* (1903) deals with wheat speculation on the Chicago board of trade, and *The Wolf*, unwritten at his death, would have shown the wheat relieving an old-world famine. *Vandover and the Brute* (1914) is a memorable study of degeneration.

After the example of Zola and the naturalists, Norris emphasized the determinism of heredity and environment in human life. Early influenced by Kipling and by popular notions of evolution, he exalted primitivism, but he finally adopted a more humanitarian ideal and began to view the novel as a proper agent for social betterment. He thus gave an impulse to the "muckraking" movement which followed, though he disavowed overt propaganda in the novel (*see* MUCKRAKERS). He strove to return American fiction, then dominated by historical romance, to more serious themes. Despite philosophic inconsistencies and romantic intrusions in his work, Norris was a writer of great original force. He died in San Francisco, Oct. 25, 1902.

Among his other works are: *Moran of the Lady Letty* (1898), *Blix* (1899), *A Man's Woman* (1900) and *The Responsibilities of the Novelist* (1903). His writings were collected (10 vol.) in 1928, and *The Letters of Frank Norris* edited by F. Walker in 1956.

BIBLIOGRAPHY.—Franklin Walker, *Frank Norris* (1932); Ernest Marchand, *Frank Norris: a Study* (1942); Maxwell Geismar, *Rebels and Ancestors*, with bibliography (1953). (E. MD.)

NORRIS, GEORGE WILLIAM (1861–1944), U.S. senator from Nebraska noted for his advocacy of many political reforms and of public ownership of hydroelectric power plants, was born on a farm in Sandusky county, O., on July 11, 1861. The death of his father and of his only brother left the family in straitened circumstances. At an early age Norris became the chief support of the farm household and was able to attend school only in the winter. Largely self-educated, he taught school and studied law at Northern Indiana Normal school (now Valparaiso university). He was admitted to the bar in 1883 and two years later moved to

Nebraska to begin practice. He was soon elected prosecuting attorney of Furnas county and in 1895 became district judge of the 14th judicial district, serving until 1902 when he successfully ran for congress as a Republican. He was re-elected for five successive terms, becoming leader of an insurgent group which in 1910 forced reforms in the house rules to reduce the autocratic control of the speaker.

In 1912 Norris was elected to the senate, where he served until 1943. As a senator he became known as an independent who, in his own words, "would rather be right than regular." His strong antiwar convictions led him to vote against the entry of the United States into World War I, and he denounced the Versailles treaty that followed it. He fought for many political reforms, such as presidential primaries and the direct election of U.S. senators. Norris was the author of the 20th amendment to the constitution which abolished the so-called "lame duck" sessions of congress. He introduced bills for the retention of Muscle Shoals as a government power-development project and for establishing the Tennessee Valley authority. The first TVA dam, completed in 1936, was named in his honour. He was also a leader in the demand for farm relief legislation and coauthor of the Norris-LaGuardia act, which restricted the use of injunctions in labour disputes and opened the way for a changed legal concept of labour-management relations.

Though always a Republican, Norris felt his party ties lightly; he endorsed Theodore Roosevelt in 1912, La Follette in 1924, Smith in 1928 and Franklin D. Roosevelt in 1932, 1936, 1940 and 1944. Norris spent a half century in public life, 40 years of it in congress. His last fight was an unsuccessful attempt to pass legislation outlawing the poll tax. He died Sept. 2, 1944, in McCook, Neb. In 1945 his book *Fighting Liberal* was published.

See Richard Lowitt, *George W. Norris: the Making of a Progressive, 1861–1912* (1963); Norman L. Zucker, *George W. Norris: Gentle Knight of American Democracy* (1966). (R. B. N.)

NORRIS, JOHN (1657–1711), English philosopher, notable both as a continuator of Cambridge Platonism and as an exponent of the theories of Nicolas Malebranche, was born at Collingbourne-Kingston in Wiltshire. Educated at Winchester and at Exeter college, Oxford, he became a fellow of All Soul's college in 1680. In 1689 he was appointed to the living of Newton St. Loe in Somerset. Thence in 1691 he was transferred to the rectory of Bemerton in Wiltshire, where he spent the remainder of his life. His numerous publications include poems and translations; moral and mystical writings; and theological and philosophical works, as well as a political tract, *A Murnival of Knaves, or Whiggism Planely Displayed and Laughed out of Countenance* (1683).

The poems (chiefly represented in his *Collection of Miscellanies*, 1687; *cf.* A. B. Grosart (ed.), *The Poems of John Norris*, 1871) and the translations must be ranked as minor works. The mystical and moral writings are those in which Norris shows most clearly the influence of the Cambridge Platonists, in particular that of Henry More and of Ralph Cudworth. In *An Idea of Happiness* (1683), following Plato, he places the soul's highest happiness in the contemplative love of God. *The Theory and Regulation of Love* appeared in 1688, with Norris' correspondence with More as an appendix. Other publications of this group were *Reflections upon the Conduct of Human Life* (1690), in the form of a letter to Lady Masham; *Christian Blessedness, or Discourses upon the Beatitudes* (1690); *Practical Discourses on Several Divine Subjects*, 3 vol. (1691–93); and *Letters Concerning the Love of God* (1695), being his correspondence with Mary Astell.

Norris' first considerable philosophical work was *Reflections upon a Late Essay Concerning the Human Understanding*, appended to the first edition of *Christian Blessedness;* in this he anticipated many later criticisms of Locke's theory, though he agreed with Locke in dismissing the doctrine of innate ideas. His adoption of Malebranche's theory of divine illumination involved him in controversy with the Quakers, against whose notion of "the Light within" he published *Two Treatises Concerning the Divine Light* (1692). His *Account of Reason and Faith* (1697) is one of the best of the many answers to John Toland's *Christianity Not Mysterious:* reason, according to Norris, is nothing but the exact measure of truth, that is to say, divine reason, which differs from human reason only in degree, not in nature. His most important work, *An Essay Towards the Theory of the Ideal or Intelligible World*, appeared in two parts (1701–04): the first treats the intelligible world absolutely; the second considers it in relation to human understanding. This work is a complete exposition of the system of Malebranche, in which Norris refutes the assertions of Locke and the sensualists. In *A Philosophical Discourse Concerning the Natural Immortality of the Soul* (1708) Norris defends that doctrine against Henry Dodwell.

NORRISTOWN, a borough of southeastern Pennsylvania, U.S., is located on the north bank of the Schuylkill river, about 18 mi. N.W. of Philadelphia, the seat of Montgomery county. The present site was purchased by Isaac Norris and William Trent from William Penn, Jr., in 1704, and was originally known as Norriton plantation. When Montgomery county was created in 1784 the Pennsylvania legislature instructed that its courthouse be erected in Norriton township along the Schuylkill, and the community which grew around the courthouse was named Norristown and incorporated in 1812. The river and then a canal encouraged its growth, and in 1834 it obtained a railroad connection with Philadelphia. The city rises on gradual slopes northward from the river, with factories on the river shore giving way to increasingly better residential districts as the ground rises. Manufactures include metal and fibre products, machinery, drugs and tires. For comparative population figures *see* table in PENNSYLVANIA, *Population.* (R. F. WE.)

NORRKÖPING, a major port and industrial town of Sweden in the *län* (county) of Östergötland, stands on the Motala river 3½ mi. above its outflow into the Baltic trough through an inlet known as Bråviken, 113 mi. S.W. of Stockholm. Pop. (1965) 102,043. In the neighbourhood are some remarkable *hällristningar* (rock carvings) of the Late Bronze Age. The town was founded about 1350 and received its charter in 1384. Frequent fires (notably in 1719 when the Russians burned the town during the Northern War) have caused rebuilding on modern lines. The more important buildings include St. Olai church (1767; restored 1949); the town hall (1910); Hedvig's church (1673); two medieval churches, at Östra Eneby and Tingstad (with unique mural paintings); Holmen tower (1751); the grammar school (1862) and technical school (1959); and the museum and art gallery (1946). Louis de Geer (1587–1652), a Dutchman, is credited as being the first to introduce industry successfully there. The basis for development was the falls in the river, which afford motive power for the textile industry (which dominated Norrköping from the 1660s to the 1950s) and for factories producing food products, paper, lithography, radio and television sets, farm equipment, rubber and chemicals. The completion in 1961 of the fairway, the Lind canal, permits the harbour, now one of the most important in Sweden, to take vessels up to 30 ft. draft. Norrköping is a focus for both rail and road transport between Stockholm and the south and west of Sweden; there is an airport at Kungsängen on the eastern outskirts. (AR. J.; K. V. S.; B. H. HE.)

NORSE MYTHOLOGY: *see* GERMANIC MYTHOLOGY AND HEROIC LEGENDS.

NORTE DE SANTANDER, a department of the republic of Colombia, located in the eastern Cordillera adjacent to Venezuela. It was created in 1910 from the provinces of Cúcuta, Ocaña and Pamplona, which formed the northern part of the department of Santander. Area 8,037 sq.mi.; pop. (1964) 534,486. The eastern Cordillera bifurcates in Norte de Santander, one arm continuing northward as the Sierra de Ocaña and Sierra de Motilones while the other bends eastward to form the Venezuelan Andes. The largest rivers in the department drain into Lake Maracaibo. The Catatumbo region, near the Venezuela border, is an important oil-producing area. Agricultural products are grown largely for local use. In the cooler uplands wheat, potatoes, barley, maize and

horse beans are the principal crops. Coffee and sugar cane are grown on the middle slopes and lower valleys, as in the vicinity of the capital city of Cúcuta, pop. (1961 est.) 142,230. (Js. J. P.)

NORTH, BARONS. The English title of Lord North of Kirtling was created in 1554 for EDWARD NORTH (*c.* 1496–1564), a successful lawyer, clerk of the parliament (1531–40) and chancellor of the court of augmentations (1544–48). He was succeeded by his eldest son ROGER (1531–1600), 2nd baron, a courtier and soldier who married the daughter of Lord Chancellor Rich. Edward's second son was Sir Thomas North (*q.v.*), the translator of Plutarch. The 2nd baron's grandson DUDLEY (1582–1666), 3rd baron, son of Sir John North and of Dorothy, daughter and heiress of Dr. Valentine Dale, was educated at Cambridge and in 1600 married Frances, daughter of Sir John Brocket of Brocket hall, Hertfordshire. He was a prominent figure at the court of King James I and was a close friend of Prince Henry. In 1606 he discovered the springs of Tunbridge Wells, which cured North himself of a complaint and quickly became famous. He supported and subscribed to the expedition to Guiana made by his brother Roger North (*c.* 1585–*c.* 1652) in 1619, and when Roger departed without leave Dudley was imprisoned for two days in the Fleet prison. In 1626 he attached himself to the party of Lord Saye and Sele who was in sympathy with the aims of the house of commons, but when the Civil War broke out North took no part in it. In 1645 he was placed on the admiralty commission and acted as lord lieutenant for Cambridgeshire. He died at Kirtling on Jan. 16, 1666.

His elder son DUDLEY (*c.* 1602–1677), 4th baron, increased the family fortune by marrying Anne, the daughter of Sir Charles Montagu, brother of the 1st earl of Manchester. He was an accomplished and studious man. His numerous children included Francis (1704–1790), who became lord chancellor as Lord Guilford; Sir Dudley North (*q.v.*; 1641–1691), the economist; John (1645–1683), who became master of Trinity college, Cambridge, and professor of Greek in the university; and Roger North (1653–1734), the lawyer and historian. The eldest son CHARLES (1635–1691), 5th baron, was created Lord Grey of Rolleston (1673) during his father's life. Charles's son WILLIAM, 6th baron, died without issue in 1734, and the barony passed to a cousin FRANCIS NORTH, 3rd Baron Guilford and afterward 1st earl of Guilford (*see* GUILFORD, BARONS AND EARLS OF).

His son FREDERICK (1732–1792), 2nd earl of Guilford, is historically famous as Lord North, prime minister from 1770 to 1782 (*see* NORTH, FREDERICK NORTH, Lord). Frederick's son GEORGE AUGUSTUS (1757–1802), 3rd earl, left no male issue and the barony of North fell into abeyance till 1841 when it vested in one of his daughters SUSAN (1797–1884), wife of John Sidney Doyle, who took the name of North. Her son WILLIAM (1836–1932) succeeded as 11th baron, the title now being separate from that of Guilford. His great-grandson JOHN DUDLEY (1917–1941), 13th baron, succeeded to the title in 1938 but the title again fell into abeyance when he was killed on active service in 1941.

NORTH, SIR DUDLEY (1641–1691), English merchant, civil servant and economist, was born in Westminster on May 16, 1641, 4th son of Dudley, 4th Lord North (*see* NORTH, BARONS). He entered the Levant trade at an early age and spent many years residing in Smyrna and Constantinople and traveling, finally returning to England, a wealthy man, in 1680. He then served under Charles II as one of the sheriffs of the City of London and received a knighthood; under James II he was appointed a commissioner of customs; a confirmed Tory, he retired from public affairs shortly after the revolution of 1688. He died on Dec. 31, 1691.

His fame rests on the contribution to political economy made in his *Discourses Upon Trade: Principally Directed to the Case of the Interest, Coynage, Clipping, Increase of Money*, published anonymously in 1691 or possibly 1692. This work attracted little attention until rediscovered and reprinted in 1822, after James Mill had hailed the importance of Sir Dudley's ideas as summarized in the biography by his brother, Roger North, published in 1744. Research suggests that the preface of the *Discourses* and perhaps some concluding paragraphs advocating freedom of trade and enterprise were contributed by Roger.

The *Discourses*, though brief and aphoristic, are probably the most thoroughgoing statement of free-trade theory made in the 17th century. Though the older view is taken of trade as the exchange of superfluities, it is insisted "that the whole world as to trade, is but as one nation or people, and therein nations are as persons." Sumptuary laws and legal restrictions on interest rates are denounced as harmful and ineffective. Subsequent monetary doctrines are anticipated in the insistence that the supply of money can be left to free market forces "without any aid of politicians." The *Discourses* conclude: "It is peace, industry, and freedom that brings trade and wealth, and nothing else."

See J. R. McCulloch (ed.), ***Early English Tracts on Commerce*** (1856; reprinted 1954); W. Letwin, "The Authorship of Sir Dudley North's *Discourses on Trade*," *Economica*, vol. xviii, no. 69 (Feb. 1951). (T. W. H.)

NORTH, FREDERICK NORTH, LORD, afterward 2ND EARL OF GUILFORD (1732–1792), prime minister of Great Britain during the American Revolutionary War, for the conduct of which he was widely attacked. He was born in London on April 13, 1732, and was educated at Eton and Trinity college, Oxford. Elected member of parliament for Banbury at the age of 22, he represented the town (of which his father was high steward) for nearly 40 years. The duke of Newcastle made him a lord of the treasury in 1759 and he held this office under Lord Bute and George Grenville until 1765. On the fall of Lord Rockingham's first ministry in 1766 he was sworn a member of the privy council and made paymaster general by the duke of Grafton. On the death of Charles Townshend in Sept. 1767 he became chancellor of the exchequer.

North succeeded Grafton as prime minister in Feb. 1770 and continued in office for 12 of the most eventful years in English history (*see* ENGLISH HISTORY). George III had at last clinched the defeat of the Newcastle-Rockingham connection and found in North a congenial chief minister. The path of the minister in parliament was a hard one; he was popular and an able debater but at times he had to defend measures which he had not designed and of which he had not approved, and this too in the house of commons in which the oratorical ability of Edmund Burke and Charles James Fox was ranged against him. During peacetime North's financial administration was sound but he lacked the initiative to introduce radical fiscal reforms. The most important events of his ministry were those concerned with the American Revolution (*q.v.*). He cannot be accused of causing it, but one of the first acts of his ministry was the retention of the tea duty, and it responded to the Boston Tea Party with the Coercive acts of 1774. Underestimating the colonists' powers of resistance, he attempted to combine severity and conciliation. He faced war halfheartedly and was easily depressed by reverses; after 1777 it was only the king's repeated entreaties not to abandon his sovereign to the mercy of the Rockingham Whigs that induced him to defend a war which at times he felt to be both hopeless and impolitic. In March 1782 he insisted on resigning, after the news of Lord Cornwallis' surrender at Yorktown made defeat in the house of commons imminent. He had been rewarded for his assistance to the king by honours for himself and sinecures for his relatives, but in April 1783 North formed a famous coalition, much to George III's disgust, with Fox and became secretary of state with him under the nominal premiership of the duke of Portland. The coalition went out of office on Fox's India bill in Dec. 1783. For about three years North continued to act with Fox in opposition, but failing eyesight then caused his retirement from politics. He succeeded to the earldom of Guilford on his father's death in 1790 and died in London on Aug. 5, 1792.

See Sir Lewis Namier and J. Brooke, ***History of Parliament: the House of Commons, 1754–1790***, vol. iii (1964). (I. R. C.)

NORTH, SIR THOMAS (1535–1603?), English translator whose version of Plutarch's *Lives* was the source for many of Shakespeare's plays, was born in London on May 28, 1535. Possibly a student at Peterhouse, Cambridge, he was entered at Lincoln's Inn, London, in 1557, where he joined a group of young lawyers interested in translating. In 1574 North accompanied his brother Roger, 2nd Baron North, on an embassage to France. Thomas North had an extensive military career: he fought twice

in Ireland as captain (1582 and 1596–97), served in the Low Countries (1585–87?) and trained militia against the threatened invasion of England in 1588. He was knighted about 1596–97. He was justice of the peace for Cambridge in 1592 and 1597, and pensioned by the queen in 1601. He died in 1603 or soon afterward.

In 1557 North translated (from the French) Antonio de Guevara's *Libro del emperador Marco Aurelio con reloj de principes* under the title *Diall of Princes* (K. N. Colvile, ed., 1919). Guevara's elaborate prose influenced many early English translators, but North did not originate the mannered style which culminated in Lyly's *Euphues.* His translation (from the Italian) of oriental beast fables, *The Moral Philosophie of Doni* (1570; J. Jacobs, ed., 1888), was rapid and colloquial narrative. Plutarch's *Lives of Noble Grecians and Romans,* translated in 1579 from the French of Jacques Amyot, has been described as "after Malory's *Morte D'Arthur* and the *Book of Common Prayer* the earliest great masterpiece of English prose" (F. O. Matthiessen, *Translation: an Elizabethan Art,* Harvard University Press, Cambridge, 1931). There is an edition by C. F. T. Brooke, 5 vol. (1929–30). Shakespeare actually paid North the compliment of putting his prose directly into blank verse. (H. H. Ds.)

NORTH, THE, as a section of the United States, has always had rather indefinite boundaries, and its boundaries have varied from one period to another. In colonial times a distinction was sometimes drawn between the northern and southern mainland settlements of British America, with the Potomac river as the dividing line. Thus, in *The Administration of the Colonies* (1764), Thomas Pownall, who had become royal governor of Massachusetts in 1757, referred to the "Northern British Colonies" as distinct from the "Carolinas and other southern Colonies." More commonly, however, a threefold division was made: New England, the middle colonies and the south.

After the American Revolution the same kind of sectional classification was continued and, with the growth of the nation, was expanded. The pioneer American geographer Jedidiah Morse, in *The American Geography* (1789), wrote of "the *Northern,* or more properly *Eastern, Middle,* and *Southern* States." Later, as population spread beyond the Allegheny mountains, Morse and other geographers added the West as a separate section. In retrospect, the historian Frederick Jackson Turner (in *The United States, 1830–1850: the Nation and Its Sections,* 1935) defined and described a total of six sections as existing in the 1830s and 1840s. These sections consisted of (1) New England, (2) the middle Atlantic states, (3) the south Atlantic states, (4) the south central states, (5) the north central states and (6) Texas and the far west.

As early as 1796, in his farewell address, George Washington used the expressions "the North" and "the South" (as well as "the East" and "the West"). He warned that the federal union would be in danger if a time ever came when political differences were based upon geographical lines. By 1860 that time was at hand. Americans then commonly talked as if there were but two sections, the North and the South, and as if there were a fundamental conflict of interests between them.

The North, as it developed during the period between the Revolution and the Civil War, consisted of the free states. At the time of the Revolution, or soon afterward, 7 of the original 13 states abolished slavery. By the Northwest ordinance of 1787 slavery was prohibited in the Northwest Territory, and as new states were formed from that territory they made slavery illegal within their boundaries. By the Missouri Compromise of 1820 slavery was banned in the Louisiana Purchase north of latitude 36° 30′ except for Missouri, which was admitted to the Union as a slave state. California became a free state by its own choice and in accordance with the Compromise of 1850. By the Kansas-Nebraska act of 1854 the slavery prohibition of the Missouri Compromise was repealed; slavery was to be permitted in Kansas and Nebraska if the settlers in those territories desired it, but in 1861 Kansas was admitted with a constitution forbidding slavery. As of 1861 there were 19 free and 15 slave states, and the boundary between them followed the Mason and Dixon line (which separated Pennsylvania and Maryland), the Ohio river, and (except for Missouri) the latitude 36° 30′.

The question of slavery in the territories was the most prominent of the political issues that tended to unite the North and bring it into conflict with the South during the 1850s. Outright abolition was not a serious issue. Though a majority of northerners had come to feel that slavery was in some degree morally wrong, comparatively few of them joined or supported antislavery societies and still fewer believed that the federal government possessed the constitutional power to abolish slavery in the states where it was already established. In addition to the territorial question, however, there were matters of economic policy on which the North and the South differed. Generally the North favoured and the South opposed federal aid to industry and transportation through such measures as protective tariffs and direct expenditures for roads and canals.

The political differences between the North and the South reflected the differential economic and social development of the two parts of the country. In the North of the 1850s industrialization and urbanization had proceeded and were proceeding much further and faster than in the South. The ethnic composition of the people was more varied, with a considerably larger number of German, Irish and other immigrants settling in the North (though the proportion of Negroes remained smaller than in the South). The northern population was growing faster, the free states gaining by 41% and the slave states by only 27% between 1850 and 1860. There was more social and intellectual ferment in the "Yankee world," with its numerous and productive authors and its reform movements of all kinds. There was also a higher rate of both school attendance and literacy.

By the 1850s distinctions between the East and the West were obscured by those between the North and the South. At one time the West—both northwest and southwest—had formed something of an economic unit, with ties of trade that followed the Ohio-Mississippi river route. Then these ties were weakened and largely replaced by new ones joining the northwest with the northeast rather than the southwest. Among the new ties were the commerce of the Great Lakes and the Erie canal (opened in 1825) and the traffic of the railroads connecting the northwest with northeastern seaports. Chicago, for example, had a rail connection with New York by 1852.

The North attained its highest self-consciousness as a section during the Civil War. At that time "the North" was synonymous with "the Union." It included not only the free states but also the border slave states of Delaware, Maryland, Kentucky and Missouri (though there was considerable pro-southern sentiment in the border area, and Kentucky and Missouri were represented in the congress of the Confederate States as well as that of the United States). The North gained two states with the admission of West Virginia in 1863 and Nevada in 1864. Except for a brief period at the beginning of the war, the North maintained control of all the western territories except the Indian Territory (Oklahoma).

The 23 states of the Union (not counting West Virginia or Nevada) had a population of approximately 22,000,000, as compared with approximately 9,000,000 (including more than 3,500,000 slaves) for the 11 states of the Confederacy. The 23 states contained a disproportionate share of the economic resources of the entire country. The North possessed, for example, 81% of the factories and produced 75% of the nation's wealth.

But regional differences within the North reappeared even during the Civil War, when sectional unity was at its greatest. These wartime differences could be seen in such political controversies as that between Illinoisans demanding internal improvements (roads and canals) at federal expense and Pennsylvanians opposing them. The differences could be seen also in the agitation of the midwestern Peace Democrats, the so-called "Copperheads," who were motivated more by antagonism to the northeast and especially to New England than by attraction to the South.

During the postwar reconstruction (1865–77) sectional self-consciousness persisted in the North, and even after that time it was kept alive by Republican politicians who resorted to "waving the bloody shirt" (*i.e.*, recalling wartime hatreds) for electioneering purposes. But in the last two decades of the 19th century

East-West division in national politics often predominated over the North-South division. In the reform movements culminating in the Populist revolt, western and southern farmers aligned themselves against the "interests" of the East. Thus "the North" lost some of its validity as a sectional concept.

Meanwhile, in the later as in the earlier 19th century, geographers recognized no single North but divided the northern part of the United States into several regions. Thus William Swinton, in his *Elementary Course in Geography* (1875), listed New England, the middle states, the western or central states and the Rocky Mountain or Pacific states, in addition to the southern states. The federal census, in 1910 and after, included the northern states in the following classifications: New England, middle Atlantic, east north central, west north central, mountain and Pacific. The remaining census classifications (south Atlantic, east south central, west south central) included certain states that were at least partly northern in background and spirit—such as Delaware, Maryland, West Virginia, Kentucky, Oklahoma and Texas, not to mention the District of Columbia.

In the 20th century, geographers, sociologists, historians, business organizations and governmental agencies adopted various regional concepts to suit their own special purposes. It became less feasible than ever to treat the North as a single, clear-cut entity. Yet "the North" continued to be mentioned frequently in ordinary discourse. The term was used chiefly to indicate what was opposite from the South. Sectional self-consciousness both in the North and South increased with the rise of civil rights for Negroes as a major issue of national politics, especially after the supreme court's decision against school segregation in 1954. While, with respect to formal equality for Negroes, northern folkways were being resisted in the South, the northern pattern of life in many other respects was being readily accepted. Industrialization and urbanization, now proceeding even more rapidly in the South than in the North, tended to make the former more and more like the latter.

(R. N. Ct.)

NORTH ADAMS, a city of Berkshire county in northwestern Massachusetts, U.S., on the Hoosic river, is located in the northern Berkshires, 4 mi. S. of the Vermont border and 19 mi. N.E. of Pittsfield.

Within the city limits is a natural bridge 50 to 60 ft. high across Hudson brook. Among the city's educational facilities is State College at North Adams (1897). Manufactures include boots and shoes, machinery, electronic components, wire, paper, textiles and chemicals. Limestone is also quarried in the vicinity. In the western part of the city are the ruins of Ft. Massachusetts, built in 1745 by the Massachusetts Bay colony as a frontier defense and burned in 1746 by the French and Indians. Initially settled about 1737, North Adams had several false starts before being permanently settled in the 1770s by Quakers from Rhode Island. Incorporated as Adams in 1778, North Adams was set off and incorporated as a separate town in 1878; it was chartered as a city in 1895. For comparative population figures *see* table in MASSACHUSETTS: *Population.*

(R. C. L. S.)

NORTH AFRICA is that part of the African continent between the Mediterranean coast and the Sahara desert. The area in which the vast majority of its 50,000,000 inhabitants live is restricted to a fairly narrow coastal belt and to the lower Nile valley. Geologically, climatically and historically it belongs to the Mediterranean and to "White Africa," in contradistinction to "Black" or Negro Africa, the subcontinent lying south of the Sahara. The peoples of north Africa are relatively advanced and usually Muslim in religion. At various times they have been subject to European political control, and the economic links and cultural influences across the Mediterranean from southern Europe have usually been strong.

Most of north Africa has a marked dry season with low rainfall, and cultivation depends frequently upon irrigation. Egypt is an outstanding example of a country that can support more than 25,000,000 people, admittedly at a low standard of living, through intensive production based on the skilful application of irrigation. Elsewhere European settlers have been established, notably in Morocco, Algeria, Tunisia and in parts of Libya, and were formerly responsible for much agricultural production. Mineral deposits include iron ore, phosphates and petroleum, and manufacturing industries are well developed in many of the rapidly expanding towns.

There have been important political changes throughout north Africa since World War II. Reference should be made to the separate articles on the countries making up the region: ALGERIA; EGYPT; LIBYA; MOROCCO; TUNISIA; all these are independent sovereign states. *See* also AFRICA; ARAB; ATLAS MOUNTAINS; BARBARY; BERBER; LIBYAN DESERT; MOORS; NILE; SAHARA.

(R. W. SL.)

NORTHALLERTON, an urban district, market town and the administrative capital of the North Riding of Yorkshire, Eng., in the Richmond parliamentary division, 32 mi. N.W. of York by road. Area, 5.7 sq.mi. Pop. (1961) 6,726. It is on a slight eminence at the foot of the Cleveland and Hambleton hills, 3 mi. from the bank of the river Swale, where the western scarp of the Wolds causes the Vale of York to narrow to a width of 10 mi. forming the Northallerton Gate. Thus situated, midway between the coast and the manufacturing areas in the west of the county, it forms the gateway to the dales. The Romans are thought to have had a signal station there, on the terraced mounds of Castle hills, and the Conqueror chose it as a camping place for his army in 1068. According to the Domesday survey the Normans ravaged the area to such an extent that it was still waste in 1086. Northallerton suffered much from warfare with the Scots. In 1138 they were defeated by the English in the battle of the Standard, and their bodies were thrown into pits at a site still known as Scots Pits lane. In 1174 the castle was destroyed and in 1317 the town was burned by the Scots under Robert Bruce. Northallerton had been given by William Rufus to the bishop of Durham, whose successors continued to hold it until it was taken over by the ecclesiastical commissioners in 1865. According to an inquisition taken in 1333, the town, markets and fairs were held by the burgesses governed by two reeves and the bishop's bailiff. This form of government continued until 1851, when a local board was formed, and this was superseded by an urban district council in 1894. As a borough by prescription, Northallerton returned two members to the parliament of 1298, but was not represented again until 1640 when its earlier privileges were restored. From 1832 to 1885 it returned one member.

The church of All Saints, a cruciform building dating from 1120, is mainly Early English with a Perpendicular tower. Near it is the ancient Porch house, where Charles I was imprisoned, and the site of the Carmelite friary founded in 1356 by Edward III. Mount Grace priory, founded in 1397, was destroyed at the dissolution of the monasteries. Its ruins, 5½ mi. N.E. of the town, display one of the most complete ground plans in England of a pre-Reformation Carthusian monastery. The North Riding county library building was opened in 1938 in Northallerton. The town hall was built in 1874 with a market hall on the ground floor. The county hall was opened in 1906 and the county courthouse in 1936. The town has a considerable trade in dairy farming and has held a weekly fair since 1205. There are flour mills, metalworks, tanning and leather finishing, spring manufacturing, agricultural engineering, dried milk making, timberyards and laundering.

NORTH AMERICA, the northern part of the land mass comprising the Americas of the western hemisphere, which includes continental United States and Canada (sometimes referred to as Anglo-America), and Mexico and the countries and islands of the Caribbean area (generally called Middle America; *q.v.*). As thus defined, it is the third largest continent, occupying more than 9,000,000 sq.mi., slightly above 16% of the earth's land area, with a population of about 266,000,000.

North America is bounded on the north by the Arctic ocean, on the west by the North Pacific ocean and the Bering sea, on the east by the North Atlantic, with the Gulf of Mexico and the Caribbean sea to the southeast. It is separated in the northeast from Greenland (which is situated on the North American continental shelf and is sometimes considered part of North America) by Baffin bay. To the south, it is connected with South America by the Isthmus of Panama at lat. 7°–9° N., and extends for more than 5,000 mi. to 83° 7′ N. on the north coast of Ellesmere Island. Its

greatest width is about 4,000 mi., roughly bisected by the meridian of 100° W.

Tremendous cultural differences exist between the two major components of the continent. Canada and the United States have both experienced the colonizing effects of Great Britain, and many evidences of their common British heritage are evident, including a common language, common political and legal institutions, and many everyday customs. Middle America, on the other hand, received its cultural imprint more from Spain and Portugal, and like the countries of South America is primarily Latin in its culture.

Economic differences are as marked as social and political contrasts. Canada and the United States are outstandingly rich in natural resources and possess highly industrialized economies. In Middle America, farming, often at a subsistence level, is still the dominant activity; industrial production is very small when compared with that of the two large nations to the north, and the level of prosperity is decidedly lower.

This article is divided into the following sections and subsections:

It is not intended to present here the story of nations or of tribal peoples, but to summarize the continent's main natural, economic, anthropologic, historic and demographic aspects. These features receive further treatment in separate articles on the individual countries and regions, the major natural features, tribes and other specific subjects discussed. (C. F. Ko.)

I. PHYSICAL GEOGRAPHY

1. Geological History and Physiography.—North America may be divided into five areas which are roughly homogeneous with respect to the types of rock present and their structural relationships, the geologic history of the region and its present appearance.

Canadian Shield.—The Canadian shield includes some of the oldest rocks on the face of the earth. The region, as a whole, is composed of ancient crystalline rocks whose complex structure attests to a long history of uplift and depression, mountain building and erosion. Some of the ancient mountain ranges may still be recognized as a ridge or belt of hills, but the present appearance of the physical landscape of the Canadian shield is not so much a result of the folding and faulting and compression of the rocks millions of years ago as it is the work of ice in relatively recent geologic time. During the Pleistocene, the vast continental glaciers which covered northern North America had this region as a centre. The ice, in moving to the south, scraped the land bare of its over-

FIG. 1—PHYSIOGRAPHIC REGIONS OF NORTH AMERICA

lying mantle of weathered rock. Some of this material was deposited on the shield when the ice melted, but the bulk of it was carried south to be deposited in the Central lowland.

The resulting surface consists of rocky, ice-smoothed hills with an average relief of 100 ft., and irregular basins, which are mostly filled by lakes or swamps. In places, the old mountain ranges may be recognized by hills several hundreds of feet in height.

Central Lowland.—South and west of the Canadian shield the ancient basement of crystalline rocks was covered by sediments derived from mountains to the west and east, and from the shield itself. This broad region was little affected by the forces that warped the earth's crust. Domes and arches, basins and troughs can be detected in the structure of the old Paleozoic sediments of the central lowland, but within any local scene the rocks appear to be almost flat lying. The western portion of the lowland was veneered by more recent Mesozoic and Tertiary sediments derived from the Rocky mountains. These were eroded by the relatively few streams of the dry Great Plains into steep-sided river valleys and canyons separated by broad flat uplands.

The debris carried by the glaciers of the Pleistocene was dumped east of the Missouri river and north of the Ohio river. The tongue-like glacial lobes formed ridges and rows of hills 100 to 200 ft. high about their margins (end moraines) although most of the area within the lobes has a more even surface with hills ranging from 20 to 100 ft. in height. The disorder with which the drift was deposited resulted in many undrained pockets or depressions which filled with water to form lakes or swamps. South of the glacial border the old sediments form a hilly transition to the Appalachian highlands and their western extension—the Ozark-Ouachita upland. In this zone, the relief ranges up to several hundred feet, and is usually roughest along the many stream valleys which drain the area.

Appalachian Highlands.—Paleozoic sediments deposited at roughly the same geologic time as those of the central lowland were subjected to considerably greater uplift and folding and faulting in the area to the east. The area of most intensive mountain building is represented by the crystallized sediments of the Piedmont and the Blue Ridge mountains in the southern portion of the highlands and by the mountains of New England and eastern Canada to the north.

Directly to the west of the crystallized zone are ridges and valleys, their northeast-southwest lineament attesting to the compression from the east. Successive periods of uplift and erosion, accompanied by folding and faulting, created the complex structures that permitted the present topography to develop on the alternating hard and soft rocks of the area. The compressional forces died out to the west, and the land, although uplifted further and hence with greater relief, has much the same structural characteristics of the eastern portion of the central lowland. Throughout this hill region and the ridge and valley area, the relief ranges from 300 to 1,500 ft., with the steepest slopes and highest hills to be found along the valleys of the many streams which carve the area. (*See* APPALACHIAN MOUNTAINS.)

Coastal Plain.—The simplest structure of North America is to be found in the coastal plain. This is an area of relatively soft, young (Mesozoic and Tertiary) sediments overlapping the crystalline rock of the Piedmont in the east, the central lowland in the west, and extending as far south as the Yucatan peninsula. The rocks dip uniformly toward the sea, and the margin of the plain gives evidence of its youth in its extensive marshes and swamps, any of which could be converted to ocean floor by a rise in sea level of only a dozen feet.

The dip of the plain toward the sea has exposed successive bands of rock of varying resistance to erosion, creating belts of hills 100 to 200 ft. high alternating with flattish vales of very low relief.

Western Cordillera.—Somewhat younger than the ancient mountains of the Canadian shield and those of the Appalachian area, the high rugged mountains of the western Cordillera exhibit the greatest relief of the continent. The structural picture is so diverse as to include almost every conceivable type. The general north-south lineament of the ridges of varying rock type defines also the direction of the valleys and structural depressions which are filled with debris eroded from the mountain slopes. In the north and on the highest peaks in the south, glaciation has sharpened the ridge crests and provided still more debris with which to choke the valleys. Volcanoes, both active and dead, form some of the highest peaks and are often even the more impressive because of their relative isolation from other high mountains. Extensive outpourings of lava and the exclusion of some areas from intensive folding and faulting while they were being uplifted thousands of feet produced vast tablelands and plateaus. The rocks in this region range from the youngest sediments to the oldest crystallines, depending on the geologic history of the particular local unit.

Drainage.—The successive crustal movements by which North America was developed have determined the growth of several great river systems. The broad upheavals which developed the medial plains had the effect of engrafting many rivers from the eastern and western highlands upon trunks of unusual dimensions. Thus the Mississippi system, some of whose eastern tributaries probably date from early Mesozoic times, received great reinforcement by the addition of many long western branches in late Tertiary time, roughly contemporaneous with the uplift of the southern coastal plain, by which the lower trunk of the river was extended from its mid-length into the gulf. The present headwaters of that river trunk to which the name Mississippi has been rather arbitrarily applied are of very modern date, as they are consequent upon the abundant glacial deposits of northern Minnesota; and relatively modern courses appear to have been taken by the earlier-born Ohio and Missouri rivers around the margin of invading Canadian ice sheets, which displaced them from earlier courses.

The evolution of the Mackenzie resembles that of the Mississippi in a general way, but it presumably was much affected by glacial erosion and deposition, in consequence of which it, like the St. Lawrence, has many large lakes in its course. The regime of this great north-flowing river is strikingly unlike that of its south-flowing analogue on account of its course being from a warmer to a colder climate; hence while Mississippi floods have a free southward discharge, the floods of the Mackenzie have an obstructed northward discharge due to ice dams. Indeed, but for the complications that appear to be related to the outspread of Laurentian ice sheets, the areas drained by the Nelson and the St. Lawrence, now flowing to Hudson bay and St. Lawrence gulf, would be discharged by the Mackenzie and Mississippi. For a time, during the presence of the ice sheets, that simpler system was realized for the Mississippi, when it carried to the Gulf of Mexico much drainage now received by the St. Lawrence and Nelson; the flood plain of its lower trunk was probably given its wide breadth at that time.

Lake Superior is peculiar in apparently attributing its great depth to a somewhat pronounced displacement of its basin floor, in addition to whatever deepening it gained by glacial erosion.

The chief rivers that discharge to the Pacific rank below those that discharge to the Atlantic; but the Yukon, flowing from farther Canada and inner Alaska, is one of the great rivers of the world. The Columbia, of hardly inferior rank, drains a large area of the Cordilleran system in Canada and the United States; it is peculiar in having one of its head branches rise at the eastern base of the Rocky mountains in Montana, so that its waters flow westward through all the Cordilleran ranges of its latitude. The Colorado discharges a muddy current into the Gulf of California. (*See* also separate articles on the rivers.)

2. Climate.—The climatic character of an area derives from the operation of weather mechanisms over a long period of time. The weather of North America is of two main types: mid-latitude, the result of conflict between polar and tropical air; and tropical, in which cold polar air plays no part, and hence, in which frost is uncommon or nonexistent.

Mid-latitude Weather and Climate.—The vagaries of the weather of most of the United States and Canada are because of the location of the North American land mass in a zone of interaction between polar and tropical air masses. Air generally assumes the character of the surface over which it lies for periods of several days or weeks. As a result of the general circulation of the atmosphere, air masses are drawn together over North America from such unlike source areas as the Canadian arctic and the expanses of the Atlantic ocean in the tropics. The differences in the heat and moisture characteristics of these air masses result in the development of storms, known as cyclones. The zones of conflict between unlike air masses are known as storm tracks, the cyclones moving generally from west to east. As the northern hemisphere warms with the increasingly vertical attitude of the sun's rays in summer, the storm tracks shift northward. These shifts in the position of the storm tracks largely determine the nature of the climate of various portions of North America.

The Canadian arctic lies generally to the north of these storms, and is characterized by cold winters and cool summers with little precipitation in either season.

Winter is the time of greatest storminess. Many cyclones enter the continent from the North Pacific ocean, having originated over eastern Asia or the waters immediately off the Asiatic coast. These cyclones deliver little moisture in the lowlands, but the mountains of the western Cordillera cause lifting and chilling of the air, thus ensuring heavy rain and snowfall on the western slopes. Most of the storms enter the continent north of San Francisco bay, but an occasional storm delivers heavy rain to southern California.

As the cyclones from the North Pacific ocean move over the western Cordillera, they lose most of their moisture. Often these cyclones are rejuvenated as they descend the leeward slopes of the mountains into the central lowland. The more northerly of these are centred on the Alberta storm track, delivering small quantities of snow, but with a high frequency of occurrence, to the northern

central lowland and the Canadian shield, especially in the vicinity of the Great Lakes and the St. Lawrence valley. The more southerly storm tracks, called the Colorado and Texas cyclones, are able to draw in air from the Gulf of Mexico. This warm, moist tropical air enables much heavier snowfall to be delivered to the central lowland and the St. Lawrence valley, but with less frequency than is the case with the Alberta-type storm. This air, in crossing the southeastern United States, usually delivers heavy rain showers as well, so much so that some portions of the lower Mississippi valley actually receive more moisture under these conditions than in the summer season.

During the summer half year, the cyclone belts shift northward. The northwest Pacific coast receives storms from the Asiatic source area, but they are somewhat less frequent during this season and result in less rainfall than in winter. The shift of the storm tracks away from the southwestern United States creates desert conditions in the lowlands. The highlands receive thunderstorm rainfall from an occasional errant air mass of Atlantic ocean origin.

East of the Rockies a somewhat different picture prevails. The northward shift of the cyclone belts results in a lowered frequency of rainfall in much of the area, but this is more than offset by the torrential nature of the rainstorms that do occur. This is due to the tropical characteristics of the air which is drawn into the North American land mass from the Gulf of Mexico and the tropical areas of the Atlantic ocean. Most of the eastern United States and Canada receive the bulk of their moisture from summer thunderstorms and the cyclones which draw the tropical air northward.

Tropical Weather and Climate.—Tropical North America (Central America and the islands of the Caribbean and the Gulf of Mexico) is little affected by the mid-latitude cyclones. Instead, the weather and hence the climate of these areas is characterized by relatively monotonous heat, unaffected by frost except in the high mountains. The seasons are recognized by their wetness or dryness, rather than by cold or warmth.

Just as the bulk of mid-latitude North America receives most of its moisture during the northern hemisphere summer, so does this tropical regime. The mechanisms causing moisture to fall are more complex in the tropics, but seem also to be associated with the vertical attitude of the sun's rays. The same air that delivers moisture to the eastern United States and Canada in the summer drops rain from thunderstorms as it surges through this area. Hurricanes are common in late summer, and are also responsible for heavy precipitation.

The northern hemisphere winter is characterized by less frequent rain showers in this area, and by a predominance of clear, sunny skies.

3. Vegetation and Animal Life.—Patterns of vegetation and animal life generally conform to the broad controls of climate. On a more local scale, topography and soils have altered and modified these broad zones. Man has also made his impress, changing the pattern and character of the flora and fauna with the use of fire, the clearing of forests, plowing of grasslands, and grazing of domesticated animals. Thus the North American landscape of the 20th century shows the influence of all these factors. Temperature and moisture availability differences set the stage for consideration of the major variations in distribution.

Arctic.—The long cold winters and short cool summers of the far north create an environment that is too harsh for tree growth. Mosses in the extensive bogs, and lichens and short herbaceous plants on the better-drained uplands compose the bulk of the tundra vegetation. Relatively few animal species can exist there. Caribou, musk ox, polar bear and arctic fox are the larger varieties. Lemmings and the arctic hare are characteristic. Hordes of mosquitoes plague summer visitors. Few birds stay the winter, although many species migrate to nest there in the summer.

Subarctic.—Longer and milder summers to the south enable the forest to appear in the form of dwarf birches, willows, alders and spruce. As temperatures become less severe, the taiga or northern coniferous forest covers the landscape. Relatively pure stands of spruce, fir and several species of pine are intermingled with birch, willow, larch and poplar. There is little undergrowth except near

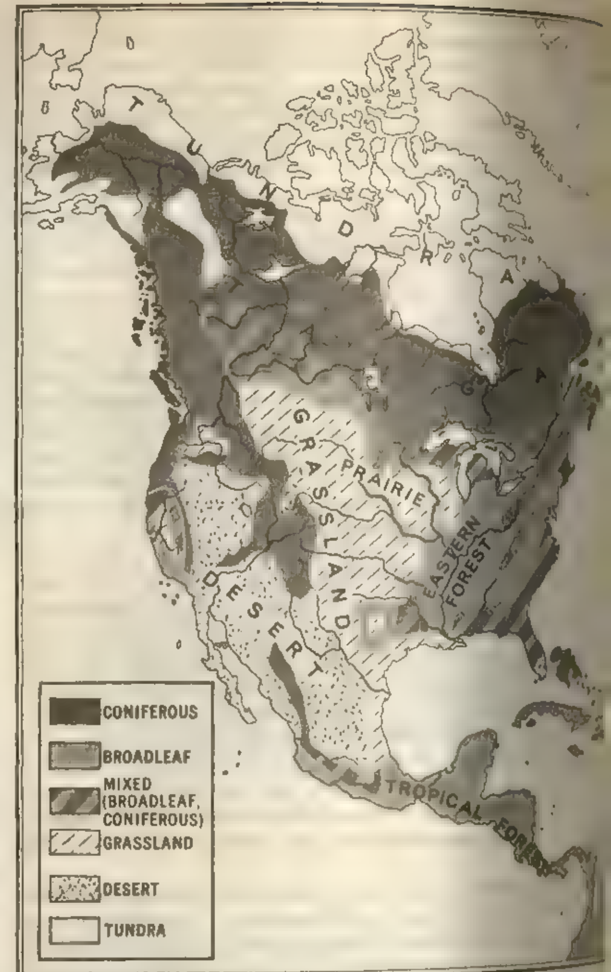

FIG. 2.—VEGETATION SOURCES OF NORTH AMERICA

streams. Carnivores, such as the black bear, lynx, fox an are present, as are deer, moose, elk and caribou. Rodents among them squirrels, porcupines, rabbits and beavers peckers and jays are common birds. Both arctic and sub forms trend far equatorward along the east and west coast where high elevations modify the warmer conditions lower latitudes. The western Cordillera blocks moisture winds and creates rain shadows that set lower timber-line based on aridity. There the conifers give way to desert an land forms.

The windward slopes of the mountains receive heavy pr tion, and near the Pacific ocean dense growth results giant forest trees 200 ft. or more in height. Cold te at high elevations result in an upper timber line vegetation is found above this level, which gradually de one proceeds north until, in central Alaska, trees are fou the valleys.

Eastern Forest and Coastal Plain.—In the central low clones bring warm tropical air as far north as the Gre Deciduous tree forms assume dominance in the landsc natural conditions, and the conifers die out. Birch, bee and oak are predominant in the north, and walnut oak and the tulip tree in the south. Much of the forest ha over, especially on the flatter uplands and in fertile The stream valleys remain wooded and provide shelter smaller mammals and birds that have withstood the pre civilization. Deer and fox may be found where there cover, and skunks, raccoons and muskrats join the squ rabbits as significant forms. Hawks and thrushes are birds. Numerous varieties of insects are present, as are reptiles.

The sandy belts of the coastal plain are generally co

er longleaf pine forests which may be relicts from glacial periods. The stream valleys of the coastal plain are likely to be very poorly drained, with swamp trees such as cypress and gum as dominant forms. The outermost margins of the coastal plain are occupied by marshes in which the characteristic vegetation consists of grass forms.

Grasslands.—Moisture variability from year to year and fire probably combined to slow the extension of forest vegetation into the dry west, after a climatic change had produced desert conditions in the heart of the interior. As a result, the first explorers found a broad belt of grassland between the forested humid east and the deserts of the west. The eastern portion has long been cultivated, but on the drier, western grasses, grazing is still the most significant land use and some semblance of the natural cover remains. The grasslands of the east consist of dense growth of tall varieties, often six feet or more in height. Glades occur in the forests, often on droughty limestone or sand plains.

In the prairie triangle of Illinois and Iowa, or on the margins of the Great Plains in Oklahoma and Texas, the grasses become dominant on the uplands. Only the stream valleys remain in forest or woods, for the break in topography of the belts of bluffs and the dampness of the bottom lands protect the trees from prairie fires and from drought.

The grasses and herbaceous vegetation of the prairies become less dense, and less tall bunch grass forms in the western steppe lands. These in turn form the transition to desert vegetation types in the driest parts of the west. Only along the moist valleys of perennial streams are cottonwoods and other deciduous trees to be found. Shrub forms, such as mesquite, are present in the warmer margins where high evaporation increases dryness, but they did not become dominant until man controlled fire.

Although lack of moisture in summer and occasional blizzards in winter constitute formidable hazards, large numbers of animals are found in the grasslands. Noteworthy were the tremendous herds of bison, which have been practically exterminated. Antelope, coyote, jackrabbits, prairie dogs and ground squirrels are common forms that remain in great numbers. Insects such as grasshoppers and locusts and ants are characteristic. Turtles, lizards and various snakes (some of them poisonous) have adapted to the environment.

Deserts.—In the desert even less moisture is available for plant growth than in the grasslands. The only perennial streams are those which flow from exotic, humid sources. Plants and animals have had to adjust to long periods with little or no moisture. Shrub forms become dominant over grasses; these include sagebrush, greasewood and creosote bush. High evaporation rates and topographic depressions combine to produce high saline concentrations in many of the soils. Thus, salt tolerance is another attribute necessary for plant growth. Around depressions or desert valleys there is often a zonation of plants, with the most salt-tolerant found nearest the centres, and the least on the better-drained uplands. In the driest places numerous forms of cacti are found. Some of these may attain heights of 20 to 30 ft. Much of this landscape is not suited to intensive grazing, and so only in the irrigated valleys was the natural vegetation materially disturbed.

The larger animals have difficulties surviving where water is so scarce. Fox are present and feed on rabbits. Owls, lizards and snakes may be found. But the total numbers and the varieties of wildlife are less than in more well-watered areas.

Tropical Forests.—The dry deserts and grasslands extend well southward into Central America. The better-watered portions of the tropics are covered by a dense growth of broadleaf evergreen trees. Several "stories" of tree and shrub growth are likely, with vines and lianas common. Seasonally well-watered areas are characterized by savanna, a tall grass landscape with scattered trees which are particularly dense near the water courses. Monkeys and squirrels, ants and termites, snakes and a wide variety of colourful birds constitute the animal life. In both vegetation and animal life, the number of species and the density of individuals increase in these frost-free, well-watered climates. *See* also the *Physical Geography* sections of UNITED STATES (OF AMERICA), CANADA, MEXICO, WEST INDIES, CENTRAL AMERICA; and ARCTIC, THE. (N. E. S.)

II. NATURAL RESOURCES

When the pioneers of Anglo-America took possession of the land there was a superabundance of natural resources. Subsequently, wasteful exploitation was not only condoned but frequently encouraged. Vast tracts of virgin timber were destroyed, wild game was killed and soils became eroded. This situation was further aggravated by the severe droughts of the 1930s and the consequent wind erosion in the dust bowl of the high plains. By mid-20th century, the U.S. and Canadian governments, alarmed at the wasteful practices and ignorance, undertook conservation measures and established agencies to study the problem. Genuine attempts are being made to gear the economic system to nature. (*See* WILDLIFE CONSERVATION; NATIONAL PARKS AND NATURE RESERVES; SOIL: *Soil Erosion and Conservation;* NATURAL RESOURCES.)

1. Water Resources.—In North America, as in other parts of the world, water has six major uses: domestic, irrigation, industry, transportation, power and waste disposal. Nearly all of these uses have expanded rapidly, partly because of expanding populations and industries, but also because per capita needs have been increasing rapidly. As a consequence, actual or impending shortages of water have occurred in many parts of the continent, not only in areas of small precipitation but also in many of the more densely populated portions of the humid sections. The availability of water has thus become a major concern for the people of North America.

Man has come to identify three principal sources of water: (1) precipitation, usually as rain or snow; (2) surface supplies, in the rivers, lakes and oceans; and (3) subsurface sources, usually brought to the surface by wells or springs. In North America, few attempts have been made to control precipitation, or to use that source of water directly, but there have been tremendous efforts to conserve waters by constructing reservoirs and other storage facilities in order to provide larger supplies at places not adequately served by lakes, rivers and other natural reservoirs. These reservoirs, both natural and artificial, have become the major source of water for the North American people. Underground supplies, including well water and spring water, were proved adequate only in a few areas with particularly favourable climate and geological conditions.

Water resources must always be viewed in the light of both quantity and quality. In populous industrial areas such as the northeast United States, southeast Canada and the central plateau of Mexico, so much water is utilized for sewage and industrial wastes that adequate domestic supplies are frequently difficult to obtain, in spite of the relatively heavy rainfall and large surface storage facilities of those areas. The natural mineral content of underground waters also varies a great deal, being very high in most areas underlain by limestone rocks and low in areas having acid rocks. In North America nearly all of the plains and plateau areas have limestone rocks and are consequently supplied with hard (mineralized) water from underground sources.

In the arid sections of northern Mexico, the western United States and portions of western Canada, water for irrigation is of prime importance. Giant storage reservoirs are used to hold winter precipitation until the water is needed for summer crops. Many streams in these areas have their sources in high mountains and, since many of the reservoirs are located at relatively high elevations, water power is cheaply and abundantly produced.

The most serious deficiencies of water appear in dry areas that have experienced marked urban development, notably in the Los Angeles (*q.v.*) metropolitan area of southern California where the new demands of a rapidly expanding population have been added to those of irrigation agriculture. An extensive system of aqueducts brings water to the area from the Colorado river; the Feather river project to make available water from the humid northern part of the state was begun in 1960 and a program of securing additional supplies by purification of sea water was projected. Long-distance transportation of water is not confined to

low-rainfall areas, however, since extensive supply systems were constructed to bring water to New York and other urban-industrial centres, usually from highland areas that lie considerable distances inland. In this manner, surpluses of water in many of the less populous areas were created to satisfy needs in metropolitan centres, where local supplies were inadequate.

Water for supplemental irrigation is being used increasingly by farmers in the upper Mississippi valley, where, in summer, short periods of drought may occur. Supplies usually are obtained either from wells or streams, and the severe competition for water prompted several states in that area to enact irrigation laws. Problems of water scarcity have appeared in all parts of the continent where there are considerable numbers of people.

Power, recreation and navigation uses of water differ from the others as they do not materially affect either the quantity or quality of available supplies. Hydroelectric power is most cheaply generated where there is heavy precipitation on high land. The best resources are therefore in the states and provinces that border the north Pacific coast of the United States and Canada, although eastern areas, which have splendid natural storage facilities in the Great Lakes and the lakes of the Canadian shield, also possess important power resources. Water for recreation is available in all sections of the continent, either in natural lakes and streams, or in man-made reservoirs and canals. Water transportation generally demands a relatively smooth terrain and a productive tributary area. In North America, the major navigation resources lie in the Great Lakes-St. Lawrence system, the Mississippi river and its branches, and the river systems of northwest Canada.

2. Soils.—Soils are classified in many ways, according to their colour, texture, origin and development, etc., but most significantly, according to the uses that can be made of them in agricultural production. A soil is valuable to man only in the light of its usefulness in producing a valuable commodity. This kind of perspective is necessary if we are to understand why, in North America, the best soils are those that can be made to successfully produce specific annual crops, especially the grain crops and cotton, which are of great importance in man's existence. Soils that produce only trees, grass or weeds, on the other hand, are usually considered less desirable, regardless of the lushness and vigour of their vegetation. Therefore, the quality of a soil is judged by its food-producing capacity, and if, in the course of human progress, this need changed, so would soil evaluations.

The geography of North American soils is most easily approached through the location of native vegetation, the dominant feature of which is a large, centrally located grassland region that is roughly triangular in shape, with apexes lying near the cities of Chicago on the east, San Antonio (Texas) on the south, and Edmonton (Alberta) on the north, and which has the richest soils of the continent. To the west and southwest lie the less fertile dry-land soils of the western United States and northern Mexico, which were formed under a vegetation cover of shrubs and related plants. To the north, northwest and east lie the less-productive soils of the areas that were originally in forest; and beyond them in the north are the generally infertile soils of the tundra. Only in the great central grassland did nature provide the physical environment necessary to form soils best suited for modern crop production.

The relative infertility of soils in both the dry regions and the humid forested regions is attributed to both climatic conditions and the characteristics of the parent material (rock) from which soils are formed. Limestone and its associated sedimentary rocks generally provide soils with minerals needed by grains and other annual crops. Soil-building materials in the central grassland region of North America generally contain those minerals, which were brought to the area mainly by (1) continental glaciers, in the area generally north of the Missouri and Ohio rivers; (2) streams of running water, in a broad belt lying immediately east of the Rocky mountains; or (3) wind, in scattered areas generally near the southern margins of the glacial deposits. In the southern portions of the central grassland area, much of the native surface rock has a high calcium content and is disintegrated into soils having these same general characteristics.

Outside the grassland region, where climates are either colder, drier or more humid, poorer soils usually occur. In the humid areas, deterioration is attributed to the removal of soluble minerals (especially nitrates, potash and phosphate) by heavy rainfall and the percolation effect of ground water, so that those minerals are available only to deep-rooted plants such as trees and vines. In the cold and dry regions poor fertility is due to lack of humus, the sparseness of the vegetation and consequent lack of annual contribution of vegetable matter such as roots, leaves and branches to the soil. Soils deficient in humus generally are unable to store moisture near the surface and thus cannot support shallow-rooted vegetation such as the grain crops and cotton. Mineral deficiencies of humid-climate soils may be offset considerably by the application of fertilizers; and water deficiencies in dry soils may be overcome by irrigation. Both these procedures provide good examples of the ways in which man can adapt his natural environment to his better advantage.

The foregoing describes only the very general features of soils geography in North America. Locally, there are many small areas where a combination of good parent materials and a favourable climate have produced soils of marked fertility. In the humid areas of the southeastern United States, as well as in Mexico and Central America, favourable materials often appear in the alluvial flood plains of major streams, the deposits of basaltic lava from nearby volcanoes and other fissures, and local occurrences of limestone. Soils derived from lava occupy many of the most fertile valleys of southern Mexico, and limestone soils are prominent in Cuba.

In the humid tropics, the river valleys, deltas and basins that can accumulate new (and unleached) minerals brought as alluvium from lime-rich upstream sources nearly always have the richest soils. In dry areas, the best soils usually occur in catch basins where water storage is sufficient to support considerable amounts of humus-giving vegetation. (*See* also SOIL.)

3. Minerals.—Most of the world's mineral wealth is taken from rocks that appear at or near the earth's surface. A few are derived from the waters of the sea, or from the atmosphere, but their quantities and economic importance are small. Among the great families of rocks, sedimentary types are the main sources for the production of the mineral fuels (coal, petroleum and natural gas), as well as most of the building stone, many kinds of rare earths and a few of the metals. It is from the other great families, the igneous and metamorphic types, however that most of the ores, the metal-bearing rocks of modern industrial civilization, are taken. The general distribution of the three kinds of rocks may therefore be used to identify areas in which these three great classes of minerals, the fuels, the metals and the other nonmetallic types, may be found.

Large areas of North America were occupied by ancient seas during geological periods when the mineral fuels were being formed with sedimentary rocks. The sedimentary regions include nearly all of conterminous United States, except for relatively small sections adjacent to the Atlantic and Pacific coasts as well as most of western Canada, Alaska and northern Mexico and large areas in the West Indies and beneath the Gulf of Mexico and Caribbean sea. Changes in the earth's crust, associated particularly with the appearance of the Rocky mountain system in the western portions of the continent, caused much of the sedimentary surface to be folded, broken, uplifted and in large part removed by erosion in areas affected by that major geological disturbance. Volcanic fires probably destroyed large amounts of fuels that were contained in sedimentary rocks, but at the same time, aided by the tremendous pressures present in the disturbance seem to have created favourable conditions for the concentration of metallic minerals into beds, veins and other deposits to form rich mineral-bearing rock. This process was frequently aided by the percolation of water through newly exposed rocks. These are believed to be the general circumstances under which the mountainous sections of western North America became the continent's leading source of ores, with the notable exception of iron.

Iron is mostly obtained from rocks that lie in the Canadian shield region near the margin of a much older mountain mass, whose interior rocks were long since exposed when the surface was removed by continental glaciation. These igneous and metamorphic rocks, which occupy most of eastern Canada and portions of the adjacent United States, are also important sources of nonferrous ores. Mines in the area of the Canadian shield, together with those in the Canadian Rocky mountains, provide a major element in the Canadian national economy. In Mexico the most important nonferrous metal is silver and in the western United States it is copper. Large reserves of iron ore occur in both areas, and there are many lesser metals, such as gold, silver, lead and zinc, much of which occurs in complex ores which yield several nonferrous metals. Metamorphosed and folded rocks in northern Arkansas yield bauxite for aluminum, and similar formations in Alabama yield iron ore for the Birmingham steel industry. Southeast Cuba also produces iron ore.

Outside the ore-producing areas lie the great sedimentary basins that extend from the Arctic ocean, on the north, southward through the middle of the continent, to the highlands of northern South America. There are produced most of North America's mineral fuels. It is of considerable significance that most of the continent's coal and a very considerable fraction of its petroleum and natural gas are produced near the margins of these sedimentary basins, where much folding and faulting was experienced in the formation of mountains. These crustal changes often had the effect of compressing coals into harder and more valuable fuels, and forming "traps" for the underground accumulation of petroleum and natural gas. Drilling of wells to great depths has shown that these crustal deformations often occur at considerable distances from present or former mountains, but the tendency for coal, petroleum and natural-gas production to transpire most prominently near the margins of the sedimentary basins is nevertheless a readily observed geographic fact.

Other minerals occur in almost endless variety. Some, such as sand, gravel and the stone that is crushed for use in concrete work, are found almost everywhere, but are of limited value, expensive to ship, and are mined only if a market exists. Others, such as gold and uranium, are extremely rare, and so valuable that they are likely to be mined wherever they are found. Thus, many communities in North America are connected with some sort of mining or related activity, but centres, where mining is the dominant element in the local economy, occur only where favourable conditions of geological occurrence and location in relation to markets are present.

4. **Land Use.**—Economic development of North America has been held within relatively narrow geographic limits by the character and spatial distribution of the resources described above. All such developments must be considered, however, not only in the light of available resources; but also as a consequence of the aspirations and productive capacities of the people who inhabit the continent.

The broad facts of land utilization include agriculture, manufacturing and trade, but the simple facts of economic development in North America indicate that less than one-fifth of the productive activity is concerned directly with the resources of nature and the raw materials that are extracted from the land, such as crops, minerals, fish and timber. The remaining four-fifths of the productive effort is devoted either to further refinement of natural materials that have already been transformed into manufactured goods, or to the rendering of services that satisfy human wants directly. In North America, the latter type of production is generally more important than the former, which is concerned with goods.

An understanding of the relative importance of the two kinds of production is vital to an understanding of patterns of land utilization in North America. In general, these considerations seem to indicate that conditions surrounding resource utilization and the production of raw materials may be expected to account for the location of only a minor fraction of the total productive activity and that the location of the remainder must be accounted for in some other way. In other words, there is no reason to expect the spatial distribution of production to bear any specific resemblance to the distribution of that continent's resources.

Nearly one-half of all the goods and services are produced in a relatively small area that lies generally south of a line drawn westward from Quebec in Canada, to Minneapolis in Minnesota and thence south to St. Louis, Mo., and eastward to Baltimore, Md. Other areas of major importance appear in southern California and in the southern portions of the central plateau of Mexico. These regions, which together constitute less than one-tenth of the land area of the continent, but which account for more than one-half its total production of goods and services, do not appear prominently on any map of raw-materials production. Their resources apparently are not ordinarily considered in surveys of the type undertaken here.

The most basic preliminary observation may well be that most of the working hours of the people of North America are spent in rendering services rather than in changing the form of goods. Fundamentally nearly all services must be rendered while in close proximity to the customer, as in the case of barbers, physicians, teachers, salesmen and many others. Thus it appears that the most important factor in the location of services is the presence of considerable numbers of people who have an appropriate volume of money and a desire for those services. But what brings these people to an area? The problem is further complicated, as frequent research shows that many types of manufacturing are attracted by potential customers; this provides a basis for understanding why the location of only a minor fraction of these productive activities can be accounted for in terms of the location of natural resources. What apparently happens is that in the early stages of production, the location of activity is rather closely adjusted to the existence of local resources. Raw materials leaving the farms, forests and mines, whose locations are adjusted to the presence of those resources, may be subjected locally to a small amount of elemental processing, such as canning, sawing or milling; but most of the work of increasing their usefulness is likely to be carried on in some distant location nearer markets for the finished products. These manufacturers, together with others in the region, attract additional service employees, and the ultimate outcome of this concentration appears in the great industrial cities and metropolitan regions.

The locations of markets for the continent's products must be considered in any explanation of the distribution of land uses. Historically, the greatest concentrations of population and productive activities first appeared at the western termini of the North Atlantic trade route to Europe, over which exports from Canada and the United States reached their most important world markets. Seaport cities with good harbours grew and prospered as this export trade expanded, and, in the process, developed large import, financial, industrial and other related economic interests. With the westward movement of population and production, these same types of activities were attracted to cities nearer those markets, and they sought sites mainly along major transportation routes, notably the Great Lakes-St. Lawrence waterway and the major trunk-line railroads. Climate and raw materials were also important in the rise of other metropolitan centres such as Los Angeles and the Federal District of Mexico. Many analysts believe that, in the long-run future, favourable concentrations of resources will come to outweigh historical factors in determining the location of economic activities.

By mid-20th century, regional planning (*q.v.*) in North America, demonstrated by the TVA, for large areas of like characteristics, grew out of a series of initiatives. Politically directed, it is based mainly upon the social and natural-resource structure, and economically seeks the fullest development of local resources and skills. Natural resources are also discussed in *The Economy* sections of articles on the various countries. (H. H. McC.)

III. ANTHROPOLOGY

1. **Ethnology.**—The American Indians had their origins in Asia, and are basically Mongoloid in physical type. The new world may be dismissed as the home of fossil human development

because no fossil progenitors have been found and the evolution of the primates clearly occurred in the old world. The date of arrival in North America as yet has not been accurately established but occurred sometime during the last glacial period. (*See* ARCHAEOLOGY: *Prehistory: The New World Prior to Urban Civilization.*)

Culture.—The earliest incomers to the new world possessed a series of traits that were relatively ancient and were shared with most cultural groups in the old world. These included the use of fire and the fire drill; the domesticated dog; stone implements of many kinds; the spear thrower, harpoon and simple bow; cordage, netting and basketry; crisis rites and shamanistic beliefs and practices. Important traits lacking in the new world but known in the old world included various significant domesticated animals, plants and artifacts—including cattle, sheep, the goat, pig, horse, camel and reindeer; wheat, barley and rice; the wheel and the plow; iron; and stringed instruments. The higher cultures of the new world, all possessing enough advanced traits to warrant calling them civilizations, were spread from the valley of Mexico south to Peru. The economic base of the American high cultures was horticulture with maize, beans and squash the staple crops. These crops were cultivated from the St. Lawrence river in the north to the Rio de la Plata in South America. The plants were tended by hand, using only the simple digging stick or a hoe.

Middle America was a region of towns, therefore, of higher political organization, and in Mexico and Peru of considerable empires. The intellectual achievements, dependent upon the existence of a priesthood, culminated in the mathematical and calendrical systems and in an incipient system of writing employed by the Maya and Aztec. (*See* ARCHAEOLOGY: *Mesoamerica;* AZTEC; MAYA INDIANS; MIDDLE AMERICA.)

The question of whether or not the advanced techniques used by the higher cultures of America were independent inventions or the result of contact and borrowing from the old world is still debated. No evidence is presently available to document the possibility of old world contact, and until such evidence is forthcoming the most probable conclusion is that of independent invention. Analysis of the known intellectual achievements shows them to be unique. The Maya devised position numerals and a sign for zero, but their system of numeration was vigesimal and they were using the system several hundred years before the sign for zero was invented in the old world.

Culture Areas.—According to Harold E. Driver and William C. Massey there were at the time of European contact about 240 different tribal entities in North America; these were divided into a number of groups or culture areas. (*See* fig. 3.)

Classification of groups of tribes into culture areas is an attempt by anthropologists to reduce the complexity of cultural types to fewer, meaningful units. Ideally, a culture area is a geographic region inhabited by tribes that resemble each other in the totality of culture traits more than they resemble other tribes. Because of the variable diffusion of traits, however, there are often considerable differences among tribes within a culture area. In the Plains culture area of *c.* A.D. 1800 there were fully nomadic bison hunters, semisedentary hunters who practised some agriculture, and sedentary village farmers. The following classification is somewhat arbitrary but necessarily so in a brief summary. Nine culture areas are listed and indicated in fig. 3. The more important or better-known areas are described in separate articles and in *Prehistory and Archaeology* below. The main areas are: (1) arctic coast (*see* ESKIMO); (2) subarctic, which includes both Athapaskan and Algonkian forest hunters (*see* CANADA: *Native Peoples;* ATHAPASKAN; ALGONKIAN TRIBES); (3) northwest coast; (4) basin-plateau, the area of somewhat marginal cultures in the intermontane west; (5) California; (6) southwest, including northern Mexico (*see* PUEBLO INDIANS); (7) plains (*see* PLAINS INDIANS; SIOUAN INDIANS); (8) eastern woodlands (*see* MUSKOGEAN INDIANS; IROQUOIS); (9) Mesoamerica (*see* AZTEC; TOLTEC; ARCHAEOLOGY: *Mesoamerica*).

Indian Population.—The number of Indians in North America at the time of Columbus was estimated by A. L. Kroeber at about 1,000,000 north of Mexico and about 5,000,000 in Mexico and Central America. Numbers fell significantly after contact with the

FIG. 3.—CULTURE AREAS OF ABORIGINAL NORTH AMERICA

Europeans, mainly because of increased warfare and some diseases such as measles and smallpox which were fatal to Some tribes became extinct; others merged and lost their Since about 1910 the Indian population has steadily increased, some, like the Navaho (*q.v.*), were more numerous in the than in aboriginal times.

2. Languages.—The outstanding characteristic of American Indian languages is their diversity. There are more than 60 guage families in North America, comprising over 500 languages but these have been reduced to a smaller number of superstocks Edward Sapir and others. No genetic relationship to any language group in the old world has been fully demonstrated as yet may conclude from this that the ancestors of the Indians left old world so long ago that any relationship was lost through guistic change. (*See* AMERICAN ABORIGINAL LANGUAGES, TRAL AND NORTH AMERICAN LANGUAGES.)

3. Physical Anthropology.—American Indians are not form in physical type but are basically Mongoloid. They some distinctive traits, including reddish-tan skin colour nounced cheekbones, prominent noses, thin lips, well-developed chins and heavy faces. Hair and eye colour is uniformly dark cept in cases where admixture with Europeans has occurred. of the classic Asiatic Mongoloid physical traits, such as epicanthic eye fold and fatty cheeks, are generally absent in the new world populations, excepting the Eskimo.

IV. PREHISTORY AND ARCHAEOLOGY

North American prehistory is a complex and variable record man's adaptation to the various continental environments and

his developing culture over more than 25,000 years. The earliest records of the peopling of North America are scanty and it is difficult to characterize their culture beyond calling it a hunting and gathering economy with simple stone and bone tools. The earliest remains were found in the western United States, Mexico and South America. First settlers seem to have crossed the Bering straits region from Asia during the expansion of the last major Pleistocene ice sheets. As the great ice sheets developed and expanded they not only covered major land areas in the northern hemisphere but they also brought considerable areas of the continental shelves above sea level. In the arctic this provided a tundra coastal plain across which man could move from Asia to North America. The amount of the earth's moisture incorporated into the ice probably lowered the sea level hundreds of feet. Asia and America were thus not separated by the gradual rise of the sea until about 9,000 years ago; likely sites of the earliest migrants are now below sea level.

Some authorities believe that the culture of the earliest inhabitants is represented by crude scrapers shaped by percussion, choppers, knives and a few bone perforators. Such tools are equated with an eastern Asiatic mid-Pleistocene complex which lasted well up into the Late Paleolithic when more advanced and varied industries were developed in western Asia and Europe and spread east and northeast.

The Americas were the last major land mass, with the possible exception of Australia, to be occupied by prehistoric man, who first had to develop the cultural equipment to exist in the arctic area. Once this adjustment was made, during the Würm-Wisconsin glaciation he was able to move, by way of the nonglaciated areas, into the Mackenzie basin and into continental United States. The time of the initial dispersal into North America is estimated to be between 25,000 to 35,000 years ago. Some period of time should be allowed for the gradual spread of the first Americans throughout the varied environments during the retreating phase of the Wisconsin ice. There were significant displacements of vegetational and climatic zones to the south during this period.

1. Early American Hunters.—In contrast to the sparse knowledge of the period from 25,000 to 10,000 years B.C. is the considerable body of data on the cultural pattern of primarily hunting people whose remains were found from the Pacific to the Atlantic and from the Gulf of Mexico to the borders of the last major stand of the Pleistocene ice sheets in the north central United States between 10,000 and 8,000 years B.C. (*See* fig. 4.) In spite of regional differences in detail there was a remarkable similarity in the industrial complex of these people. They lived in a variety of environments, from mountain passes and valleys in the west to the then better-watered grasslands of the plains, and the varied forest and park-land environment of the eastern woodlands. Their projectile points (a variety of fluted forms), scrapers, perforators, knives and a variety of bone tools indicated that one of their major food supplies came from animals, whose hides provided clothing. In the western plains and the southwest they hunted such extinct North American animals as the camel, ground sloth, tapir, mammoth and horse.

FIG. 4.—APPROXIMATE BOUNDARIES OF EARLY AMERICAN FLUTED BLADE HUNTERS AND AREA OF DESERT CULTURE IN NORTH AMERICA AT 8000 B.C. (IMPORTANT SITES AND CULTURE GROUPS OF PERIOD SHOWN)

In the Great Lakes area of the eastern woodlands they may have hunted mastodon, but other commoner animals such as the elk and deer presumably formed the bulk of their meat diet. Some of their bone and wooden tools were probably used for working and ornamentation. These early hunters had temporary shelters and moved about as small bands in search of game. Their presence was known primarily from "kill" sites and a few areas indicated temporary occupation along streams or lakes. Their physical type is not clearly known but it was related to that of the eastern Asian Late Paleolithic population and is less Mongoloid than many groups of American Indians of the historic period.

2. The Desert Culture.—In the western United States from Oregon to northern Mexico and from the Pacific coast to the eastern foothills of the Rocky mountains there was a distinctive cultural adaptation to the dry, upland environment. From before 8000 B.C., to the historic period in some areas, there existed a desert culture type (*see* fig. 4–6) that may be viewed in a general way as an equivalent to the Archaic level in the eastern United States.

The Desert culture people lived as small bands of wandering seasonal food gatherers, collectors and hunters. They ate a wide variety of animal and plant foods and developed techniques for small seed harvesting and processing. Their best-known habitations were caves and rock shelters. Found preserved because of the dry environment were twined basketry, nets, mats, cordage, fur cloaks, sandals, wooden clubs, digging sticks and in some instances even desiccated bodies. They had the spear thrower, with darts of pointed hardwood or with points of flint and later of obsidian. Their rough stone implements were shaped by percussion and consequently many of their choppers and scrapers had a Paleolithic appearance. When these were discovered on open sites where organic materials were not preserved they gave a false impression of great antiquity. Their projectile points however showed excellent craftmanship and followed continent-wide styles. Milling stones and handstones were a prominent feature of Desert culture sites. The dog, another migrant from Asia, was known by about 4000 B.C., and was also found at this time in eastern Archaic sites.

3. California.—On the far west coast in California, the marked variety of geographical situations developed a number of regional complexes dependent upon intensive exploitation of the local resources. None of these were agricultural, although population density in some of the more favoured areas appears to have approached that of the early farming cultures of the southwest and east. In the southern desert area the people subsisted upon plant seeds and small game with utilization of crude flint tools, grinding stones and (later) arrowheads, the main implement forms recovered. In the mountainous area of the state and in the better-watered central areas, larger game animals such as the elk and deer, supplemented by acorns, fish and birds, were the major food supply. By at least 2000 B.C., in this central area, the utilization of the local resources plus cultural intrusions from the north resulted in the adaptation that only changed in minor details up to the historic period. The coastal groups from north to south depended upon the sea for their food supply, some subsisting mainly on shellfish, some on sea mammals, others on fish and still others a mixture of all three. All of these may be said to be on an Archaic level of development, but they are probably better viewed as developed regional variants of the Desert culture. The intensive regional adaptations probably account for the linguistic variability and many small tribal groups found in California at the historic period.

4. Northwest Coast.—In the north Pacific part of the United States and in western British Columbia, some of the early sites of the hunters had fluted blades, crude choppers and cutting tools. Between 9000 and 7000 B.C. there were varied economic activities but with an emphasis on hunting. By about 8000 B.C. some sites showed a strong orientation toward salmon fishing, particularly during the salmon runs, and tended to emphasize the use of bone and antler tools. The burin, a chisellike bone working tool, was found in these levels along with prepared cores and blades. During the postglacial warming period which culminated between 3000 and 2000 B.C. the inhabitants of the dryer areas without permanent streams took on more of the traits of the Desert culture to the south, while others turned toward riverine fishing and marsh resources or to food from the sea. In the first millennium B.C. the Marpole complex, a distinctive ground slate complex, was known in the Fraser river area with basic resemblances to the northwest coast historic culture in maritime emphasis, woodworking, large houses and substantial villages. The emphasis on ground slate and woodworking tools is like that in the eastern boreal forest Archaic, and recalls similar emphasis in northwestern Siberian early Neolithic cultures. Another culture trait of ultimate Siberian origin which came to the British Columbia area shortly after A.D. 1 was a second introduction of the polyhedral core and blade, regarded as a distinctive part of the Arctic Small Tool tradition. In most of the areas of the northwest coast clear indications of the beginnings of the historic cultures were not known until about A.D. 1300.

5. The Eastern Archaic.—In the eastern woodland area, partly as a result of the variety of forest environments, climatic differences and physiographic features, there developed a series of regional adaptations to local food supplies. The change from the primarily hunting economy of the early American hunters was gradual and is clearly seen in slowly evolving projectile point and other implement changes. The pattern of life became one of mixed hunting and collecting, with some groups by 6000 B.C. developing a taste for riverine and coastal living with abundant fish and mollusk resources to supplement the vegetational products such as acorns, seeds, berries and tubers.

During the long eastern Archaic from 8000 to 1500 B.C. regional diversification was developed and strong continuities or traditions may have been seen in local areas, some of which are named in fig. 5. These reflected both the greater exploitation of regional environments through generations of experimentation and greater familiarity with the resources, and the resultant resistance of the environmentally conditioned culture to group mobility. It was during the Archaic that significant early linguistic diversification probably occurred, and during which varieties of physical types developed.

The typical Archaic house was a small circular structure with wooden posts for the wall and roof supports. The covering was probably bark. Cooking was done in the open by boiling in containers of wood, bark or hides or by baking in pits or by roasting and grilling. Identification lists of mammal, fish and bird bones from Archaic sites read like a listing of the early historic fauna. Various game-gathering devices, including nets, traps and pitfalls, were used besides the spear and dart thrower. Fishhooks, gorges and net-sinkers were known, and in some areas fish weirs were built. River, lake and ocean mollusks were consumed and their discarded shells formed large shell middens near the favourable collecting areas. The deep shell middens have preserved a record of stylistic change and the introduction of new industries to the Archaic economy. While relatively little of the vegetal foods were preserved, nut hulls are known and the grinding and pounding stones attest to this type of food supply. Probably a great many native roots, berries, fruits and tubers known as used in the early historic period were incorporated into the diet during the Archaic. Also the extensive list of plant medicines recorded by the early colonists were probably a part of the primitive Archaic pharmacopoeia.

The large variety of chipped-flint projectiles, knives, scrapers, perforators, drills and adzes reflect regional styles and changes during the long Archaic period. The Late Archaic was distinguished by the gradual development of ground and polished, grooved stone axes, celts, pestles, gouges, adzes, plummets and forms attached to the spear thrower. This was a reflection of a growing versatility in the technology and economy. Trade and exchange are also known from the distribution of native copper implements from the Michigan-Wisconsin area to as far south as Louisiana and Florida, and the finds of southeastern marine shells as far north as the upper Mississippi-Great Lakes area. An extensive system of trails and water routes was probably in existence during the Late Archaic.

The great boreal forest zone of spruce, fir and pine which now runs from New England and the maritime provinces of Canada

FIG. 5.—HUNTING AND GATHERING CULTURES IN NORTH AMERICA, ABOUT 3000 B.C.

westward to the Canadian plains and the Mackenzie valley gradually acquired its present distribution following the retreat and melting of the Canadian ice cap. Its present distribution was reached by about 2500 B.C. This forest zone is not well known archaeologically because of its inaccessibility and the absence of modern settlements. The forest cover and the climate had a limiting effect on the cultural development and on the general pattern of hunting and fishing. These efforts were supplemented by some use of plant material. The early historic Algonkian tribes of the area from the Naskapi on the east to the various Cree (*q.v.*) and Ojibwa (*q.v.*) bands to the south and southwest of Hudson bay were the cultural descendants of the cultural adaptation which took place in this forest zone.

In the upper Great Lakes area the Old Copper culture has a special interest because copper implements and weapons were made from the native copper of the Lake Superior basin. This culture appeared about 3000 B.C. and lasted about 2,000 years. It was a northern expression of the Late Archaic. Its tools and weapons, particularly in the adzes, gouges and axes, clearly indicate an adaptation to the forest environment. In the area south of James bay to the upper St. Lawrence about 2000 B.C., there was a regional variant called the Laurentian Boreal Archaic and in the extreme east the Maritime Boreal Archaic. In this eastern area, slate was shaped into points and knives of similar form to the copper implements to the west. Trade between the eastern and western areas could be recognized and this evidence, along with general similarities of the culture, suggests that water transportation by canoe was known at this time.

Along the southern border of the central and eastern boreal forest zone between 1500 and 500 B.C. there developed a distinctive burial complex, reflecting an increased attention to burial ceremonialism. These burials, many including cremations, were often accompanied by red ochre, caches of triangular blanks, fire-making kits of iron pyrites and flint strikers, copper needles and awls, and polished stone forms. The triangular points of this complex may have represented the introduction of the bow and arrow from the pre-Dorset and Dorset cultures east of Hudson bay. The earliest Woodland pottery appeared in the Great Lakes area about 1000 B.C. It is another of the culture traits derived from northeastern Asia and across northern Alaska to northwestern Canada. The route by which it reached the Great Lakes is not known.

6. The Plains Archaic.—In the western plains from about 8000 to 3000 B.C. the fluted blade points were no longer made, and many styles or types were produced which were identified by such local names as Plainview, Angostura, Milnesand, Agate Basin, Scottsbluff and others. These minor varieties of dart and spear point and their primarily hunting culture may be included in the term Plano. The Plano complex or culture type was a direct descendant from the fluted blade early American hunters. Their primary game animal was the bison, for the larger animals of the preceding period had died out or were exterminated.

The stone complex associated with the Plano hunters was markedly similar from site to site over a considerable period of time during which the climate became increasingly warmer and until the major warm period was reached about 3000 to 2000 B.C. As the climate moderated, peoples of the Late Plano complex moved north into Saskatchewan and Alberta (*see* fig. 5) with the grazing game animals, and by 3000 B.C. had reached the arctic tundra zone in the Northwest Territories of Canada at Grant and Dismal lakes and Great Bear river. Important elements of this culture also moved east in the Mississippi valley and western Great Lakes area. Many of the sites of this culture type were kill sites with abundant bison bones which accounted for the number of implements and tools associated with hunting and leather working. In the tundra zone the major game animal was the caribou. However, some choppers, pounders and milling stones were known, and living sites indicate that the Plano economy was not as limited as it may seem.

7. The American Arctic.—There is little evidence of man in the American arctic in the period between 25,000 and 10,000 years ago, and only scattered finds and no excavated sites of culture which could have occupied the period between 8000 and 5000 B.C. There were some finds of fluted blades and of Plano forms which probably reached Alaska via the Mackenzie corridor, and also knives and graving tools of immediate Siberian origin which may have been of this same antiquity. In the Seward peninsula and in the Brooks range there were indications of a land hunting and to some degree sea-mammal hunting group which may have been related to some of the boreal forest cultures to the south. Their estimated time period would be from 5000 to 3000 B.C. Interior Alaska and western Canada are not well known archaeologically.

Between 3000 and 2000 B.C. the Arctic Small Tool tradition developed in northwestern Alaska. It was based on the hunting of caribou and other tundra animals along with some dependence on sea mammals. This culture included some elements from the northern spread of the Plano hunters to northwestern Canada but was primarily derived from northeastern Asia. It gradually spread eastward in the Canadian tundra to the northwest and northeast side of Hudson bay, into extreme northeastern Canada, and to western and northern Greenland. This eastern spread was accomplished by 1000 B.C.

In the dominant culture centre of the arctic, the Bering sea area, there developed from 500 B.C. to A.D. 500 a number of cultures identified as Paleo-Eskimo whose primary adaptation was that of sea-mammal hunting. These cultures blended elements of the earlier Arctic Small Tool tradition with pottery and other traits from the Lena valley, and with elements from cultures which developed along the northeastern Siberian coast. The sea-mammal hunting economy gradually moved eastward as the Thule culture and became the economic base for most of the Eskimo groups in the central and eastern coastal arctic by the time of European expansion into the area. Another branch of the sea hunting culture was found in southeastern Alaska where it came into the historic period with the Aleut and western Eskimo.

8. Early American Planters.—Primitive agricultural practices began in Mexico by 6000 to 4000 B.C., and by approximately 2000 B.C. were known on the northern fringe of the Mesoamerican culture area. Maize was not the only crop plant, for gourds, squash, peppers, cotton and varieties of beans were also domesticated. Maize was grown in the southwestern United States by 2000 to 1000 B.C. but most of the other domesticates did not arrive until just before and after A.D. 1. The early introduction of maize in the southwest had no marked effect on cultural development, and the existence of pottery, storage pits, domestic houses with semisubterranean floors and lateral entryways were not known until about A.D. 1. These houses had wood uprights for walls, central roof supports, radiating beams and wattle and daub plastered walls. Ceremonial houses were much larger than the domestic homes and they show no evidence of everyday occupational debris. Two important cultural traditions, Hohokam and Mogollon (*qq.v.*), developed in southern New Mexico and Arizona (*see* fig. 6). These two traditions, developed from similar late preceramic phases of the Desert culture, were influenced by similar traits from northwestern Mexico but evolved into different complexes as the result of differing environmental conditions and subsequent cultural accretions from Mexico (see *Southwestern Village Farmers* below). The early Anasazi (*q.v.*) culture expressions called Basket Maker of the Four Corners area (namely northwestern New Mexico, southwestern Colorado, southeastern Utah and northeastern Arizona) were primarily stimulated through contact with Mogollon populations to the south. These early small settlements were the first village agriculturalists in the southwest.

On about the same time level were the first village cultures of the east which, however, developed an elaborate burial ceremonialism. The cultural expressions of the east known as Early Woodland were in some part a development from Late Archaic complexes and in part stimulated by new techniques and concepts which came into the area from a number of directions. Woodland pottery was introduced from northeastern Asia about 1500 B.C. and burial mounds made their first appearance slightly later (*see* MOUND BUILDERS). It is believed early agricultural activities began about 1000 to 500 B.C. although clear evidence for this in the humid east is not yet available. It is not certain whether agriculture was introduced directly from northeastern Mexico or by way of the southwest. The best-known culture types were

Adena, which began in Early Woodland in the Ohio valley, and Hopewell (*q.v.*), which marked the beginning of Middle Woodland in the northern Mississippi and Ohio valley. Both these cultures were stimulated by the arrival of concepts and practices from Mexico that were recognized by the production of figurines, ear spools and certain ceramic innovations such as the negative painted pottery. Late Adena and Hopewell reached their peak of development and expansion during a relatively warm minor climatic phase between 200 B.C. and A.D. 200, which allowed a northern spread of this early agricultural economy into Wisconsin and the southern half of Michigan.

The village areas of Adena and Hopewell varied in size from ½ ac. to about 5 ac. Circular and oval houses for single family occupancy were built of wood and bark, and storage and refuse pits were excavated in the village area. The villages were usually located in major stream valleys adjacent to, or on, easily tilled alluvial flood plains. The earthwork patterns of Ohio valley Adena and Hopewell were placed in or near the village and are ceremonial expressions not clearly understood by archaeologists. The size and complexity of these geometric earthworks and the accompanying burial mounds compare favourably with those of northwestern Europe during the Bronze and Early Iron ages. Extensive trade and travel by these people was proved by raw materials brought into the Ohio-Illinois areas from the Rocky mountains, North Dakota, Lake Superior, the southern Appalachians, and the Gulf and South Atlantic seacoasts. Ohio, particularly, served as a distributing centre for ceremonial goods and special products over a wide area in the eastern United States. These cultures were the first indications of craft specialization and of social stratification.

FIG. 6.—DISTRIBUTION OF EARLY AMERICAN FARMERS AND CONTEMPORANEOUS GROUPS IN NORTH AMERICA ABOUT A.D. 1

There is a clear evidence of cultural regression between A.D. 200 and 700 in the north-central United States following the Hopewell expansion and florescence. This is attributed to a minor cold phase which did not allow a continuation of agriculture in this area under the techniques then current. While there was concurrent change in the south, this did not take the form of a lowering of the cultural level.

9. Eastern Village Farmers.—The last major cultural development in the eastern United States is called Mississippian because its primary centre was in the valley of the Mississippi river, and along its major tributaries, and in the southeast. This predominantly agricultural complex was a marked cultural advance over earlier stages in the east. Its initial growth and expansion was at approximately the same period (A.D. 700–1200) as that of the southwestern Anasazi complex. (*See* fig. 7.) The initial growth was along the Mississippi between modern St. Louis and Vicksburg. It was stimulated by the introduction of concepts, religious practices and improved agricultural procedures from northern Mexico, which resulted in a sedentary societal organization. By A.D. 1000 large villages were in existence with subsidiary villages and farming communities nearby. Regional specialized production in pottery, projectile points, house types and other utilitarian products reflected the tribal groupings of the period. The outstanding feature of this culture type was the earthen temple mound, which served as a raised platform on which the major community buildings were placed. These council houses and "temples" served as the political and ceremonial centres. The platform mounds were placed on the sides of a central plaza which served as a ceremonial centre for the tribal community during the important recurrent functions or during times of crisis. The more permanent buildings, both family and community, were of wattle and daub construction, usually rectangular in floor plan. In some areas large, circular charnel houses received the remains of the dead, but burial was normally made in large cemeteries, or under the floors of dwellings. The size of the ceremonial tribal centre varied from 10 ac. to 100 ac. Important household industries involved the production of mats, baskets, clothing and a variety of vessel forms for specialized uses. Food surplus was kept in ground storage pits and in storage cribs above the ground.

One of the more striking developments was the production of ceremonial costumes and ornaments, for use in the religious ceremonies that were conducted by an organized priesthood with a well-established ritual. The religious symbolism spread throughout the Mississippian complex and a number of centres of production of specialized ceremonial items are known. Other innovations were walled fortifications with timber palisades and bastions surrounding the village, which reflected an increase in intergroup aggression and a tendency, continuing into the historic period, toward the development of confederacies. The intergroup conflicts apparently were primarily quests for prestige and revenge instead of means of territorial expansion or economic control.

Many of the tribal groups of the early historic period parts

pated in the Mississippi culture. Among these were the Caddoan-speaking tribes of Arkansas, Oklahoma, Texas and Louisiana (*see* CADDO); the southern Siouan Osage and Quapaw (*see* SIOUAN INDIANS); the Natchez, Choctaw, Chickasaw and Creek (*qq.v.*), who were Muskogean-speaking (*see* MUSKOGEAN INDIANS); the Cherokee (*q.v.*) of the Iroquoian linguistic family (*see* IROQUOIS); and the Algonkian-speaking Illinois, Miami and Shawnee (*see* ALGONKIAN TRIBES).

Along the eastern and northern periphery, such tribes as the Siouan Catawba and Tutelo, the eastern Algonkian Powhatan and Micmac (*qq.v.*), the Iroquoian tribes of the eastern Great Lakes, and the Algonkian tribes of the forest zone south of Hudson bay and the western Great Lakes, all retained the older Woodland complex but with some indications of Mississippian influence. The extent of this influence seems to have depended on their nearness to the more advanced cultural complex, and on their ability to maintain an agricultural economy along with hunting and gathering.

There was a spread of Woodland culture during Middle Woodland into the eastern part of the plains from Oklahoma to North Dakota, with some sites, particularly in eastern Kansas, clearly forming a part of the Hopewellian complex (*see* fig. 6). Some of the Woodland traits went as far west as the high plains in Colorado. Most of the Woodland sites in this latter area were, however, Late Woodland in their relationships and probably began about A.D. 700–800. In the plains there was evidence of corn and bean cultivation during Middle Woodland, and in Late Woodland cultivation of gourds and squash. Between about A.D. 300–400 and A.D. 800 there was little occupation of the western part of the plains by agricultural people because of the relative aridity. After A.D. 800, however, Late Woodland populations had spread west to the eastern slopes of the Rockies and were in contact with eastward-moving Puebloan people. A favourable agricultural period was indicated by the marked increase in village size and in population density for the next 400 years, during which hospitable areas along major streams were occupied by various interrelated cultural groups collectively known as the plains Mississippi cultures. Part of this complex was connected to the developing Mississippi complexes to the east by diffusion, and to some degree by a migration of such groups as the Omaha (*q.v.*) and Ponca from the St. Louis area by about A.D. 1000. Some cultural characteristics such as the earth lodges with entranceways had connections into the southwest, but the major orientation was toward the Mississippi valley. Together with a northward expansion of agricultural people along the Missouri into North and South Dakota before A.D. 1200, segments of the Upper Republican adaptation were developing along stream and creek valleys west into the high plains (*see* fig. 7) but because of increasing aridity in the western area they subsequently withdrew to the east. Between A.D. 1500–1700 the high plains from New Mexico to Wyoming and in eastern Oklahoma, Kansas and Nebraska were preempted by horse-using, semiagricultural and plains Apache and Comanche (*qq.v.*). Prehistoric village agriculturalists of a plains Mississippi tradition came into the historic period as the Pawnee, Arikara, Mandan, Hidatsa, Crow (*qq.v.*) and Wichita.

10. Southwestern Village Farmers.—The southwestern village farmers were distributed from eastern Utah and southern Colorado through most of New Mexico and Arizona. The effective agricultural area varied with fluctuations in climate that profoundly affected the ability of the Indians to occupy marginal regions. While corn and some other agricultural plants were introduced from Mexico between 2000 B.C. and A.D. 1, the first village complexes, with 5 to 15 pit or surface houses, ceremonial buildings, refuse pits and pottery, did not appear until shortly before A.D. 1 in southern Arizona and New Mexico. Two of the major farming complexes began at this time: Mogollon was located in the mountainous belt of west central New Mexico and east central Arizona, while Hohokam was located in the desert area of the Gila basin of southern Arizona. The latter group depended upon irrigation for its crops while Mogollon depended upon rainfall and stream diversion over flood plains. Mogollon became the pattern of agriculture adopted by the Indian groups of the Four Corners area along with other traits from the south, and later developed into the Anasazi (*q.v.*) or Puebloan culture, the third major farming complex of the southwest.

The geographical expansion, population growth and striking development of permanent villages with multiroom and multilevel buildings came during the period from A.D. 700 to 1200, which coincided with a minor climatic period of favourable distribution of rainfall for plant growth over the entire southwest. For the same climatic reasons, there was an expansion of popu-

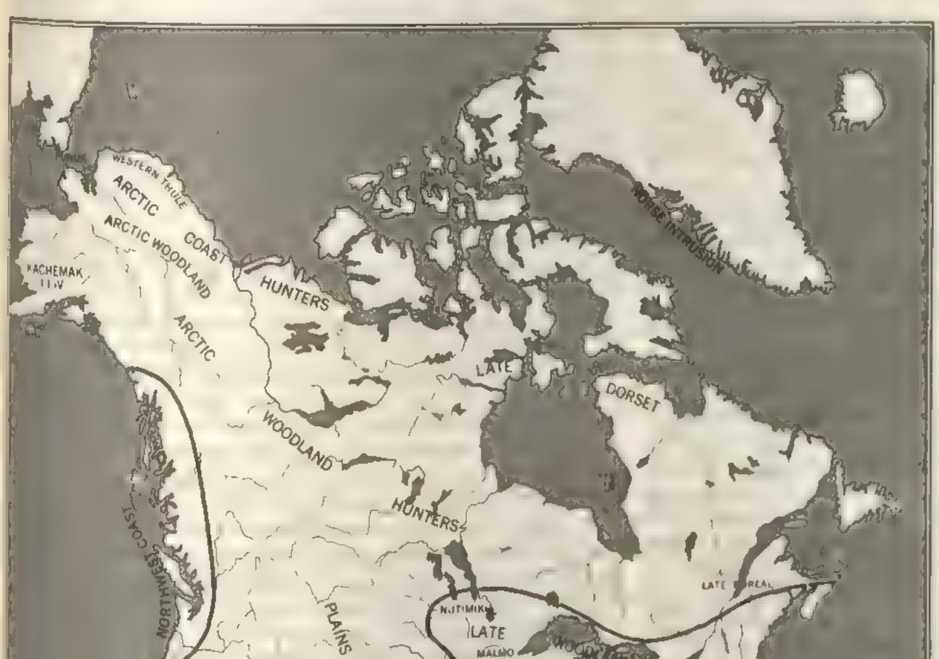

FIG. 7.—EXPANSION OF FARMING VILLAGES AND CONTEMPORANEOUS WESTERN AND NORTHERN HUNTING-GATHERING CULTURES IN NORTH AMERICA, ABOUT A.D. 1000

lation and cultural movement from central and western Mexico into northwestern Mexico. Trade and cultural stimuli then moved from northwestern Mexico into the American southwest at a time when the climate in both areas was most favourable for population and cultural growth. Indicating such cultural movement, cast copper bells, parrots, ball courts, shell trumpets, pottery vessel shapes and designs were found; they clearly reflect the transmission of religious beliefs and ceremonies. These southern influences were blended into local and regional complexes.

The Anasazi village agricultural complex had expanded by A.D. 900 to occupy northeastern Arizona, southwestern Colorado and northwestern New Mexico. By A.D. 1100 expansion had taken place into the Virgin river valley of southeastern Nevada, north as far as the Great Salt lake and northwestern Colorado, to the east into southeastern Colorado and to the Pecos and upper Canadian river valleys of New Mexico. Some of the important cultural characteristics, incorporated into the architectural plan, that identify Anasazi of this period are stone masonry, multiroom and multistory house structures and oriented kivas (ceremonial chambers). Textured and corrugated, gray cooking and utilitarian pottery and pottery with black painting on white slip are also found. During this period there was probably a development of priestly offices and of rituals and ceremonialism. The increasing population concentration in large pueblos was apparently organized into households according to lineage. Control of the agricultural activities was presumably in the hands of clan leaders who were also the priests who officiated in the rain-producing ceremonies. During this period some of the larger village populations ranged from 300 to more than 1,000 people.

Primarily because of increasing aridity there was a marked retraction of Anasazi culture between 1100 and 1300 from its northern, western and eastern limits of expansion. As a result, a concentration of the pueblos took place in northeastern Arizona, and along the Rio Grande and its immediate tributaries, and in the present Zuñi area of western New Mexico. In these favourable areas the Anasazi groups were able to maintain their societies by sand-dune farming with floodwater and some canal irrigation. The increased importance and elaboration of religious rain-producing ceremonies between 1300 and 1540 is deduced from paintings on kiva walls and from a more elaborate symbolism in pottery decoration. Polychrome painting on pottery was the major decorative technique. At this time the village houses were grouped around one or more plazas, as in the upper Rio Grande and Little Colorado areas.

The early historic and modern Pueblo Indians (*q.v.*), from the Zuñi and Hopi (*qq.v.*) on the west to the Rio Grande groups on the east, were the direct descendants of the Anasazi populations.

The Mogollon complex in its early phases from 200 B.C. to A.D. 700 consisted of relatively small villages of pit houses grouped near a large ceremonial structure. The pit houses had a round to quadrangular floor plan, sometimes with long, lateral entries. No organization of the village structures into a pattern is apparent and trash disposal was random. The dead were buried flexed, sometimes with brownish-textured, polished, red-filmed and red-painted pottery. While the initial impetus for sedentary village life appeared early in the Mogollon area there was an apparent period of cultural quiescence about A.D. 400 to 600. With the growth and spread of the Anasazi complex in the period after 700, the main flow of culture was from that area, and Mogollon villages from A.D. 900 to 1100 were a blend of local development strongly influenced from Anasazi. During the climatic deterioration after A.D. 1200 much of the Mogollon territory in southwestern New Mexico was abandoned. The western Puebloan groups of the late prehistoric period also seem to represent this blend.

The Hohokam culture of southeastern Arizona was primarily limited to main river valleys. Their agriculture was made possible by extensive irrigation canals which required intervillage co-operation. They lived in villages of scattered pit houses made of brush and mud, which were dispersed along the streams and canals. Their main settlements and major culture growth took place also during the period A.D. 700–1200. Following this for 200 years, there was a blend with Anasazi and Mexican elements and a tendency toward the construction of more compact settlements surrounded by compound walls with a few massive multiroom and two-story buildings. Some of the other distinct characteristics were etched shell ornaments, paddle and anvil shaping and finishing of pottery, red-on-buff pottery, excellent stone carvings, well-made projectile points and grooved stone axes, ball courts, small kivas, cremation, and relatively little evidence of trade and influences from northwestern Mexico. Such historic groups as the Pima and Papago (*qq.v.*) are regarded as descended from the Hohokam people.

North American prehistory presents a great variety of cultural adaptations—from the early hunting and gathering groups that initially occupied the U.S. territory and gradually moved into the Canadian area to the early historic agricultural societies and hunting, fishing peoples. The major climatic and ecological areas strongly influenced the culture types which arose from 12,000 to 3,000 years ago. Following the introduction of agriculture and associated concepts from the dominant Mesoamerican civilization there developed two important centres of farming societies, in the southwest and in the Mississippi valley. Their growth and development was arrested by the intrusion of European explorers and colonists, and North America rapidly became a part of western civilization. *See* also ARCHAEOLOGY; INDIAN, NORTH AMERICAN INDIAN, LATIN-AMERICAN; for *Prehistory and Archaeology* of Middle America *see* MIDDLE AMERICA. (J. B. GN.)

V. EXPLORATION AND SETTLEMENT

The first Europeans to discover North America were probably Northmen, part of the population movement which carried Scandinavians to Normandy, England, Scotland, Ireland and the islands to the north and west between A.D. 700 and 1100. They were pirates, plunderers, traders and settlers attracted by fair lands and seas teeming with fish, or driven by population pressures or by the wrath of rivals or rulers at home.

About 1070 Adam of Bremen wrote of Norse discoveries in North America and references to the continent appear in the Icelandic annals of the next several centuries. But the "Saga of Eric the Red" and the "Saga of the Greenlanders" are the major sources. Apparently Bjarni Herjolfsson discovered North America in 985 or 986, when driven off course while sailing from Iceland to the Greenland settlements. In 1002 or 1003 Leif Ericsson (Eiriksson) sailed west from Greenland and gave the names Helluland, Markland and Vinland to sections of the American coast as he moved southerly along it. Leif wintered in Vinland and on his return, his brother Thorvald voyaged there, and was killed by natives. (See ERIC the Red.) About 1020 Thorfinn Karlsefni (*q.v.*) sailed to Vinland with three ships, taking domestic animals and women with him. His expedition spent three winters in the new land. After Karlsefni's return, Leif's half sister, Freydis, led an expedition to Vinland that was marred by vicious murders.

Locating the routes, landfalls and camps of the Vikings has stirred controversy because the evidence is fragmentary and contradictory. Also the Norse era apparently coincided with centuries of milder climate in northern latitudes, thus the vegetational clues in the sagas are misleading. Writers have suggested many locations for the Viking camps in northeastern North America. The authenticity of artifacts of alleged Viking origin, such as the Kensington stone found in Minnesota and the Beardmore weapons found in western Ontario, is questionable. In 1961, however, Helge Ingstad found a settlement site of Norse style at L'Anse au Meadow, Newfoundland. By the use of carbon-14 it was determined that the site was from the Viking era and a Norse spindle whorl indicated the presence of women.

The Vinland map, published in 1965, has been described as "the only surviving graphic record" of the Norse voyages to contain any element of experience." (R. A. Skelton *et al.*, *The Vinland Map and the Tartar Relation*, p. 239, Yale University Press, 1965.) It dates probably from 1431–49 and the writing that appears on the map supports Bjarni Herjolfsson's role, which has hitherto sometimes been questioned. It also suggests the presence in medieval Iceland of more evidence concerning Vinland than has survived and it strengthens the possibility that re-

FIG. 8.—"THE VINLAND MAP"

This map, drawn probably in the 1430s or 1440s by a monk in Basel, Switz., who presumably copied it from older maps that were subsequently lost, is the earliest known map showing part of North America and suggests that the Northmen discovered America in the 11th century. In the upper left-hand corner of the map is a reasonably accurate map of Greenland (labeled "Gronelada") and a curiously shaped island called "Vinlanda" (the Latin version of "Vinland," the name said to have been given to North America by Eric the Red's son Leif Ericson). The two large river mouths may represent Hudson Strait and the Gulf of St. Lawrence. The Latin inscription at upper left, translated into English, reads: "By God's will, after a long voyage from the island of Greenland to the south toward the most distant remaining parts of the western ocean sea, sailing southward amidst the ice, the companions Bjarni and Leif Eiriksson discovered a new land, extremely fertile and even having vines, the which island they named Vinland. Eirik [Henricus], legate of the Apostolic See and Bishop of Greenland and the neighboring regions, arrived in this truly vast and very rich land, in the name of Almighty God, in the last year of our most blessed father [Pope] Paschal [II], remained a long time in both summer and winter, and later returned northeastward toward Greenland and then proceeded [*i.e.*, home to Europe?] in most humble obedience to the will of his superiors"

evant information may have passed through English sailors to Bristol or even reached Spain and Portugal before North America was rediscovered.

Europeans entered an age of geographical discovery during the 15th century, reflecting developments in economic, social and political life under way for some centuries. Merchant groups had developed in western Europe, eager to expand trade and able to finance increasingly ambitious ventures. Most valuable of trade goods were the spices, coming overland from the orient to the eastern end of the Mediterranean. Since Italian merchants controlled the spice trade, merchants to the northwest wished to find new routes to the east.

The intellectual climate was prepared for an age of discovery by Renaissance scholars who developed an interest in the natural world, reviewed the speculations of the Greeks about the earth, and hazarded their own. At the same time Europeans were advancing in ship construction and improving navigational aids. After the first discoveries the new printing press allowed wide distribution of explorers' accounts. The rise of national states, Portugal, Spain, France, England and the united Netherlands, contributed also to the age of discovery. Monarchs encouraged exploring ventures in hope of increasing trade and acquiring treasure or territory. In the tradition of militant Christianity, Europeans wished to convert the non-Christians of the world. With the coming of the Reformation in the early 16th century, moreover, religious differences sharpened national rivalries as Protestants sought to outstrip the Roman Catholic Spanish and Portuguese, whose kings had divided the newly discovered areas of the world between themselves with papal approval in the treaty of Tordesillas (*q.v.*) of 1494.

1. Early Spanish Explorations.—In 1492 Christopher Columbus reached the Bahama Islands with three ships, proceeding then to Cuba and La Española (Hispaniola). A native of Genoa, Columbus sailed under a commission from the Spanish crown. Encouraged by tales of lands beyond the Canary Islands and stories of oriental riches, Columbus accepted the theory that the earth was spherical and sought the east by sailing west. He was probably motivated by a sense of Christian mission and a desire to rule new lands as Spanish governor, to win riches and to be known as a great geographer. Returning to Spain, Columbus maintained that he had reached the eastern fringe of Asia. Although he traversed much of the Caribbean and traced the mainland coast from Honduras to the Isthmus of Panama in three subsequent voyages, Columbus found no passage to Cathay, the medieval name for China. As governor of the Indies he also failed, but his discoveries of gold and pearls drew others and the royal fifth of such treasure interested the Spanish rulers. (*See* COLUMBUS, CHRISTOPHER.)

Based on La Española, Spanish captains probed the Caribbean, the Gulf of Mexico and Central America, hoping to find a western passage, to establish principalities and to exploit local resources. Shortly after 1500, Ferdinand V gave rights of conquest and gov-

ernment on the Mosquito Coast and the adjacent South American coastline to two adventurers, Diego de Nicuesa and Alonso de Ojeda. From their ventures, initially plagued by disease, dissension and hostile Indians, emerged Vasco Núñez de Balboa who led a force across the isthmus to the Gulf of Panama in 1513. (*See* BALBOA, VASCO NÚÑEZ DE.) From the isthmus, captains worked north along the Pacific and Caribbean shores.

By 1516 Diego Velázquez de Cuéllar had subjugated Cuba and he directed the attention of his lieutenants to the mainland. In 1519 Hernán Cortés (*q.v.*) led the third of such expeditions. Retracing the routes of his predecessors along the Gulf of Campeche, Cortés burned his boats at Veracruz and penetrated the mountains with a small force to Tenochtitlán (Mexico City), the Aztec capital of Montezuma II (*q.v.*).

By astute diplomacy, brilliant soldiering and adept handling of Indian allies Cortés broke and plundered the rich Aztec empire. Ignoring Velázquez in Cuba, Cortés became governor of the new region, established himself at Mexico City, and subdued the surrounding territories. During the mid-1520s his men clashed in Honduras with forces from the isthmus. The general outlines and topography of Central America and southern Mexico were now becoming clear.

Some Spanish adventurers pushed north from La Española. In 1513 Juan Ponce de León threaded the Bahamas and skirted peninsular Florida. (*See* PONCE DE LEÓN, JUAN.) Alonso de Pineda (1519) traced the shore of the Gulf of Mexico from the Florida keys to the Pánuco river in Mexico. During 1524–25 the Portuguese Esteban Gomes coasted from the Grand Banks to Florida in Spanish service. Later expeditions probed the continental interior. Pánfilo de Narváez (*q.v.*) landed a large party in Florida in 1528. Eight years later, four survivors, two of whom were Alvar Núñez Cabeza de Vaca and the Negro slave Esteban, reached northern Mexico after walking from Galveston bay. Cabeza de Vaca's tale encouraged minds inflamed by stories of rich Inca treasure and Indian legends of the seven golden cities of Cibola.

Expeditions begun by Hernando (Fernando) De Soto and Marcos de Niza (Fray Marcos) in 1539 and by Francisco Vázquez de Coronado in 1540 followed routes which stretched, when combined, from the Grand canyon to the Savannah river, ascended the Mississippi valley beyond the Ohio and linked the upper waters of the Brazos to the Kansas river. (*See* DE SOTO, HERNANDO; NIZA, MARCOS DE; CORONADO, FRANCISCO VÁSQUEZ DE.) Early major Spanish explorations were completed in 1542–43 when Juan Rodriguez Cabrillo and Bartolomé Ferrelo surveyed the Pacific coast from lower California to a point beyond latitude 42° N., although minor figures explored in the eastern Appalachians and the southwest after 1550. (*See* also LATIN AMERICA.)

2. French, English and Dutch Explorations Before 1772.—While the Spanish exploited the lower latitudes, other European captains ranged the northern coasts. Such was the voyage of the Genoese John Cabot (*q.v.*) in 1497, backed by the British crown and Bristol merchants, and believed to be the second Bristol expedition to reach North America after 1480. Subsequent English, Portuguese and French expeditions found little of interest until the Frenchman, Jacques Cartier (*q.v.*), ascended the St. Lawrence river in a series of expeditions beginning in 1534. But he found no treasure, and interest in the interior waned. In 1578–79 Sir Francis Drake (*q.v.*) explored the Pacific coast of North America to 48° seeking a passage to the east. Increasingly, however, Frenchmen and Basques fished the Gulf of St. Lawrence and incidentally began a trade in furs with the natives. American furs, particularly beaver, were sufficiently popular in Europe by 1600 that the French king tried to nurture the trade by assigning it as a monopoly to favoured merchants.

French fur traders founded Port Royal in 1605 but in 1608 Quebec became the centre of the trade. From there the governor of French Canada, Samuel de Champlain, hoped also to discover a Pacific passage (*see* CHAMPLAIN, SAMUEL DE). The fur trade also drew the French into the interior since it was always profitable to forestall tribes seeking to act as middlemen. After 1615 the desire of the Recollet (Franciscan), Jesuit and Sulpician religious orders to Christianize the Indians contributed to exploration. But the hostile Five Nations of the Iroquois (*q.v.*), west of the Hudson and below the St. Lawrence and Lake Ontario, impeded the French. Allies of the Dutch at Fort Orange, these Iroquoians fought the northern tribes friendly with the French. Because of the Iroquois the French initially avoided the lower lakes and followed the Ottawa into the interior, traversing to Georgian bay. From the explorations of Champlain, of subordinates like Étienne Brulé, and of the missionaries, the French, in 1650, understood the St. Lawrence-Great Lakes system in a general way, although western Lake Superior and southern Lake Michigan were unexplored. They knew also of both the Hudson and Susquehanna river routes to the sea and had heard of a northern sea beyond the Laurentian divide.

During the 1660s, French activities impinged on those of the English. Annoyed by trading restrictions in New France and by the hampering Iroquois, Pierre Esprit, sieur de Radisson, and Médart Chouart, sieur de Groseilliers, sought British backing to establish a northern trade outlet, having perhaps been themselves to James bay. As a result Englishmen organized the Hudson's Bay company (*q.v.*). They were already familiar with the approaches to Hudson bay and its general character through the efforts of English explorers including Sir Martin Frobisher, John Davis and Henry Hudson (*qq.v.*), who had all sought a northwest passage to the orient around 1600.

The French now attempted to widen their sovereignty in North America. During 1671–72, Paul Denis, sieur de St. Simon, followed the Saguenay and Rupert rivers to James bay. Simon François Daumont, sieur de St. Lusson, proclaimed French rule of interior North America at Sault Ste. Marie in 1671. Daniel

FIG. 9.—PRINCIPAL EXPLORERS OF NORTH AMERICA: GENERAL LOCATION AND DATES OF THEIR MOST IMPORTANT DISCOVERIES

Greysolon, sieur Dulhut (Duluth), declared French sovereignty at Lake Mille Lacs (in present Minnesota) and descended the St. Croix and Mississippi rivers to the Wisconsin while rescuing Father Louis Hennepin from the Sioux Indians. The French also tried to push south to Spanish territory in order to confine the British settlements along the Atlantic coast. In 1673 Louis Jolliet and the Jesuit, Jacques Marquette (*qq.v.*), followed the Fox-Wisconsin traverse from Green bay and descended the Mississippi almost to the Arkansas, returning by the Illinois river to Lake Michigan. Nine years later René Robert Cavelier, sieur de La Salle, descended to the mouth of the Mississippi and claimed the whole region, which he named Louisiana, for France. (*See* La Salle, René Robert Cavelier, Sieur de.)

After reaching the lower Mississippi valley, the French sought trade connections with the Spanish settlements. Notable in this effort were the expeditions of Louis Juchereau de Saint Denis from Natchitoches, La., to San Juan Bautista (Villahermosa), Mex., in 1714; of Bernard de la Harpe along the Red, Arkansas and Canadian rivers between 1719 and 1722; and of Pierre and Paul Mallet. Beginning in the winter of 1738–39 the Mallet brothers followed the Missouri, the Platte and the South Platte into the high plains, angled southwest to Taos and Santa Fe and returned to the Mississippi along the Canadian and Arkansas rivers. In the northern plains Pierre Gaultier de Varennes, sieur de la Vérendrye, countered British competition by pushing trading posts beyond Lake Superior, baiting his request for a western trading monopoly by promising to seek the Western sea. Between 1731 and 1744, Vérendrye and his sons discovered and described lakes Winnipeg, Winnipegosis and Manitoba and their relation to the major rivers of the region. They reached the Black hills and mapped the upper Missouri but decided that the Saskatchewan river provided the best route to the Pacific.

While the French ranged from James bay to the Gulf of Mexico, the British and Dutch explored below the Great Lakes and east of the Mississippi. Englishmen established Jamestown in 1607 and the Dutch occupied the Hudson valley following its discovery by Henry Hudson in 1609. By 1650 fur traders were searching for passes through the Appalachian barrier. During 1671 Virginians discovered the upper Kanawha. Two years later James Needham reached a Cherokee village on the upper Tennessee river and accompanied braves to the Kanawha and the Ohio rivers and to the junction of the Chattahoochee and the Flint rivers. During 1692–94 Arnout Cornelius Viele from Albany descended the Ohio, perhaps to the Mississippi. During the late 1690s, Carolinians reached the junction of the Arkansas and Mississippi rivers and followed an expatriate French trader, Jean Couture, down the Tennessee to the Ohio. Carolinian competition with French and Spanish in the Gulf hinterland revealed the topography of this region.

Initially the Hudson's Bay company showed little interest in the interior, allowing superior trade goods to draw the Indians to Hudson bay. Henry Kelsey's expedition during 1690–92 was an exception to this policy. Kelsey ascended the Hayes river from York Factory, crossed the head of Lake Winnipeg and explored beyond Lake Winnipegosis. Spurred by French activity, the company sent Anthony Henday into the interior in 1754. He pushed beyond longitude 113° W. between the major branches of the Saskatchewan. Seeking in 1770–72 to locate the source of copper brought by Indians to company posts, Samuel Hearne reached the lower Coppermine river, crossing Great Slave lake to take the Slave river while returning. Hearne's discoveries long discouraged exploration in the barren lands northeast of his route.

3. Pacific Coast, Northwest and Arctic Explorations.—Russian interest in the relation of Asia to North America prompted exploration in the early 18th century. Vitus Jonassen Bering (*q.v.*), although his achievement was disparaged, traversed Bering strait in 1728. Both he and Alexei Chirikov reached southern Alaska in 1741 and Russian traders began the China trade in Aleutian sea otter and seal. Russian efforts provoked response from Spain, Great Britain, France and ultimately the United States.

By sea, Spanish expeditions of 1774 and 1775 coasted from California to latitude 57° N. Capt. James Cook (*q.v.*), cruised from Oregon to Bering strait in 1778, seeking the terminus of a northwest passage. After his death the expedition reached latitude 70° 44″. Official Russian, Spanish, British and French expeditions and numerous traders probed the northwestern coast after 1785. On land, the Spanish pushed their settlements to San Francisco bay during the 1760s and 1770s, exploring back from the coast in the process and seeking trails to link this frontier to Santa Fe and Taos. During 1776–77 Father Silvestre Vélez de Escalante led a notable expedition from Sante Fe northwest to Utah lake, southwest to Sevier lake and the upper Virgin river, and back to Santa Fe.

On the northern plains, the North West company of Montreal replaced the French fur traders after New France passed to Great Britain in 1763. Seeking to forestall the Hudson's Bay company, and to tap the fur fields of the Russians, Alexander (later Sir Alexander) Mackenzie (*q.v.*) descended the Mackenzie river from Great Slave lake to the Arctic ocean in 1789. In 1793 he followed the Peace river into the Rockies, traversed to the Fraser and then cut overland to the Pacific.

After the United States purchased Louisiana, the official Lewis and Clark expedition (*q.v.*) ascended the Missouri, crossed from the Jefferson fork to the Pacific slope and reached the mouth of the Columbia in 1805. Traders and trappers soon explored the American Rockies and Great Basin. To the north, British traders explored the Fraser and upper Columbia and entered the upper Yukon country. Meanwhile, representatives of the Russian-American company probed interior Alaska. After 1850 exploration in the American and British western possessions became increasingly scientific, culminating in the establishment of official geological surveys.

Prior to 1818 explorers by sea in the north had stopped short of Point Barrow and on land had reached the arctic coast only at the Mackenzie and the Coppermine rivers. In the next 40 years, the British admiralty, the Hudson's Bay company and private scientific ventures changed the situation. The land-based expeditions of Sir John Franklin, John Rae (*qq.v.*) and Thomas Simpson explored much coastline between Point Barrow and the Melville peninsula. On sea, Frederick W. Beechey filled the gap west of Point Barrow, Lt. William (later Sir William) Edward Parry (*q.v.*) sailed from Baffin bay to Melville Island and Sir John Ross (*q.v.*) explored the Boothia peninsula and, with his nephew James (later Sir James) Clark Ross (*q.v.*), located the north magnetic pole. When Sir John Franklin sought the northwest passage in 1845, ice trapped his ships south of Prince of Wales Island and the crews perished. During the next decade searching parties amassed information about the arctic. But not until 1903–06 did Roald Amundsen (*q.v.*) sail from the Atlantic to the Pacific north of the continent and only in 1915–16 did Vilhjalmur Stefansson discover the last major islands at the north of the Canadian archipelago.

4. European Settlement.—Although Swedish and Dutch traders established colonies on the Delaware and the Hudson during the 17th century and Russian traders were active on the west coast of North America for more than a century, their contributions in settling North America were minor in comparison to those of the Spanish, French and English.

Spanish Settlement.—During the 16th century individuals, willing to organize expeditions and transport colonists, obtained contracts from the Spanish crown, allowing them to exploit regions in North America. Although the contracts conveyed extensive rights of government and economic privileges, the authority of these impresarios was usually soon challenged by royal officials. After 1535 the viceroyalty of New Spain provided the major frame of government for Spanish holdings in the Caribbean and on the mainland, north of the Isthmus of Panama.

Dissatisfaction with prospects at home, and desire to find adventure and wealth, or to carry Christianity and European culture abroad, brought Spaniards to the new world. Impresarios, and sometimes the crown, encouraged such movement, although only Spanish citizens of undoubted orthodoxy could migrate. By 1570 the white population of New Spain numbered about 54,000, mainly

of Andalusian antecedents. The possibility of riches, the sophistication of many natives and the climate, encouraged the Spanish to use Indian labour widely. The crown soon forbade Indian slavery but it persisted, and other systems of forced labour also evolved. Spanish arms, European diseases and the new regimen almost extinguished the island natives, whom the Spanish replaced by African slaves. There were more than 93,500 Negroes and mestizos in New Spain by 1570. Although the mainland Indians also decreased in numbers they always dominated the population, numbering about 3,000,000 in 1570. Spanish settlement was characterized by considerable miscegenation.

The success of Cortés caused an exodus from the Caribbean islands. The Greater Antilles developed a prosperous sugar plantation economy, but smaller islands remained unoccupied. After the initial conquests, Spanish settlement on the mainland reflected mining and agricultural opportunities and strategic considerations. The preliminary conquest was complete in Central America by 1600 but portions of the region remained unconquered in 1700. By 1600 Spanish colonization, pushing north from the valley of Mexico, had reached points due west of the mouth of the Rio Grande. Although silver and gold mines like those of Zacatecas produced concentrations of population, much grain and livestock was produced in New Spain. Dominican, Franciscan and Jesuit missions helped pacify the Indians in frontier regions. At times, colonies of civilized Indians were moved to the frontier to assist soldier and missionary.

After Huguenot colonization on the Florida coast threatened Spanish shipping in the Bahama channel, the Spanish finally occupied Florida during the 1560s. Missionary efforts in Virginia failed but missions along the Carolina and Georgia coasts survived. At the end of the 16th century Juan de Oñate colonized New Mexico and Santa Fe was established in 1610. During the 18th century the Spanish pushed their Pacific frontier from the Sonora region to San Francisco bay.

Settlement of the British Colonies and the United States.—After the Virginia company of London founded Jamestown, the English established numerous colonies along the North American coast from Maine to Georgia and in the West Indies. Individuals and groups sought patents from the British crown conferring territorial and administrative privileges in the new world upon them. Economic opportunities attracted most colonial promoters, although experience in Virginia dispelled hope of matching Aztec treasure. But desire to modify Anglican church doctrines, or to alleviate the condition of nonconformists and indigents influenced promoters in a number of colonies. The crown never closed the colonies to religious dissenters. Although companies or proprietors originally controlled the colonies, they were ultimately in most cases brought directly under the crown.

The English colonists engaged in farming, fishing, shipbuilding and trade, with tobacco, rice and indigo important in the southern mainland colonies and sugar plantations characterizing the Indies. Although important, the mainland fur trade was never dominant. Mortality was high initially in Virginia and Plymouth but emigration attracted Englishmen because of enclosures on estates in Britain, high land prices, dissatisfaction with Stuart political and religious policies and the generous colonial systems of land disposal and government. Many emigrated as indentured servants. During the 1630s a large Puritan migration arrived in Massachusetts, soon itself supplying emigrants for Connecticut, Rhode Island and New Hampshire. A British Quaker migration began to develop Pennsylvania in 1682. Germans and Scotch-Irish came after 1700 to settle mainly in Pennsylvania and the colonies to the south. Scottish, Welsh and Huguenot settlers arrived also. After 1600 many African slaves were brought to the southern colonies. By 1760 the colonies in North America were supporting about 2,000,000 inhabitants of European and African origin.

Indian relations, land policy, topography, soil fertility and a number of minor factors modified settlement. The agricultural frontier was in the piedmont region until 1700 and was roughly marked by the Alleghenies until 1800. The Mississippi provided the frontier of the early 19th century in the United States. During the 1840s pioneers established the Oregon, Utah and California settlements. Subsequently miners flocked to the cordilleras as a succession of gold and silver strikes followed the California discoveries of 1848. Between 1860 and 1900 farmers occupied the high plains. Established settlements provided settlers for new lands, the pioneers migrating generally along isothermal lines. Immigration to the United States averaged about 10,000 annually between 1790 and 1830; by the 1850s the average inflow had risen to slightly more than 280,000 people yearly and during the 1890s it was almost 370,000. Many immigrants remained in the older regions, but Germans, Scandinavians and British particularly helped to settle the northern territories and states. The small farms and urban orientation of these regions apparently attracted the foreign-born more strongly than did the systems of slavery and plantation agriculture prevalent in the southern section of the United States before the Civil War. (*See also* AMERICAN FRONTIER.)

FIG. 10.—AREAS CLAIMED BY BRITAIN, FRANCE AND SPAIN IN NORTH AMERICA IN 1750

Settlement of the French Colonies and Canada.—French settlements developed in New France (Canada) and Acadia (the coast of Nova Scotia) on the North American mainland. The fur traders, required to transport colonists under their trading monopolies, performed these obligations unsatisfactorily. There were only 1,800 French on the Bay of Fundy when Acadia passed to England in 1713. Ineffective administration by the merchant company holding the fur monopoly in New France led the crown to assume direct control in 1663 when the colony numbered about 2,500. Thereafter settlers were obtained by offering free passage and land on easy terms and by inducing French soldiers to remain in New France. The government conveyed girls from France as wives for settlers and seigneurs brought in colonists to work their land grants. For a time during the 18th century French criminals were transported to the colony. After 1680 the

population grew mainly from natural increase. Since royal policy barred dissenters and French agriculture experienced few disruptive changes, little interest in emigration developed in France. Settlement in New France spread out from Quebec, Trois Rivières and Montreal along the St. Lawrence, penetrating the back country along the Richelieu but little elsewhere. Although primarily a farming settlement by the 18th century, New France produced little surplus and the fur trade dominated its commerce.

Established in 1699, Louisiana (*q.v.*) developed under a merchant proprietor and later the Compagnie des Indes Occidentales. In 1731 it became a royal province and was enlarged to include the Illinois country. The fur trade, agriculture and lead mining in Missouri occupied the residents.

By 1760 the French mainland colonies of North America had a European population of about 80,000 while the Indies numbered an additional 45,000 plus about 300,000 slaves. Aside from the French nucleus, Great Britain, then including Ireland, and the American colonies provided most of the settlers for the British provinces which ultimately amalgamated as the dominion of Canada. During the 1760s New Englanders moved to Nova Scotia and merchants from New York and New England established communities in Quebec and Montreal. The American Revolution caused Loyalists to migrate to Upper Canada, Nova Scotia and New Brunswick. Between 1790 and 1815 many settlers from the United States entered Upper and Lower Canada. After 1815 immigration from the British Isles became important, including Irish famine refugees and Scottish crofters (tenant farmers). The Fraser river gold rush in 1856 drew a polyglot population to British Columbia but this province developed slowly. Although Lord Selkirk established a colony of Scottish settlers in the valley of the Red River of the North in 1812 (*see* RED RIVER SETTLEMENT), and the fur trade left some retired servants and métis, or half-breeds, few settlers entered the Canadian prairies before 1890. The government actively promoted the region and by 1930 settlers from the older provinces, from the United States, Great Britain, western and central Europe had occupied most of the arable land.

Major Territorial Adjustments in North America.—The European monarchs assumed that their sovereignty followed their nationals in the new world but colonial policies, European wars and American rivalries produced territorial adjustments in North America. When the Spanish concentrated on the mainland, English, French, Dutch and Danes seized unoccupied Caribbean islands, from the Bahamas to the Windward group during the 17th century. In 1655 the British occupied Spanish-held Jamaica and subsequently gained footholds on the Honduras and Mosquito coasts. The French gained the uninhabited portions of Haiti.

During 1664 England seized New Netherland and in 1713 acquired French claims to Acadia, Newfoundland and Rupert's Land, the region draining into Hudson bay. In 1763 France ceded all mainland territory east of the Mississippi to Great Britain and west of that river to Spain. Concurrently Spain surrendered Florida to the British. Following the American Revolution, the United States in 1783 obtained the territory south of Canada, and east of the Mississippi, while Spain regained Florida.

Napoleon wrested Louisiana from Spain in 1800 but revolt in Haiti jeopardized French plans in America and paved the way for the independence ultimately of Haiti and the Dominican Republic. The United States purchased Louisiana from France in 1803 (*see* LOUISIANA PURCHASE). The Spanish transferred Florida to the United States in the treaty of 1819, the United States accepting here also a western boundary for Louisiana which left Texas in Spanish hands.

Beginning in 1810 revolution shattered the Spanish empire in America. On the mainland Mexico, Guatemala, El Salvador, Honduras, Nicaragua and Costa Rica emerged, although the countries of Central America together formed the Central American Union between 1823 and 1839 (*see* CENTRAL AMERICA).

In 1835 settlers from the United States in Texas revolted, proclaiming a republic which gained admission to the United States in 1845. After a short war with the United States, Mexico in 1848 renounced claims to Texas and also ceded New Mexico and upper California. In 1853 the United States acquired the Gadsden Purchase lying south of the Gila river (*see* GADSDEN PURCHASE).

The boundary between the United States and the northern British provinces was extended along the forty-ninth parallel beyond Lake of the Woods to the crest of the Rockies in 1818 and to the Pacific in 1846. Meanwhile the disputed Maine-New Brunswick boundary was fixed in 1842. Russia and Great Britain set the interior boundary of Alaska by treaty in 1825 and Russia sold this region to the United States in 1867.

Important changes in territorial administration occurred in the British provinces after 1860. In 1867 Nova Scotia and New Brunswick joined Canada (modern Ontario and Quebec), in the dominion of Canada. Canada purchased Rupert's Land from the Hudson's Bay company in 1869, British Columbia joined the federation in 1871, Prince Edward Island in 1873 and Newfoundland, including Labrador, in 1949.

Following the Spanish-American War in 1898, Cuba gained independence from Spain, and Puerto Rico was ceded to the United States (as were Guam and the Philippines). Panama declared its independence from Colombia in 1903 and granted a Canal Zone in perpetuity to the United States. The United States purchased the Virgin Islands from Denmark in 1917, and in 1958 the West Indies federation was established within the Commonwealth of Nations. The federation broke up in 1962. *See* also AMERICAS, THE; LATIN AMERICA; CENTRAL AMERICA; and ARCTIC, THE; and the *History* sections of UNITED STATES (OF AMERICA); CANADA; MEXICO; GREENLAND; WEST INDIES; and of articles on the Central American and Caribbean republics. (A. G. Bo.)

VI. POPULATION

North America, with approximately 9% of the world's population, ranks as the third most populous continent in the world. Because it occupies about 16% of the world's land area, its population density is below that for the world as a whole.

1. Distribution.—People are quite unevenly distributed within the continent. The southeastern quarter of Canada and the eastern United States contains one of the world's great population concentrations. In this area live more than four-fifths of the U.S. population and nearly two-thirds of Canada's, comprising the densest urban concentrations and many of the largest cities of the two countries. The most densely settled area for its size is to be found about the mouth of the Hudson river in what is known as the New York-Northeastern New Jersey Standard Consolidated area or Greater New York. From this centre northeastward to Boston and southwestward to Baltimore is the largest aggregation of people on the whole continent.

Some of the islands of the West Indies are also very densely populated. Barbados contains an average of 1,400 persons per square mile. Since a majority of the population of this tiny island of the West Indian group is rural, its density is comparable to that of some of the more heavily populated rural areas elsewhere in the world. Other Caribbean islands which have high rural densities include Martinique, Puerto Rico, Jamaica, the Windward Islands, the Leeward Islands and the republic of Haiti.

The distribution of population within Mexico is representative of many other Middle and South American republics. Almost one-half of Mexico's inhabitants are found in the basins and valleys clustering about the capital city, in a district representing less than one-seventh of the country's entire area.

Two large, sparsely populated areas characterize the continent of North America. One of these is in Canada, which is a relatively unoccupied country except for a rather narrow fringe scarcely more than 100 mi. wide along a part of the northern border of the United States. The second area is the western half of the United States with the exception of portions of Washington and Oregon west of the Cascade ridge, central and southern California, and the irrigated lands along the major river valleys. Alaska is the United States' largest but least densely populated state.

2. Population Growth.—In the second half of the 20th century most political divisions in North America were experiencing

a rapid growth in population, exceeding the average annual rate of 1.8% for the world as a whole. Canada's annual growth was about 3.0%; that of the United States 1.6%. The growth of these two countries is due principally to increases in their birth rates following World War II, their extremely low death rates and to an excess of immigration over emigration.

The islands of the Caribbean and the republics of Middle America are also growing at annual rates far in excess of those of many other parts of the world. Among them are Costa Rica, 4.9%; Dominican Republic, 3.6%; and Nicaragua and Honduras, both with a percentage growth of about 3.4% annually. The growth throughout Middle America is the result of extremely high birth rates and declining death rates. They have an average crude birth rate of about 37 per 1,000 population as compared with a world average of 36. Death rates for the area as a whole average 10 per 1,000 population, compared with 18 for the world.

North America has been an area of considerable population growth for most of its recorded history. From about 1880 to mid-20th century the population of the continent increased almost threefold. In 1850 the United States had a population of 23,300,000, whereas that of Canada was 2,400,000. In 1960 the population of these countries had grown to a total of 196,900,000, or a total increment of 666%.

3. Racial Composition.—In Canada, about 44% of the total population are of British stock, 30% are French, and about 10% have been classified as having mostly German, Scandinavian and Ukrainian backgrounds. The native groups comprise Indians and Eskimos, but these make up only slightly more than 1% of the total population.

Of the total U.S. population in 1960, 88.6% were white, Negroes constituted 10.5% and the remaining fraction consisted of Orientals and others.

The population of Middle America includes Indians, descendants of Europeans, Negroes and mixed peoples. Indians constitute more than 50% of the population of most of the mainland republics, but great variations exist among countries. Costa Rica, for example, is almost entirely white; Guatemala is predominantly Indian; Mexico classifies about 30% as pure Indian, 15% white and 55% mestizo. The predominant stock of many of the West Indian islands is Negro. Jamaica has a population which is about 78% Negro and 14% mulatto. The population of Haiti is 90% Negro with the remainder being mulatto of French-Negro descent. Only a very small proportion of the population of Middle America is of purely white descent.

On the continent as a whole, more and more people are moving to urban centres. The 1960 census showed the United States as being 69.9% urban. In 1961 Canada had an urban population of 69.6%.

NORTHAMPTON, EARLS AND MARQUESSES OF. The earldom of Northampton was united with that of Huntingdon until 1136, again possibly from about 1146 to 1157 and for the last time between 1174 and 1184. Both titles were first bestowed in 1065 upon WALTHEOF (d. 1076), son of Siward, earl of Northumberland. Waltheof, himself earl of Northumberland from 1072, was involved in a conspiracy against William I in 1075, forfeited his titles and was executed on May 31, 1076. His daughter Matilda (d. 1130/31) married first SIMON DE ST. LIZ (d. *c.* 1111), who was styled earl of Northampton by 1091, and secondly DAVID I (*c.* 1082–1153), king of Scotland. David held the titles from 1113–14 until 1136. His stepson, the second SIMON DE ST. LIZ (d. 1153), was recognized as earl of Northampton, possibly by 1141, and may later in Stephen's reign also have held the Huntingdon title. His son, another SIMON (*c.* 1138–1184), was probably recognized as earl of Northampton from 1155 to 1157; he held both titles after 1174. On his death in 1184 without issue, the earldom of Huntingdon passed to David, a grandson of King David I; the title of earl of Northampton became extinct.

WILLIAM DE BOHUN (*c.* 1312–1360), youngest son of Humphrey de Bohun, earl of Hereford and Essex, was created earl of Northampton in March 1337. With his elder brother Humphrey, he helped the young Edward III rid himself of Roger Mortimer's tutelage in 1330. He served in the Scottish and French wars of Edward III and was at the battle of Crécy (1346) and the siege of Calais. He was succeeded at his death in Sept. 1360 by his son, HUMPHREY DE BOHUN (1342–1373), who also inherited the earldom of Hereford and Essex in 1361. Humphrey died in Jan. 1373, leaving only two daughters. The elder, Eleanor, married Thomas of Woodstock (d. 1397), afterward duke of Gloucester, the youngest son of Edward III; but although he received the 3rd penny of the county in 1374, he seems never to have been recognized as earl of Northampton. The 3rd penny of the county was transferred in Dec. 1384 to HENRY BOLINGBROKE (1366–1413), earl of Derby, afterward king Henry IV, the husband of Humphrey's younger daughter Mary. On his accession as king in Sept. 1399, all his honours became merged in the crown.

WILLIAM PARR (1513–1571), only son of Sir Thomas Parr and brother of Catherine, 6th wife of King Henry VIII, was created marquess of Northampton on Feb. 16, 1547, shortly after the accession of Edward VI. Widely influential, he was created lord great chamberlain for life in 1550. He was a leader of the Protestant party and was one of those who did homage to Lady Jane Grey after Edward VI's death. Attainted under Queen Mary in Aug. 1553, his title was restored by Elizabeth I. He died without issue on Oct. 28, 1571, and his title became extinct.

HENRY HOWARD (1540–1614), younger son of Henry Howard (d. 1547) earl of Surrey, was created earl of Northampton on March 13, 1604. Although restored in blood in 1559 (his father had been attainted and executed in Jan. 1547) he won little favour in Elizabeth's reign and was arrested in 1571 on a charge of aspiring to marry Mary Stuart. He died unmarried in London on June 16, 1614, and his title became extinct.

WILLIAM COMPTON (*c.* 1568–1630), 2nd Lord Compton, was created earl of Northampton on Aug. 2, 1618. His wife was Elizabeth, daughter of Sir John Spencer, lord mayor of London from 1594 to 1595. Compton died in London on June 24, 1630. His son SPENCER COMPTON (1601–1643) accompanied Prince Charles (afterward Charles I) to Spain in 1623 and in the Civil War was colonel general of royal forces in Northamptonshire and Warwickshire. He was killed commanding the victorious royalist forces at the battle of Hopton Heath on March 19, 1643. William's son JAMES (1622–1681), also a royalist, held household appointments under Charles II. James's 3rd son, Spencer Compton, earl of Wilmington was prime minister (first lord of the treasury) from Feb. 1741 until Aug. 1743.

On the death of JAMES COMPTON (1687–1754) on Oct. 3, 1754, without male issue, the barony of Compton descended through his daughter Charlotte, while the earldom of Northampton passed to James's brother GEORGE (1692–1758). George was succeeded in turn by his nephews CHARLES COMPTON (1737–1763) and SPENCER COMPTON (1738–1796). Spencer's son CHARLES (1760–1828) was created marquess of Northampton on Sept. 7, 1812. WILLIAM BINGHAM COMPTON (1885–) is 6th marquess and 14th earl of the Compton line.

NORTHAMPTON, a municipal, county and parliamentary borough and the county town of Northamptonshire, Eng., lies 66 mi. N.W. of London by road. Pop. (1961) 105,421.

The streets of the business centre of Northampton converge on All Saints' church which was rebuilt during the late 17th century in the classical style. Other noteworthy churches are St. Sepulchre's, which retains a rotunda (*c.* 1110); St. Peter's, a magnificent example of late Norman architecture; and St. Matthew's, masterpiece of the late 19th-century local architect Matthew Holding and now containing a "Madonna and Child" by Henry Moore and a painting of the crucifixion by Graham Sutherland. The nave of the Roman Catholic cathedral (bishopric founded 1850) was built in 1864; a new chancel and a central tower were completed in 1960. At nearby Hardingstone is one of the three surviving Eleanor crosses. The guildhall (1864 with later additions) is a sumptuous example of Victorian Gothic designed by Edward Godwin. The borough has a theatre, two museums and an art gallery, grammar schools, a school of art and a college of technology.

Northampton lies in the valley of the river Nene, and thus is bypassed by the Grand Junction canal, and the London Midland region main railway line. A branch canal was completed in 1815, and a branch railway in 1845; the present Castle station, on the site of the medieval castle, was opened in 1881 when a loop line via Northampton was constructed to relieve congestion on the main line. The London–Yorkshire motorway, opened in 1959, passes near the borough boundary (southern access at Collingtree, northern at Heyford, respectively 3 and 5 mi. from the town centre). A small private airfield exists at Sywell, 6 mi. N.E.

The principal industry in Northampton is shoe manufacturing, traditionally shoes for men, but since the end of World War II there has been considerable production of women's shoes as well. The number of shoe factories and of workers has fallen but output has remained steady. Leather is also produced in large quantities. Engineering is well established in Northampton and some of the surrounding villages; manufactures include tapered roller bearings, motor-vehicle components, earthmoving equipment, lifts (elevators) and electronic instruments. The town is an important retail centre, serving Northamptonshire and north Buckinghamshire.

The earliest reference to Northampton occurs in a chronicle under the year A.D. 914. Town walls and a castle were built by Simon de Senlis (*c.* 1100). Northampton was a place of importance during the early middle ages, and its first charter was granted in 1189, but about 1300 it began to decline. Several national councils, some of the early parliaments and the trial and condemnation of Thomas Becket (1164) were held in the castle. The Yorkists defeated the Lancastrians (1460) just outside the town

walls during the Wars of the Roses. Northampton was for parliament during the Civil War, and after the Restoration the castle and town walls were demolished. Much of the town was destroyed by fire in 1675. Shoe manufacturing began in the 17th century, but the industry on a large scale did not develop until after 1815.

During the late 19th century the inhabitants of Northampton acquired a national reputation for the expression of uncompromising radical opinions. Charles Bradlaugh, the social reformer, was elected member of parliament in 1880; parliament, however, refused to acknowledge him until 1886, although he had been re-elected by his constituents on four subsequent occasions. In 1923 Margaret Grace Bondfield, the first woman member of the cabinet, was elected member of parliament for the borough.

At Great Brington, 6 mi. N.W. of Northampton, the church contains the tombstones of the brothers Laurence and Robert Washington, the former (d. 1616) an ancestor of President George Washington. Both stones display the Washington arms. The family moved from Sulgrave, also in Northamptonshire, to Brington about 1600: according to borough records an earlier Laurence Washington, grandfather of Laurence and Robert, was mayor of Northampton in 1532 and 1545. (V. A. H.)

NORTHAMPTON, a city of west central Massachusetts, U.S., on the Connecticut river, is located about 16 mi. N. of Springfield; the seat of Hampshire county.

Since its founding in 1654, chiefly by settlers from Connecticut, Northampton's character has reflected much of the general development of New England. Throughout the 18th century it was a self-sufficient agricultural community; its pastor from 1729 to 1750 was Jonathan Edwards (*q.v.*). After the American Revolution it was the scene of several debtors' demonstrations during Shays's rebellion. (*See* MASSACHUSETTS: *History.*)

In the 19th century Northampton became a major stagecoach stop and the northern terminus of a canal from New Haven, Conn., completed in 1834. Railroad connections with the south and east came in 1845. The establishment of a woolen factory in 1809 ushered in a slow transition from agriculture to industry, which boomed after the American Civil War. Manufactures include brushes, cutlery, wire cable, caskets and optical equipment. The silk industry, once the leader, declined in the 1920s.

Smith college was founded under the will of Sophia Smith (1796–1870) of nearby Hatfield to provide young women with a college education equal to the best offered to men. Chartered in 1871 and opened at Northampton in 1875, Smith became the largest independent college for women in the U.S. The Smith college school for social work, which trains social caseworkers and prepares students for the degree of master of social sciences, was founded in 1918. From 1925 the college sent groups of students abroad to study during their junior year.

George Bancroft, the historian, founded his Round Hill school for boys in 1823 on the site occupied after 1867 by the Clarke School for the Deaf. The People's institute, now primarily a community centre, was founded by the novelist George Washington Cable in 1896 for adult education.

Northampton was also the home of Sylvester Graham (1794–1851), the advocate of coarse flour for whom the graham cracker was named. Calvin Coolidge, 30th president of the U.S., who began his law practice in Northampton, died there in 1933.

Incorporated as a town in 1656 and as a city in 1883, Northampton is part of the Springfield-Holyoke standard metropolitan statistical area. For comparative population figures *see* table in MASSACHUSETTS: *Population.* (D. H. S.)

NORTHAMPTON, ASSIZE OF, a number of ordinances agreed upon by the king of England and the magnates in council at Northampton in 1176. They were issued as instructions to six committees of three judges each, who were to visit the six circuits into which England was divided for the purpose. Parts of the assize repeated the substance of some provisions of the Assize of Clarendon (1166), but with several differences. Thus, arson and forgery now appeared among the crimes about which juries of presentment were to inquire, and those who failed at the ordeal were to lose a hand as well as a foot. An important section defined some of the rights of the heir, the lord (or lords) and the widow of a deceased free tenant; its protection of the heir's right to succeed to land established the possessory action of *mort d'ancestor.* The justices were also ordered to hear pleas of novel disseizin (recent ejectment from a free tenement) arising since May 1175 and to try proprietary actions commenced by the king's writ for the recovery of land held by the service of half a knight's fee or less. In their fiscal capacity they were to inquire into escheats, churches, lands and women in the king's gift. Monies accruing to the king from proceedings before the justices were among the receipts for which royal bailiffs were to account at the exchequer. As a result of the rebellion of 1173–74 it was provided that an oath of fealty should be taken by all; "to wit, barons, knights, freeholders, and even villeins (*rustici*)," and that anyone who refused should be arrested as the king's enemy; the justices were to see that castles whose demolition had been ordered were razed, to inquire into castle-guard and to prepare a register of fugitives.

See A. L. Poole, *From Domesday Book to Magna Carta* (1951). The text is printed in W. Stubbs, *Select Charters*, 9th ed. (1913), an English translation in *English Historical Documents*, vol. ii, ed. by D. C. Douglas and G. W. Greenaway (1953). (ER. S.)

NORTHAMPTONSHIRE (abbr. NORTHANTS), an east midland county of England, is bounded northwest by Rutland and Leicestershire, west by Warwickshire, southwest by Oxfordshire, and southeast by Buckinghamshire, Bedfordshire, and Huntingdon and Peterborough. The area of the geographical county is 915 sq.mi. (2,370 sq.km.) and that of the administrative is 905 sq.mi. (2,344 sq.km.); Northamptonshire is 58 mi. (93 km.) long and almost exactly half as broad at its widest point. Until 1889 it included the Soke (or Liberty) of Peterborough which then became a separate administrative county; after April 1965 the Soke was united to Huntingdonshire to form a new county.

Physical Features.—The underlying structure of the county is very simple. It forms part of the Jurassic escarpment, there known as the Northampton Uplands, which run up to 735 ft. (224 m.) at Arbury Hill near the Warwickshire border. All the rocks are of Jurassic age, the dip being in a general way to the southeast and the strike from southwest to northeast. The oldest and most westerly belt consists of Lias formations which cover a large surface in the southwest and centre, around Banbury (Oxfordshire), Daventry, and south of Market Harborough (Leicestershire), and they are also exposed along the rivers near Towcester, Northampton, Wellingborough, and Kettering. The hard ferruginous marlstones of the Middle Lias were in the past much used for building material, while the Upper Lias is worked for bricks at Raunds, Rothwell, and formerly in many other places. Next above the Lias lie the Northampton sands, important for their iron ore, the county containing one of the largest ironstone fields in Britain; it has been worked mainly in the district north of the Nene between Thrapston and Northampton as far north as Corby, which is now the centre of the principal mining area. Through the middle of the county from the southern border northeast to Northampton, Rockingham, and toward Peterborough, is a wide elevated tract of Oölitic rocks, containing the most famous building freestone of the county, a Lincolnshire Oölite, known as Weldon Stone. The lower beds near the borders of Rutland yield a limestone which splits easily into slabs, known as Collyweston "slates," still quarried for roofing though not so much as formerly. Along the southeastern border of the county a belt of Oxford Clay occupies the surface. Boulder Clay is widely distributed over the uplands and in the east of the county, and glacial and river gravels are also plentiful. At Kingscliffe glacial deposits of high quality silica clay have been worked for several years.

The southwestern portion of the county forms the principal watershed of the Midlands; the Ouse with its tributary the Tove, the Cherwell, the Avon, the Leam, the Welland, and the Nene have their sources in this region. The Nene flows slowly in a northeasterly direction draining to the Wash. In appearance the county is unspectacular; there are no moors or large commons. Apart from the opencast mines and the built-up areas, most of the land is farmed though there are substantial tracts of woodland, relics of Rockingham, Salcey, and Whittlewood forests. The largest of the reservoirs at Pitsford, over 3 mi. long and with a capacity

of 4,635,000,000 gal. (17,550,000,000 litres) was opened in 1956. Other stretches of water have been adapted for sailing and aquatic sports. The county Naturalists Trust controls a wildfowl refuge on Pitsford North Reservoir, as well as part of a disused canal near Passenham and Wicken and a nature reserve in Salcey Forest. The National Trust owns more than 30 ac. (12 ha.) in the county and protects more than 600 ac. (245 ha.).

History.—In primitive times the waters of the North Sea reached almost to the foot of the Northamptonshire Uplands, then covered with dense forest. Paleolithic flint implements have been found in the gravels of the Nene, and there have been a few Neolithic finds. Beaker and other Bronze Age pottery has been found on the uplands. Iron Age A, B, and C cultures are represented and a number of hill forts are known. Hunsbury, 1½ mi. SW of Northampton, is the most famous of these and has yielded a bronze decorated sword scabbard which is an important example of pre-Christian Celtic art, as is a fine bronze mirror from Desborough. The main Roman road, now known as Watling Street, crossed the west of the county and a network of other roads has been traced. Important Romano-British settlements were situated at Towcester, Whilton, Irchester, and probably Kings Sutton. In the 6th century the Middle Angles penetrated up the Nene Valley; in the 7th century Penda, king of Mercia, brought the whole area under his control, and his son Peada founded an abbey at Medeshamstede (now Peterborough) in 655. Foundations also existed at Oundle, Brixworth, and other places, but were destroyed when in 870 the district was overrun by the Danes; Peterborough (*q.v.*) alone was recolonized about 965. The shire is probably of Danish origin, being the area which owed allegiance to Northampton as a military and administrative centre in the 10th century. In 917, when Edward the Elder, after fortifying Towcester, recovered Northampton, this area extended to the Welland, and at the time of the Domesday survey the boundaries approximated to those of the modern county with the addition of the Soke of Peterborough. The Geld Roll (William I) and Domesday Book (1086) mention 28 hundreds in Northamptonshire, part of Rutland being assessed under this county, but by 1316 the hundreds had been reduced to 20, including the hundred of Nassaburgh (Peterborough). At the time of the Domesday survey the chief lay tenant in Northamptonshire was Robert, count of Mortain, whose fief escheated to the crown in 1106. The large estates of William Peverel, founder of the Augustinian abbey of St. James at Northampton, also escheated to the crown in the 12th century. In the 15th century the most famous family was the Wydvilles (Woodvilles), who owned Grafton Regis where Edward IV secretly met and married Elizabeth Woodville in 1464. Other famous families were the Treshams and the Catesbys. Archbishop Henry Chichele was born at Higham Ferrers, and Sir Richard Empson was born at Towcester.

Northampton (*q.v.*), because of its central position and the proximity of its forests in which there were royal hunting lodges, was a favourite meeting place of the councils and parliaments of the Norman and Plantagenet kings. Henry II and Thomas Becket met at Northampton in 1163. In 1215 the barons besieged the castle and in 1264 Henry III captured it from the younger Simon de Montfort. During the Wars of the Roses Henry VI was defeated at Northampton in 1460. In 1607 there was a serious revolt in the county against enclosures of arable land for sheep pastures which had already brought wealth to many county families such as the Spencers and Knightleys. In the Civil War the county declared largely for Parliament, Charles I being defeated at the Battle of Naseby in 1645 and imprisoned at Holdenby in 1647.

From the time of Robert Browne (d. 1633), the independent churchman (buried in St. Giles' churchyard, Northampton), the county has been noted as a centre of Nonconformity. William Carey, the Baptist missionary to India, was born at Paulerspury in 1761, and Dr. Philip Doddridge moved his academy to Northampton when he became independent pastor there in 1729. Thomas Fuller (1608–61) and John Dryden (1631–1700) were born at Aldwinkle and Thomas Percy (1729–1811) was rector at Easton Maudit. The Althorp or Pytchley Hunt (removed to Brixworth in the early 19th century) came into prominence in the second half of the 18th century, as did the Grafton Hunt later.

Northampton's first charter dates from 1189, Brackley's from about 1260, and Higham Ferrers' (*q.v.*) from 1251. From 1547 Brackley returned two members to Parliament, and from 1557 Higham returned one. Under the act of 1832 the county returned four members in two divisions. Under the 1948 act the division of the county and Soke of Peterborough were: Kettering, Peterborough, South Northants, and Wellingborough. The county borough of Northampton also returns one member.

As the archdeaconry of Northampton (mentioned in the 12th century), Northamptonshire was part of the diocese of Lincoln down to 1541 when with Rutland it was separated to become the new diocese of Peterborough. The archdeaconry of Oakham consisting of the northern half of the diocese (including Rutland) dates from 1875. Northampton also gives its name to the Roman Catholic diocese founded in 1850 and covering seven counties.

Architecture.—Of monastic foundations there are no remains of importance. At Geddington and also at Hardingstone, on the outskirts of Northampton, there are Eleanor crosses erected by Edward I. The county is famous for its churches, many with magnificent broached spires. To the Saxon period belong the towers of Earls Barton Church and Brigstock, but the oldest of them all is Brixworth Church built about 675 in the form of a basilica.

Of Norman work, the finest examples are St. Peter's and St. Sepulchre's, Northampton. St. Mary's (Early English and Decorated) in Higham Ferrers is one of the finest churches in the county; those at Irthlingborough and Lowick (with their lantern towers), Warmington (fine Early English work), Rushden, Finedon, Raunds, and Fotheringhay (*q.v.*) should be mentioned. The county is rich in family chapels full of monumental statuary such as those of the Spencers at Brington and the Montagus at Warkton.

Rockingham Castle is now mainly Elizabethan or Jacobean though it was originally built by William I and has a surviving gateway and hall rebuilt by Edward I. Fotheringhay and Northampton castles have disappeared. Barnwell Castle built in 1266 has four round towers and an imposing gateway. Kirby Hall, a beautiful Elizabethan building now a ruin taken over by the Ministry of Works, was once the residence of Sir Christopher Hatton (d. 1591), lord chancellor of England; he also rebuilt Holdenby, which later became a royal residence but was mostly demolished in 1655. Castle Ashby is Elizabethan with a front by Inigo Jones, and Althorp Park dates from the 16th century. Apethorpe Hall, also begun in the 16th century, was the home of Sir Walter Mildmay. The Triangular Lodge at Rushton built (1593–95) by Sir Thomas Tresham, a noted Catholic recusant, is a remarkable allegory of the Trinity. Lamport Hall (National Trust) has a central block designed by John Webb between 1654 and 1657. Boughton House near Kettering is notable for its north facade, the most French looking late-17th-century building in England. Easton Neston is a perfect example of a house by Nicholas Hawksmoor (built 1700–02). Of smaller houses Sulgrave Manor is the ancestral home of George Washington. Northamptonshire, traditionally known as the county of spires and squires, was dubbed the Heralds Garden (1610) by John Norden, the topographer, in reference to its numerous halls and manor houses.

Population and Administration.—The population of the administrative county (1961) was 292,584 (mid-1965 est. 301,640). In 1961 the population of the county borough and county town of Northampton was 105,421 and thus increased to more than 120,000 with the extension of the borough's boundary in April 1965. There are four municipal boroughs, namely Brackley (pop. [1961] 3,208), Daventry (5,860), Higham Ferrers (3,753), and Kettering (38,659). There are nine urban and eight rural districts. The population of Corby in 1961 was 35,938, of Wellingborough 30,583, and of Rushden, 17,377. Corby (*q.v.*), a village in 1931 (pop. 1,596), is a New Town covering 4 sq.mi. (10 sq.km.; not quite coincident with Corby Urban District) with a rapidly growing population estimated in mid-1965 to be 44,610. The court of quarter sessions sits at Northampton and there are nine petty sessional divisions. Northampton has a separate court of quarter sessions. There are 269 civil parishes.

The Economy.—About 84% of the geographical county is farmland. While towns have gradually encroached on farmland, the restoration of land left derelict after opencast ironstone mining has partly restored the balance. During World War II there began a tremendous increase in tillage, maintained and further increased after the war.; by the mid-1960s the figure exceeded 294,000 ac. (119,000 ha.). Cereal crops have increased nearly threefold since 1939 and potato acreage is eight times the 1939 figure. Sugar beet covers above 3,300 ac. (1,300 ha.). The county is best known, however, for livestock rearing, the area of permanent grass, mostly on the hilly uplands, covering about two-fifths of the total farmland. The number of sheep, so important a factor in the county's economy from the 15th to the 18th century, has increased considerably since 1939, and was about 390,000 in the mid-1960s. Important county agricultural shows are held annually at Overstone near Northampton and there is an agricultural institute at Moulton.

The industries of the county are mainly concentrated in a belt of towns along the London-Carlisle road, about Northampton, and in the steel town of Corby where more than 13,000 workers are employed in the huge iron and steel works. Smaller industrial centres are at Brackley, Towcester, and Daventry (radio installations). The chief industries of Northamptonshire include the historically ancient manufacture of boots and shoes and tanning; at Kettering there is a shoe research institute. Engineering is the next most important industry, mainly at Northampton where there are tapered roller bearing, electrical, electronic, and general engineering works. At Northampton and at Kettering the manufacture of clothing is well established; corsets are made at Desborough. Box making and printing, the manufacture of plastic dolls and foodstuffs are among the other industries of the county. At Northampton there is a large brewery. Among older trades now discontinued are lacemaking, of which Wellingborough was a centre, the making of whips formerly carried on at Daventry, of ropes, of clay tobacco pipes at Northampton, of paper in various mills, but especially the weaving of cloth (a staple industry of the county down to about 1800). Agricultural and earth-moving machinery are also made there, and there are firms of vinyl and plastic molders as well as three iron foundries and a large cosmetics factory.

Lying between London and the industrial north, Northamptonshire is traversed by three main railway routes, though, because the gradient down to the Nene was too steep, the main London to Birmingham line, built in 1838, runs a few miles to the west of Northampton. Electrification was completed in November 1965.

In the 18th century Towcester, which lies on Watling Street, and Northampton prospered on their inns. Near Towcester lies Silverstone, a popular centre for motor racing. The Great North Road also touches the county at the western end of the Soke of Peterborough, while the A6 runs through the central industrial belt. The M1 motorway enters the county near Hartwell passing through Watford Gap to Crick, a branch (M45) running west to Coventry and Birmingham. Other main roads run from the Oxfordshire border through Northampton to Stamford via Kettering and to Peterborough via Wellingborough. The former Grand Junction and Grand Union canals pass through this county. There is a small airport at Sywell outside Northampton.

NORTH ATLANTIC TREATY ORGANIZATION

(NATO) was established by the treaty signed on April 4, 1949, in Washington, D.C., by representatives of 12 countries: Belgium, Canada, Denmark, France, Iceland, Italy, Luxembourg, the Netherlands, Norway, Portugal, the United Kingdom and the United States. This list was increased to 14 during the Korean War, when in Feb. 1952, in accordance with the provisions of art. 10, Greece and Turkey acceded to the treaty. Three years later, in May 1955, the Federal Republic of Germany entered the alliance.

Treaty Provisions.—The North Atlantic treaty consisted of 14 articles, the most important of which were art. 6, defining the area to be covered by the treaty; art. 5, the "trigger" clause, setting forth the obligations of the member states if an armed attack should occur within the defined area; and art. 2, providing the basis for political and economic co-operation within the alliance. As modified with the adherence of Greece and Turkey art. 6 explicitly included "the territory of any of the Parties in Europe or North America, . . . the Algerian departments of France . . . the territory of Turkey or . . . the islands under the jurisdiction of any of the Parties in the North Atlantic area north of the Tropic of Cancer." Within this vast expanse, far greater of course than the North Atlantic plus western Europe, the parties agreed (under art. 5) that "An armed attack against one or more of them . . . shall be considered an attack against them all; and consequently they agree that, if such an armed attack occurs, each of them, in exercise of the right of individual or collective self-defense recognized by Article 51 of the Charter of the United Nations, will assist the Party or Parties so attacked by taking forthwith, individually and in concert with the other Parties, such action as it deems necessary, including the use of armed force to restore and maintain the security of the North Atlantic area."

The hope of the members that the treaty would transcend the essentially defensive, military features of art. 5 was expressed in art. 2: "The Parties will contribute toward the further development of peaceful and friendly international relations by strengthening their free institutions, by bringing about a better understanding of the principles upon which these institutions are founded, and by promoting conditions of stability and well-being. They will seek to eliminate conflict in their international economic policies and will encourage economic collaboration between any or all of them."

The treaty formally and definitively recognized that a brief chapter of world history had ended, a chapter which had been marked by a European and American coalition with the Soviet Union to defeat the Axis powers in World War II and establish a new international order after that defeat. Soviet action inside the United Nations had forced the west to the conclusion that the international organization could not in and of itself maintain peace and security. The swiftness with which the Soviet Union converted eastern European countries from German satellites into Communist puppets indicated that Russia was bent on external expansion. Above all, the Communist *coup d'état* in Czechoslovakia in 1948 and the breakdown of the four-power control commission in Germany posed for western statesmen a threat to their national security and independence.

Preliminary Steps.—Preservation of free institutions in Europe after World War II required three types of action. First was the elimination of Communists from the ministries of certain European countries and the isolation if not the reduction to impotence of the various national Communist parties, avowedly instruments of Soviet design and tools of Soviet policy. In 1947 this step had been taken in France and Italy, the two countries with the largest Communist parties; in the rest of western Europe by that time Communist organizations could not undertake successful programs of subversion or insurrection. The second requisite was co-operation among European nations, since individually each was patently incapable of defending itself against the Communist colossus. A beginning in this direction was made with the establishment in 1948, as the European co-ordinating agency for the European Recovery program (E.R.P.), of the Organization for European Economic Cooperation (O.E.E.C.). More significant as forerunner of the North Atlantic treaty was the Brussels pact (a 50-year mutual defense alliance), signed in March 1948 by Belgium, the Netherlands and Luxembourg (the so-called Benelux countries), France and the United Kingdom just one month after the Communists seized control of Czechoslovakia.

In the third place, however, western European countries, even united and determined to remain outside the enlarging Soviet orbit, could attain their objective only if North America threw its weight into the balance. Under the Marshall (E.R.P.) plan, the United States in 1948 had undertaken a multibillion-dollar program of economic assistance, but military aid and political commitments were also needed if the Soviet Union was to be convinced of the folly of further European aggrandizement. For Canada as a member of the British Commonwealth such a commitment followed most logically upon the close involvement of the mother country in continental affairs after World War II, beginning with the Dunkerque treaty with France in 1946. Canada was therefore a leader in arguing for a broadening of the Brussels pact to include North America.

United States membership in a military alliance in peacetime represented a sharp break with the nation's former policies of neutrality and isolation. The United States had joined with the other American republics of the western hemisphere in the Inter-American Treaty of Reciprocal Assistance (Rio treaty), which became a prototype of the North Atlantic treaty in its self-defense aspects. (*See* PAN-AMERICAN CONFERENCES.) Bipartisan leadership proceeded to use the Rio treaty as the precedent for United States membership in "such regional and other collective arrangements as are based on continuous and effective self-help and mutual aid." These words from the Arthur S. Vandenburg resolution adopted by the U.S. senate in June 1948 clearly indicated the increasingly favourable disposition of the United States toward a North Atlantic treaty soon to be negotiated.

From Pact to Organization.—Some time passed after the signing of the 1949 treaty before the North Atlantic treaty became an organization. The transition was accelerated by North Korea's attack on South Korea in June 1950, which was interpreted to mean that international Communism would not shrink from overt military aggression anywhere in the world, including Europe, where weakness and indecision seemed to provide favourable opportunities.

The key to the organization that developed was the relationship between two complexes of committees, one civilian and one military. Periodic meetings of foreign and defense ministers of the signatory powers attracted the major share of public attention, but the cardinal element in the political control of the organization was the North Atlantic council, on which representatives of the member states sat in theoretically permanent session. Individual meetings of the council could be informal, with no agenda and no record of decisions, or could entail the presence of selected advisers to the delegates for the discussion of particular problems. The size of the organization and the increasing range of subjects considered by the council made the work of the secretary-general and his staff very important. To balance the prominent role played by U.S. representatives on the various military committees the secretary-general was chosen from among the other countries. Lord Ismay of the United Kingdom was succeeded by Paul Henri Spaak of Belgium, followed in turn by Dirk U. Stikker of the Netherlands. Working under the direction of the secretary-general was an international staff secretariat that gradually increased in size. A highly important factor in the long-term viability of the organization was the growing consciousness of the members of the secretariat that they were to function as international civil servants; they were to reflect the views of the organization. not primarily the views of their own governments. The North Atlantic council had several civilian committees, perhaps the most significant of which were those concerned with infrastructure (the network of installations supporting the military capability of the organization) and the annual review committee, whose function it was to survey the military programs of the member governments to determine the adequacy of their contributions to the organization and the forces which they might justly be called upon to maintain at the disposal of the NATO commanders.

Responsible within the organization to the North Atlantic council was the complex of military committees, at the head of which was the military committee itself. A noteworthy subsidiary was the standing group, meeting in Washington and composed of British, French and United States representatives whose task it was to provide advice co-ordinated among the three senior nations of the alliance.

Also beneath the military committee were the various regional commands into which the area covered by the treaty was divided. Of these commands the supreme allied commander in Europe (SACEUR) was so important, by reason of the central continental area for whose defense he was responsible, as to overshadow, at least in the popular view, the other commands which were administratively on the same level. It was to this critical zone that most of the U.S. ground and air forces were assigned. SACEUR began to emerge with the appointment late in 1950 of Gen. Dwight D. Eisenhower of the United States as its head; he was followed by three other U.S. generals, Alfred M. Gruenther, Lauris Norstad and Lyman L. Lemnitzer. As in the case of other commands, including most prominently the supreme allied commander Atlantic (SACLANT), with headquarters in Norfolk, Va., SACEUR was in turn divided regionally into subordinate forces for northern, central and southern Europe and for the Mediterranean. On the European continent another division was by the type of forces involved—land, sea and air.

Problems of Co-ordination.—Not without difficulty were arrangements for defense actually made. While recognizing the necessity for co-operation, nations were understandably reluctant to accept subordinate positions in areas which for centuries they had individually fought to defend—often against nations that were now their partners in NATO. Where overlapping interests threatened to conflict, as in the Mediterranean, compromise arrangements were hammered out in lengthy political sessions. Once established, distributions of command positions were difficult to change in recognition of shifting national responsibilities. In the Mediterranean, for example, both France and Italy felt that their developing requirements for national defense should be reflected in organizational arrangements. It was, furthermore, easier to advance the principle of national concentration on particular weapons and forces than it was in practice to induce nations to abandon portions of their military establishment. The limited standardization of matériel that developed resulted less from explicit decision on the part of the organization than from the burden of national defense expenditures and the co-operation among private manufacturers in western Europe and North America. Equality of sacrifice was another principle that was accepted by all members of the organization in theory but could not be reduced to concrete mathematical formulas for sharing defense costs. Increasing prosperity did not make most member states any less loath to increase the military proportion of their budgets, even to meet specific threats such as that posed by the crisis over West Berlin. Disruptive disputes on these questions could be avoided because the United States shouldered the largest burden of military responsibility. At the same time there was a rapid increase in West German military might, and there were recurrent actions of the Soviet Union that reminded all members that some compromise of national independence was necessary to meet the continuing threat.

Problems of Implementation.—Of even greater seriousness were three other political-military problems: (1) the number and type of forces that the allies could and should raise, (2) the nature and size of contribution that the Federal Republic of Germany should make and (3) the degree of involvement of U.S. forces and weapons in the organization.

1. After the outbreak of the Korean War military estimates placed at more than 90 the number of conventionally armed divisions needed in western Europe to deter and defeat a Soviet attack. It immediately became apparent that NATO nations could not and would not come close to this level. The large gap between what ought to be done and what would be done forced the acceptance of an increased element of risk; force goals were adopted that were only slightly more than half as large as originally established.

In 1954 a step of long-lasting significance was taken with the announcement that NATO forces would not hesitate to use nuclear weapons to defend western Europe even if the Soviet attack at

first employed only conventional arms. One purpose of NATO's conventional forces thus came to be the deterrence of attack by confronting the Soviet Union with the necessity of mobilizing considerable power for any advance. Another purpose would be to give the western allies time to reflect on whether the use of nuclear weapons, with all the dangers entailed, was indispensable to their self-protection. Although about 30 divisions was the stated minimum required for the concept of deterrence and defense, European nations displayed continued reluctance to raise their allotted number in strength and readiness. Still subject to debate was the feasibility of avoiding thermonuclear holocaust once even small-yield atomic weapons had been employed by either side.

2. Into this problem of the number and type of forces needed to defend western Europe the question of the German Federal Republic intruded. From the very outset the logic of defense dictated a "forward strategy" or concentration of forces in West Germany. Economic and political decisions made by western European nations, when measured against the units available to the Soviet Union for any attack, pointed increasingly to the necessity of a German military contribution. However, for some countries, particularly France, which had welcomed German cooperation in European political and economic institutions, the reconstruction of a German army symbolized in an obvious, grievous way the decline of their power and prestige before the historical European malefactor. Four years passed after Sept. 1950, when the United States first pressed for a German military contribution, before France, under the arrangement known as the Western European Union, accepted German membership in NATO and the right of Germany to a military establishment. In the interim, French opposition finally destroyed the formula for subordination of German units to a supranational military and political control as embodied in the European Defense and European Political Communities (E.D.C. and E.P.C.) respectively. Restraints on Germany still existed in the agreement within the Western European Union that Germany should produce some weapons, notably naval vessels and missiles only in limited size and quantity and should manufacture no atomic, biological or chemical weapons at all. The growing dependence of the organization on German forces for defense against Soviet threats, especially to West Berlin, added to NATO's decision to use weapons of mass destruction if necessary, and the inexorable, if slow, spread of nuclear technology loosened these unilateral restrictions to such an extent that the remaining ones seemed more illusory than irksome.

3. The United States was the key element in both these problems. It obviously was not disposed, even if it were able, to bridge the gap alone between available and needed western forces. Moreover, domestic legislation prevented the United States from transferring nuclear weapons to custody of another country or of providing information on their manufacture to allies who had not demonstrated their ability to produce such weapons without assistance. This position, in addition to making a German contribution more urgent, also profoundly influenced the operating principles of NATO. Nuclear weapons "assigned to NATO" would be guarded by United States forces and would pass into foreign hands only after a Soviet attack had taken place. Protracted French efforts to develop a limited form of independent nuclear power emphasized that the main deterrent to Soviet aggression remained in Anglo-American hands, with neither the British bomber command nor the United States strategic air command subject to orders from the organization in times of peace. When, after 1958, the Soviet Union was able to threaten the territory of the United States directly, European countries professed uneasiness over whether the leader of the alliance would, if worse came to worst, throw its forces into the defense of the continent at the almost certain cost of millions of casualties at home. Suggestions for increasing allied confidence in the binding nature of the treaty included creation of national nuclear forces or the pooling of substantial atomic power under direct control of the organization.

Significance.—NATO was designed primarily as an instrument of military defense in the immediate postwar era, which was characterized by a Soviet military threat to western Europe and by a U.S. preponderance of nuclear military power. With the passage of time the balance of east-west military power shifted and European economic dependence on the United States greatly declined. In the structure of western cooperation, which included such institutions as the Organization for Economic Cooperation and Development, the European Economic Community (better known as the Common Market) and the European Atomic Energy Community (Euratom), NATO continued to be important, but it no longer dominated the interallied scene. Affected by nonmilitary relations, NATO nonetheless did not venture far beyond the strict confines of European defense. Habits and machinery for political consultation were broadened and improved under the shock of the abortive invasion of the Suez area in 1956 by British and French troops. But in this function NATO was clearly assisting the ways of traditional diplomacy rather than adding organizational devices for formal conciliation or settlement. The enduring strength of the organizations also depended in large part on solutions to problems in which NATO countries were involved outside the geographical area formally covered by the treaty, as in the case of France in Africa, Portugal in Africa and Asia and perhaps the United States in relation to Communist China. Clearly the security of the alliance rested on more than the military forces it was able to mobilize in Europe, the Mediterranean and the Atlantic.

During the early 1960s, the French government, under the leadership of President De Gaulle, exhibited a growing disenchantment with NATO and a determination to develop its own independent military force. French leaders had for some time been expressing their dissatisfaction with the NATO military structure, which placed primary reliance upon U.S. troops and U.S. nuclear power. In 1960 France had become the fourth world power to produce and test a nuclear device; it also had under way a program to build up a bomber striking force. In March 1966 the French government, holding that the conditions that had brought about the formation of the alliance in 1949 no longer existed, notified the other NATO members that it would withdraw its troops from the NATO defense system by July 1, 1966; it also requested the removal, within a year, of the NATO military headquarters and of U.S. and Canadian troops and bases from French soil. France did not denounce the 1949 treaty, which provided that no member could withdraw for 20 years, but stated it would fight at the side of the allies in case of unprovoked attack during the following three years.

The physical shifting of NATO's military and political headquarters from Paris to Brussels, begun in 1966, coincided with profound changes in the nature of the alliance. In view of the growing *détente* with the U.S.S.R., apparent since 1963, NATO ministers' consultations increasingly emphasized strictly European issues—especially those bearing upon aspirations for economic unity—rather than military deterrence. On these new grounds and in the absence of France, Germany took the lead in broad policy-making in NATO; the U.S., occupied with Asia and a limited participant in Europe's affairs once the mutual-defense motive had been subordinated, no longer exercised the kind of influence that brought the alliance into being.

NORTH BAY, a city of Ontario, Can., and the seat of Nipissing district, is on the northeast shore of Lake Nipissing. It serves as a dividing point between northern and southern Ontario, hence its popular description "gateway of the north." For many years it was best known as a railway centre and distributing point, and tourism is important. North Bay is the site of a large all-weather jet air base. Pop. (1966) 23,115; Greater North Bay, including the adjacent townships of Widdifield and West Ferris, about 45,000. (C. M. FE.)

NORTH BORNEO (SABAH): *see* MALAYSIA.

NORTHBROOK, THOMAS GEORGE BARING, 1ST EARL OF (1826–1904), English statesman and viceroy of India, was born in London on Jan. 22, 1826, the eldest son of Sir Francis Baring (afterward 1st Baron Northbrook). He was educated at Christ Church, Oxford, and was brought up in an atmosphere of Whig politics. After gaining extensive experience as private secretary to several statesmen and as a junior minister, he became undersecretary of state for war in 1861 and again in the Gladstone ministry of 1868, and was appointed viceroy and governor general of India in 1872. He followed a policy of financial economy, and in 1875 succeeded in lowering the general level of import duties from 7½% to 5%. But his relations with the home government deteriorated after the Liberal duke of Argyll was succeeded as secretary for India by the Conservative Lord Salisbury with the return of the Disraeli ministry to power in 1874. When Salisbury urged the remission of the import duty on Lancashire cotton piece goods, Northbrook declined for, although he believed in the principles of free trade, he thought that the duty was justified by the revenue it produced and that Indian opinion would be scandalized by any idea that India's interests were being sacrificed to Lancashire's. He also disagreed with Salisbury's proposal to station a British agent at Herat despite the opposition of the amir of Afghanistan. Finally, in 1876, Northbrook resigned on personal grounds, and was given an earldom. He served as first lord of the admiralty in the Gladstone ministry of 1880–85, and went to Egypt in 1884 as special commissioner to inquire into financial problems. He died at Stratton park, Hampshire, on Nov. 15, 1904.

(KE. A. B.)

NORTH CAROLINA, popularly known as the "Tar Heel state" and the "Old North state," one of the original 13 states, the 12th to ratify the constitution, is located in the southeastern part of the United States. It is bounded on the north by Virginia, on the east and southeast by the Atlantic ocean, on the south by South Carolina and Georgia and on the west and northwest by Tennessee. North Carolina has an extreme length from east to west of 503¾ mi., which is greater than that of any other state east of the Mississippi river. Its total area is 52,712 sq.mi., of which 3,615 sq.mi. are water surface; in size it ranks 28th among the states. The name Carolina ("land of Charles") was first used in 1629 in honour of Charles I of England. The capital of the state is Raleigh (*q.v.*), named in honour of Sir Walter Raleigh. The North Carolina state motto is *Esse quam videri* ("To Be Rather Than to Seem"). The flag has a blue union containing a white star and the letters "N" and "C," the star surmounted by a scroll bearing the inscription "May 20th, 1775" (the date of the Mecklenburg declaration of independence), and below the star another scroll inscribed "April 12th, 1776" (the date of the Halifax resolution); the fly consists of two equal bars of red and white. The state bird is the cardinal, the flower the dogwood and the song "The Old North State."

PHYSICAL GEOGRAPHY

Physical Features.—The state (between latitude 33° 52′ and 36° 34′ N., and between longitude 75° 27′ and 84° 20′ W.) lies wholly within the three leading topographical regions of the eastern portion of the United States: the Coastal plain, which occupies approximately the eastern half; the Piedmont plateau, which occupies about 20,000 sq.mi. in the middle; and the Appalachian mountain region, which occupies about 6,000 sq.mi. in the west.

Coastal Plain.—At the eastern extremity of the Coastal plain region an outer coast line is formed by a chain of narrow sandy islands, known as the Outer banks, from which project capes Hatteras, Lookout and Fear, whose outlying shoals are known for their difficulty of navigation. Between Hatteras and Lookout is Raleigh bay and between Lookout and Fear is Onslow bay; and between the chain of islands and the deeply indented mainland Currituck, Albemarle (*see* ALBEMARLE SOUND), Croatan, Pamlico, Core and Bogue sounds form an extensive area, especially to the northward of shallow, brackish and almost tideless water. Projecting into these sounds and between the estuaries of rivers flowing into them are extensive tracts of swampland, the best known of which is the Dismal Swamp (*q.v.*), which lies mostly in Virginia and is about 37 mi. long and 22 mi. wide. The Coastal plain contains many natural lakes, the largest of which are Mattamuskeet, Waccamaw, Black and Phelps. Through most of the region, which extends inland an average of 150 mi., the country continues very level or only slightly undulating, and rises to the westward at the rate of little more than one foot to the mile. The Fall line, the boundary between the Coastal plain and the Piedmont plateau, has a very irregular course across North Carolina, but lies in a general southwesterly direction from the Falls of the Roanoke between Halifax and Northampton counties to Anson county on the South Carolina border; it marks a rapid increase in elevation of about 200 ft.

Much of the land near the coast is low and swampy, but the western part of the Coastal plain has much fertile soil, chiefly sand silt loams. This is the largest and best farming area in the state, the place where much of the nation's bright-leaf tobacco is grown as well as a great variety of other crops. The Sandhills area in the vicinity of Pinehurst and Southern Pines, at the western edge of the Coastal plain, is famous as a winter resort and as a peach-producing area. The chief rivers in the Coastal plain are the Roanoke, Chowan, Tar-Pamlico, Neuse-Trent and Cape Fear. With the exception of the Cape Fear, which empties directly into the ocean, all of these rivers flow into the sounds, which are shallow and not very good for navigation and trade. Wilmington (*q.v.*), the state's leading deep-water port, is situated on the Cape Fear river.

Piedmont Plateau.—North Carolina has the largest Piedmont plateau area of any of the eastern states. This region extends from the Fall line westward to the Blue Ridge escarpment, toward which its mean elevation increases at the rate of about 3½ ft. to the mile. This gently rolling country ranges in elevation from about 400 ft. in the Durham area to 1,500 ft. in the Morganton vicinity. The chief rivers of the Piedmont are the Yadkin (Pee Dee-Yadkin), Catawba and Broad. The Piedmont rivers, being shallow and swift and having many waterfalls, are not good for navigation but are excellent for the development of power. Textiles, tobacco and furniture manufactures first developed in the Piedmont, and this region remains the centre of North Carolina manufacturing.

Appalachian Mountains.—The third physical division in the state is the mountain region, a part of the Appalachian system. There are two large chains of mountains, the Blue Ridge (*q.v.*) on the east and the Great Smoky mountains (*q.v.*) on the west. Connecting these two chains are several cross ridges. One of these, the Black mountains, contains Mt. Mitchell (6,684 ft.), the highest peak in the eastern part of the United States. The state has the largest mountain area in eastern America. In the "Land of the Sky," as this beautiful region is sometimes called, there are 43 peaks of over 6,000 ft. and 125 others of more than 5,000 ft. The mountain valleys are usually narrow and deep, though few descend to less than 2,000 ft. above sea level. The beautiful scenery, pleasant climate and good roads have made this region one of the great summer resorts of the nation.

From the Black mountains, the streams flow as from a ridge pole, some to the Atlantic, others to the Mississippi and finally to the Gulf of Mexico. West of the Blue Ridge the Hiwassee, the Little Tennessee and the French Broad rivers flow west or northwest into Tennessee. Farther north are the headwaters of the New river, which finds its way to the Ohio. On the southeastern slope of the Blue Ridge rise the Broad, the Catawba and the Yadkin, which first flow northeast, then, finding a passage across one of the ridges of the Piedmont plateau, turn to the southeast and across the boundary line into South Carolina, in which state their waters reach the Atlantic.

Climate.—The climate of North Carolina varies from that of the southeast corner, which approaches the subtropical, to that of the mountain region, which is like the medium continental type except that the summers are cooler and the rainfall greater. The mean annual temperature for the state (below an elevation of 4,000 ft.) is about 59° F. (about 15° C.); for the Piedmont plateau

region, 60° F.; for Southport, in the southeast corner of the state, 64° F.; and for Highlands, at an elevation of 3,817 ft. in the southwest corner, 50° F. Extremes have ranged from −19° F. (about −28° C.) at Highlands to 107° F. (about 41° C.) at Chapel Hill, Orange county. The average precipitation for the state is about 50 in. a year, nearly all of it in the form of rain. For the Coastal plain region it is 48 in.; for the Piedmont plateau region 47 in.; and for the mountain region 54 in. On the east slope of some of the mountains the rainfall is exceedingly heavy. The winds are variable and seldom violent, except along the coast during the subtropical storms of late summer and early autumn.

Soil.—In the Coastal plain the soil is generally sandy, but in all parts of this region more or less marl abounds; south of the Neuse river, the soil is mostly a loose sand, north of it there is more loam on the uplands, and in the lowlands the soil is usually compact with clay, silt or peat; toward the western border of the region the sand becomes coarse and some gravel is mixed with it. The entire Piedmont region is underlain by crystalline rocks, such as granite and schists. The soils are, for the most part, red sandy loams, gravelly and sandy in spots.

Vegetation.—The growing season, free from killing frost, ranges from 240 days along the coast to 200 in the mountains. Because of its great variety of climate and soils, North Carolina has the greatest variety of plant life of any state in eastern North America. Tree species range from subarctic spruce and balsam fir in the high mountains to subtropical palmetto in the Wilmington-Southport area. North Carolina is one of three states having the greatest variety of hardwoods. It is the second largest lumber producing state in the south and the fifth largest in the nation. Pines are found throughout the state, especially in the east. Near the coast grows the carnivorous Venus's-flytrap.

Animal Life.—Among the most prevalent wild animals are rabbits, squirrels, raccoon, opossum, deer, bear, muskrats, foxes and wildcats. The commonest birds are cardinal, wren, mockingbird, chickadee and also many varieties of woodpeckers and warblers. Quail, doves, robins, wild turkeys, geese and duck also are plentiful. Many migratory game birds winter in North Carolina and swans, geese and ducks nest near the coastal waters.

Inland-water fish such as bluegills, crappies, bass and sunfish are found in many ponds and lakes throughout the state. Brook and rainbow trout also thrive in the mountain streams. Shad, herring, croakers and many other varieties of fish are to be found in the sounds and other waters of eastern North Carolina. Oysters, clams, shrimp and scallops are abundant along the seaboard.

State and National Parks, Historic Sites, Forests and Game Refuges.—By the early 1960s the state had acquired and developed almost a score of parks and recreational areas, among which are Mount Mitchell, Fort Macon near Beaufort, Hanging Rock in Stokes county, Morrow Mountain in Stanly county, Cliffs of Neuse in Wayne county, William B. Umstead park in Wake county, Town Creek Indian mound in Montgomery county and Tryon's palace at New Bern.

The United States government contributed greatly to recreational development by the creation of four large national forests—Pisgah and Nantahala in the mountains, Uharie in the Piedmont and Croatan in the Coastal plain. It also established the Great Smoky Mountains National park (*q.v.*), containing about 500,000 ac. in North Carolina and Tennessee. National military parks and historic sites are Guilford Courthouse (near Greensboro), Moores Creek (near Wilmington), Fort Raleigh (at Roanoke Island) and Wright Brothers National memorial (at Kitty Hawk). The Cape Hatteras National Seashore recreational area, established in 1953 and comprising 28,500 ac. in public beach and dune lands, was the first such area in the national park system.

HISTORY

The history of North Carolina may be divided into four main periods of unequal length and significance: the period of discovery and early colonization (1524–1663); the period of proprietary rule (1663–1729); the period of royal rule (1729–76); and the period of statehood (from 1776).

Discovery and Early Colonization.—The first Europeans to explore the coast of North Carolina were the French led by Giovanni da Verrazano in 1524. Two years later, Lucas Vazquez de Ayllón led a Spanish expedition from Santo Domingo and planted a temporary colony of over 500 people near the mouth of the "Rio Jordan," probably the Cape Fear. In 1540 Hernando de Soto's expedition from Florida penetrated the mountains of North Carolina before turning west and discovering the Mississippi river. Neither the French nor Spaniards made further efforts to colonize this region.

It was the English who permanently colonized and held North Carolina. After receiving from Queen Elizabeth I a patent for colonization in the new world, Sir Walter Raleigh in April 1584 sent Philip Amadas (or Amidas) and Arthur Barlowe to discover a suitable site for a colony bordering on Florida, then in the possession of Spain. Amadas and Barlowe returned in September with a glowing account of the coast of North Carolina, and on April 19, 1585, a colony of 108 men under Ralph Lane sailed from Plymouth in a fleet of seven small vessels commanded by Sir Richard Grenville. The colony was established at the north end of Roanoke Island on Aug. 17 and about a week later Grenville returned to England for supplies. Threatened with famine and with destruction by hostile Indians, the entire colony left for England on June 19, 1586, on Sir Francis Drake's fleet. Only a few days after their departure Grenville arrived with supplies and more colonists, 15 of whom remained when he sailed away. Although greatly disappointed at the return of the first colony, Raleigh dispatched another company, consisting of 121 persons under John White, with instructions to move the plantation to the shores of Chesapeake bay. The new company arrived at Roanoke Island on July 22, 1587, and were forced to remain there by the refusal of the sailors to carry them farther. Of the 15 persons left by Grenville not one was found alive. White's granddaughter, Virginia Dare (b. Aug. 18, 1587), was the first English child born in America.

Governor White soon returned to England for supplies, and having been detained there until 1590 he found upon his return no trace of the colony except the word "Croatoan" carved on a tree hence the colony was thought to have gone to friendly Indians of that name. The fate of the "Lost Colony" has remained one of the mysteries of history (*see* ROANOKE ISLAND).

Geographical conditions determined that the first permanent settlement of North Carolina was from Virginia rather than from Europe directly. The first permanent English settlement in America was made at Jamestown, Va., in 1607. Within a relatively short time people from this settlement were beginning to explore what is now northeastern North Carolina, and the area was also beginning to attract attention in England. In 1629 King Charles I granted Carolana (Carolina) to Sir Robert Heath, who did not succeed in planting a colony. The region north of Albemarle sound was first settled in the 1650s, probably as early as 1653, by persons moving south from Virginia in quest of good farm land. This settlement attracted attention in England, where a group of courtiers applied to Charles II for a patent to the territory south of Virginia including the Albemarle settlements.

Proprietary Rule.—In 1663 Charles II granted the territory between the 31st and 36th parallel, and extending from sea to sea to the earl of Clarendon, the duke of Albemarle and six other favourites. These were the same boundaries as those in the Heath patent, which was now declared void because of failure to settle. By a second charter issued to the eight lords proprietors in 1665 the limits of Carolina were extended to 29° and 36° 30′. The proprietors established Albemarle county and divided it into precincts which chose representatives to an assembly which, with the court system, council and governor appointed by the proprietors, constituted the government. The first assembly met in 1665. In 1669 the proprietors adopted the Fundamental Constitutions of Carolina, written by John Locke, but this elaborate and feudalistic form of government failed to work and was eventually dropped. The proprietors failed to give Albemarle county competent officials or a stable, efficient government, and the colony grew slowly. The hardy, individualistic settlers drove several incompetent governors from office. Albemarle county ceased to exist by that name in 1689 when the proprietors appointed Philip Ludwell

governor of "that part of our Province of Carolina that lies north and east of Cape Fear." Two years later a reorganization of government provided for a governor of all Carolina, resident at Charleston, who should rule the northern settlement through a deputy. From 1712 until 1729 the proprietors appointed governors to rule "North Carolina" as a separate province, though the boundary between North Carolina and South Carolina was not agreed upon until 1735 nor fully surveyed until 1815. The North Carolina-Georgia boundary was not surveyed until 1819.

Settlers had troubles with the nonresident proprietors over quitrents and other matters relating to land tenure; with Virginia, which forbade shipment of Carolina tobacco through its ports and disputed over the boundary until its joint survey in 1728; and with England, whose trade regulations and taxation of tobacco led to Culpeper's rebellion in 1677. In 1708 the Cary rebellion broke out because of the taxation of Quakers and other dissenters for support of the established church. The colony suffered heavily from the Tuscarora War (1711–13) and was able to defeat Tuscarora (*q.v.*) only by timely military aid from South Carolina. The trade of the colony suffered from pirates who frequented the coast, and the governors made little effort to stamp out piracy. This handicap to commerce was practically removed in 1718 when an expedition from Charleston captured Stede Bonnet and when another expedition from Virginia killed Edward Teach, commonly known as Blackbeard.

Owing to all these troubles and to inadequate transportation facilities, North Carolina's growth was extremely slow. All the other English colonies began with the founding of towns, but North Carolina had no town until after 1700. Bath, the oldest town in the state, was settled by French Huguenots from Virginia and was incorporated in 1706. In 1710 New Bern (*q.v.*) was settled by Swiss and Germans. In 1722 a village on Queen Anne's creek was named Edenton in honour of Gov. Charles Eden. Beaufort was begun about the same time. About 1727 Brunswick was laid out on the lower Cape Fear by Maurice Moore of South Carolina, and the attractive and fertile valley of the Cape Fear with its superior navigation was settled quite rapidly. Newtown, incorporated as Wilmington in 1739, soon became the chief port. The estimated population of the colony at the close of the proprietary era was 35,000; they covered the area from Virginia southward beyond the Neuse river and in the Cape Fear valley.

Royal Rule.—In 1729 North Carolina became a royal colony when King George II purchased the shares of seven of the eight lords proprietors for £17,500, plus £5,000 for arrears in quitrents. Lord Carteret, later earl of Granville, refused to sell, and a strip of land in North Carolina lying between latitude 35° 34′ and the Virginia line (36° 30′), known as the Granville district, was laid off as his one-eighth share of Carolina. Granville held the land in this area and collected quitrents, but he had no governmental jurisdiction. His land policy in the Granville district was a source of serious friction with inhabitants, and his ownership of the land deprived the colonial government of badly needed revenue.

The passage of North Carolina to the crown caused no significant change in governmental structure or powers, though it brought the colony more closely into line with British imperial administration. Royal government was characterized by greater stability, stronger administration and better enforcement of law and order than had prevailed under the proprietary regime. The transfer of the province to the crown marked the beginning of a significant era in North Carolina—its first real period of progress. The history of the colony for the next 40 years was characterized by a steady and rapid growth in population; settlement of the whole Cape Fear valley and the Piedmont; expansion of agriculture, industry and trade; some improvements in transportation and the beginnings of a postal system; a higher standard of living, reflected in better homes, finer furniture, more and better tools and implements and more comfortable living conditions; rapid growth of dissenting sects, notably Presbyterians and Baptists; and founding of many churches, a few schools and some libraries.

As settlement expanded many new counties and towns were founded, among the latter being Halifax, Campbellton (present Fayetteville; *q.v.*), Hillsboro, Salem, Salisbury (*q.v.*) and Charlotte (*q.v.*). There was a great increase in the production and trade of tobacco, naval stores (tar, pitch, turpentine and rosin) and rice with England, New England and the West Indies. The first printing press was set up at New Bern in 1749, and two years later appeared the first book and the first newspaper, the *North Carolina Gazette*, edited by James Davis, the public printer.

During the royal period, Scotch-Irish, Germans, Highland Scots, English and a few other national stocks poured into North Carolina. Between the battle of Culloden (1746) and the American Revolution, perhaps 20,000 Highland Scots settled in the Cape Fear valley, comprising the earliest and largest settlement of Highlanders in America. About 65,000 Scotch-Irish, who came largely by way of Pennsylvania, and 25,000 Germans (Moravian, Lutheran and Reformed), also by way of Pennsylvania, settled throughout the Piedmont counties. Negro slaves increased from 6,000 to more than 40,000, being found mostly on eastern plantations engaged in the production of tobacco, rice and naval stores. The population of 35,000 in 1729, confined to the Coastal plain, increased to nearly 300,000 in 1775 and extended from the coast to the Blue Ridge mountains and to the Watauga-Holston valleys beyond. When North Carolina became an independent state in 1776, about one-third of its people were of English stock; nearly one-third were Scottish, either Highlander or Scotch-Irish; one-fifth were Negroes; and about one-tenth were Germans.

Geographic, ethnic, economic, social and religious differences produced a deep-seated east-west sectionalism. The colonial government was dominated by the east, and even county government was controlled by the royal governor through his power to appoint local officers. County officials were often corrupt, inefficient and oppressive. The back country people suffered from excessive taxes, dishonest officials and exorbitant fees. They also complained bitterly about multiple office holdings. An association called the Regulators sought vainly to obtain reforms. Then they refused to pay taxes and fees, punished public officials and interfered with the courts. The Regulation insurrection ensued, in which the insurgents were crushed by Gov. William Tryon, who later became colonial governor of New York, with the support of the eastern-dominated government at the battle of Alamance, May 16, 1771.

The political history during the royal period is, like that of other colonies, the story of a constant struggle between representatives of the people and representatives of the crown. There were bitter disputes over questions of government, trade, finance and religion. In 1765–66 armed patriots prevented the enforcement of the Stamp act in the colony. The people formed associations pledged not to purchase British goods in protest against the import duties levied under the Townshend act of 1767. In 1774 they sent aid to Boston after its port was closed by the British following the Boston Tea Party.

In Aug. 1774 the first provincial congress met at New Bern in defiance of Gov. Josiah Martin and elected delegates to the first Continental congress. A second provincial congress met in April 1775, and in the next month royal rule ended in North Carolina when Governor Martin fled from New Bern to a British ship in the Cape Fear river. A committee representing the militia companies of Mecklenburg county on May 31, 1775, adopted a series of resolutions which declared that the royal commissions in the several colonies were null and void, that the constitution of each colony was wholly suspended and that the legislative and executive powers of each colony were vested in its provincial congress subject to the direction of the Continental congress; and the resolutions requested the inhabitants of the county to form a military and civil organization independent of the crown of Great Britain which should operate until the provincial congress should otherwise provide or the British parliament should "resign its unjust and arbitrary pretensions with respect to America." The Mecklenburg declaration of independence, which it is alleged was passed on May 20 by the same committee, is of doubtful authenticity, though the date appears on the state flag by legislative act. The Whig (patriot) victory at Moores Creek bridge, Feb. 27, 1776, thwarted Governor Martin's efforts to re-establish royal authority.

Independence.—The first sanction of independence by any

colony was the Halifax resolution adopted by the fourth provincial congress on April 12, 1776, and the same body immediately proceeded to the consideration of a new and permanent form of government. Their labours ended, however, in another provincial government by a council of safety, and the drafting of North Carolina's first state constitution was left to a constitutional convention that assembled on Nov. 12, at Halifax.

In the American Revolution, North Carolina furnished ten regiments of Continental troops and many thousands of militia. It sent military aid to South Carolina and Virginia and to Washington's army in the north, while it also helped to defeat the Cherokees and suppress the numerous Tories who made the revolution a civil war in North Carolina. A British invasion was turned back on Oct. 7, 1780, by the destruction of Maj. Patrick Ferguson's army at King's mountain. Cornwallis' invasion of the state culminated in the battle of Guilford Courthouse on March 15, 1781. Though it was a technical British victory, Cornwallis retreated to Wilmington from where he marched north to his fate at Yorktown.

Statehood.—During the confederation, 1781–89, North Carolina, like other states, met its federal obligations to the central government only when it wished to do so. The state sent delegates to the Constitutional Convention of 1787 at Philadelphia, but the state convention, at Hillsboro, called to ratify the constitution for North Carolina, did not meet until July 21, 1788, when ten states had already ratified. The document was strongly opposed because it contained no bill of rights and on the ground that it would provide for such a strong central government that the state governments would ultimately be sacrificed. At the conclusion of the debate the convention declared itself unwilling to ratify the constitution until a bill of rights had been added and it had been amended in several other particulars so as to guarantee certain powers to the states. But a second convention met at Fayetteville in Nov. 1789 and the constitution was speedily ratified (Nov. 21).

In 1789 also the University of North Carolina was chartered by the state legislature (opened to students in 1795) and the state ceded its western lands (Tennessee) to the United States. In 1792 a permanent capital was located at Raleigh and a capitol building was completed in 1794. The first banks were established in 1804 at New Bern and Wilmington. Superior courts were provided for each county in 1806 and a supreme court was created about the same time, though district judges for it were not provided until 1818. In the second war with Great Britain (1812–15), North Carolina's quota of 7,000 soldiers served on the southern frontier and along the Canadian border.

East-West Struggle.—The period from 1789 to 1835 was marked by a contest between the dominant eastern and the western counties. The west urged that equal county representation in the legislature be replaced by representation based on population. This was stubbornly resisted, and the west assumed a threatening attitude as the east opposed its projects for internal improvements for which the west had greater need. Finally in Jan. 1835 the legislature passed a bill for submitting to popular vote the question of calling a constitutional convention. In the election that followed in April, every eastern county gave a majority against the convention, but the west voted strongly for it and carried the election. In the convention, the east made some concessions, such as the popular election of the governor, the disfranchisement of free Negroes, the abolition of borough representation in the legislature, the choosing of state senators from districts according to public taxes, and the apportioning of members of the lower house (commoners) to counties according to population based on the federal ratio. The electorate gave its approval to the revision, and with this the agitation over representation ceased.

Whigs and Democrats.—The period 1835–60 was an age of progress in the state. After the constitutional reforms of 1835 broke the political dominance of the east, the new progressive Whig party controlled the state government from 1836 to 1850 and adopted the program of public education and internal improvements that had been proposed by state senator Archibald D. Murphey, pioneer advocate of public education, 20 years earlier. The Democratic party, generally dominated by the planter class, grew weary of successive defeats because of its negative program of opposition to Whig policies. It captured control of the state in 1850 because of its able young leaders (notably W. W. Holden and David S. Reid), its advocacy of free suffrage (abolition of 50-ac. requirement to vote for state senators), and the weakening of the Whig party as a result of the slavery controversy and the failure of the Whigs to press forward with the progressive program they had launched.

The Democratic party controlled the state from 1850 to 1862. Once in power it gradually adopted and extended the progressive program inaugurated by the Whigs. In the generation before 1860 the state government completed a new capitol in 1840 (the first one had burned in 1831), gave millions of dollars of aid for building of plank roads and a 900-mi. network of railroads, established (1839–40) and provided the major financial support for a state system of free public elementary schools for white children, established institutions for the care of the blind, deaf and insane, expanded the state system of taxation and made some liberal changes in the criminal law and in the legal status of women. The state university grew rapidly; many private academies were founded as well as colleges for women; and the leading denominations established colleges for men. Newspapers increased in numbers and circulation, and there was a beginning of indigenous authorship. Bright-leaf tobacco was developed, and there were many improvements in farming methods and increases in crop production (particularly cotton and tobacco). There was also a significant beginning of manufactures, notably cotton textiles. This age of progress and prosperity was brought to an end by the Civil War.

Civil War and Reconstruction.—The fundamental points of difference between North Carolina and South Carolina were exemplified in the controversy over slavery. South Carolina led the extreme radical element in the south and was the first state to secede (Dec. 1860). North Carolina held back, worked for a compromise, sent delegates to the Washington peace convention in Feb. 1861 and did not secede until May 20, 1861, after President Lincoln's call for troops to preserve the union. Entering the war reluctantly, the state furnished troops in excess of its voting population and of its relative population in the Confederate states. While making its full contribution of men, money and supplies to the Confederacy, the state, under the political control of the Conservatives after 1862 with Zebulon B. Vance as governor, sharply criticized the policies of the Jefferson Davis administration, contending that the Confederacy was encroaching upon the prerogatives of the states. The northeastern part of the state was captured by Federal troops in 1862 and held throughout the war. The battles of Ft. Hatteras, Plymouth, Ft. Fisher (the "Gibraltar of America") and Bentonville, Sherman's invasion in March 1865 and Johnston's surrender to Sherman near Durham on April 26, 1865, were the most notable events of the war in North Carolina. Wilmington remained the most important blockade-running port in the Confederacy until the fall of Ft. Fisher in Jan. 1865. About 40,000 North Carolina soldiers died in battle and from disease. The war had bled North Carolina white and left it with a depressing heritage of defeat.

Reconstruction was a difficult experience in North Carolina as in other southern states. In 1865 Pres. Andrew Johnson appointed W. W. Holden provisional governor until an election could be held. The convention of 1865 repealed the ordinance of secession, declared slavery abolished, repudiated the state war debt and scheduled elections for the establishment of a constitutional state government. Jonathan Worth, who was elected governor, was an honest and capable official, but the government established shortly thereafter in accordance with the views of congress was corrupt, inefficient and tyrannical. Carpetbaggers, Negroes and native whites known as scalawags were in control of affairs, while many people of wealth, refinement and education were disfranchised. The Republican party, organized in the state in 1867, took the lead in writing and adopting the constitution of 1868—a very liberal document—and captured control of the state government. Gov. W. W. Holden (elected 1868) was so unpopular and tyrannical that he was impeached, convicted and removed from office by the legislature in 1871. Under his successor, Tod R.

Caldwell, there was some improvement in the condition of affairs, and in 1875 a constitutional convention at Raleigh, with the Democrats slightly in the majority, amended the constitution, their work being ratified by popular vote at the state election later in the year. The native white element completely regained possession of the state with the reelection of Zebulon B. Vance as governor in 1876.

Late 19th Century.—For the next 20 years the Democratic party gave the state respectable, cheap government and kept the Negro from office and political influence; but under control of the conservative element, sometimes known as Bourbon Democrats, it neglected the needs of the great mass of farmers, catered to railroads and other business interests and sought to perpetuate itself in power by appeals to party loyalty and race prejudice rather than by meeting the social, educational and political needs of the state. Cotton, tobacco and furniture manufactures grew rapidly after 1880. Business prospered but agriculture was in a sad plight, as it was throughout the nation generally. Finally, the organized farmers of the state formed the Populist (People's) party, which in 1894 fused with the Republicans and carried the state; two years later, Daniel Russell, a Republican, was elected governor. The race question dominated the elections of 1898 and 1900, when the Democrats came again into power; and in 1900 a constitutional amendment (the literacy test and the so-called "grandfather clause") virtually disfranchising the Negro was adopted.

20th Century.—In the midst of this period came World War I, in which the state contributed over 86.000 persons to the armed services and $160.000.000 in bond purchases. A decade of significant highway, educational and other economic and social developments followed, being succeeded in turn by the depression of the 1930s, which brought widespread hardship and severe curtailment of education and other public services. The state government extended relief to the counties by assuming substantially the full cost of highways in 1931 and of public schools in 1933. By 1940 the state was beginning to enjoy another period of progress. Meanwhile, state-wide prohibition, in effect since 1908, was superseded in 1933 by a system of state-supervised county liquor stores.

In the 1940s the national defense program and World War II had important effects on North Carolina. Some of the country's largest military installations were located in the state, among them Ft. Bragg and Camps Lejeune, Butner, Davis, Mackall, and Cherry Point. More than 362.000 North Carolinians served in the armed forces and more than 7,000 lost their lives. Residents of the state subscribed over $1.800.000.000 in various bond drives. Almost $2.000.000.000 was spent in the state by the armed forces for manufactured war supplies, not including subcontracted materials, and North Carolina delivered more textile goods to the army than did any other state.

The state established a pension and retirement system for teachers and other state employees in the 1940s, provided a nine months' term for public schools and launched a vast medical care program, providing for a four-year medical school and hospital at the state university and hospitals throughout the state. Legislative appropriations were made to the North Carolina Art society and to the North Carolina Symphony society, the first instances of state financial aid to art and music. In 1959 the State Art museum at Raleigh had the most outstanding art collection in the south. In 1949 the voters of the state approved a bond issue of $200.000.000 for secondary road construction. Bond issues to the extent of $75,000,000 for construction of public school buildings were approved by the voters in 1949 and 1953.

Rapid industrialization, accompanied by urbanization, made manufacturing the chief source of the state's wealth and gave it pre-eminence in the nation in tobacco, cotton textiles and wooden furniture. Industrial expansion and diversification after 1950 were almost phenomenal. In national politics the state went Republican for the first time since Reconstruction when it voted for Herbert Hoover in 1928, but in 1932 the state returned to the ranks of the Democratic "solid south."

Among the most significant later developments in the state were the creation in 1956 of the state board of higher education; the reorganization of the state government by the creation of a department of administration; the revision of the corporate tax structure; the creation of the Research Triangle (University of North Carolina at Chapel Hill, Duke university in Durham and North Carolina State college at Raleigh) and the development of the Research park; and the adoption of the Pearsall plan to cope with the problem of desegregation in the public schools.

GOVERNMENT

North Carolina has been governed under the charters of 1663 and 1665 (1663–1729), under commissions and instructions from the crown (1729–76) and under the constitutions of 1776 and 1868, with numerous amendments. The present constitution, as amended, prescribes that no convention of the people of the state may be called by the legislature unless by the concurrence of two-thirds of all the members of each house, followed by an affirmative vote of a majority of the electors voting on the question; and that an amendment to the constitution may be adopted also by a three-fifths vote of each house, followed by an affirmative vote of the majority of electors voting on the question. The suffrage provisions containing the famous "grandfather clause" (in art. vi, sec. 4) were adopted in the form of a constitutional amendment, ratified in 1900, and in effect July 1, 1902. This amendment required that any applicant for registration must be able to read and write any section of the constitution; the grandfather clause, however, provided that no person who was entitled to vote on or before Jan. 1, 1867, or his lineal descendant, should be denied registration by reason of his failure to possess the educational qualifications, provided that he registered prior to Dec. 1, 1908. In effect, the amendment disfranchised Negroes. In June 1959 the supreme court of the United States upheld this literacy test.

Executive.—The constitution provides for an executive department consisting of a governor (not eligible for immediate re-election), lieutenant governor, secretary of state, treasurer, auditor, superintendent of public instruction, attorney general, commissioner of agriculture, commissioner of labour and commissioner of insurance, all elected by popular vote for terms of four years. An ex officio council of state is adviser to the governor. A utilities commission of three members, a commissioner of revenue, a highway and public works commissioner, a board of education, a board of higher education and other boards and commissioners are appointed by the governor. From 1776 to the constitutional revision of 1835, the governor was elected by the legislature for a one-year term; from 1835 to 1868 he was chosen by the voters for a two-year term; after 1868 he was chosen for a four-year term. The North Carolina governor has no veto power, the only instance of this kind in the nation. Yet the governor exercises vast power by control of appointments and by virtual control of state expenditures, as head of the budget bureau.

Legislature.—The general assembly comprises a 50-member senate and a 120-member house of representatives. A constitutional amendment in 1962 required the speaker of the house to reapportion the house after each federal census if the legislature fails to do so. The legislature in special session reapportioned both houses in 1966: house members are elected from 49 districts; senate members from 33 districts. Sessions of the general assembly are held biennially, beginning on the first Wednesday in February of the odd-numbered years. It usually remains in session from 60 to 90 days.

Judiciary.—The voters approved a constitutional amendment in 1962 to reorganize the state's judiciary into a general court of justice with appellate, superior and district court divisions and with an administrative office of the courts. The amendment required some 1.400 recorder-type and justice-of-the-peace courts to be replaced by Jan. 1, 1971, with a system of district courts, at least one per county, and with magistrates appointed by judges of the superior court replacing justices of the peace.

Local Government.—The governing body in each of the state's 100 counties is the board of county commissioners—either three or five—elected by popular vote for two-year terms. Other important elective county officials are the sheriff, clerk of superior court, register of deeds, treasurer, coroner and board of education. There are many appointive offices, among the most important being

a superintendent of schools and a superintendent of public welfare. Most of the revenues for county government are derived from taxes on real and personal property.

The three forms of city government in the state are: (1) mayor and council, (2) commission, and (3) city manager. The latter system is the most prevalent among the larger towns and cities.

Finances.—North Carolina is one of the few states in the Union that has no state tax on real property; this source of revenue was turned over to local governments in the 1920s. State revenue is derived chiefly from a general 3% sales tax, individual income taxes, corporate income taxes, motor fuel taxes and licence taxes. Major state expenditures, in order, are for public schools and institutions of higher learning, roads and highways, and health, welfare and safety.

POPULATION

The population of North Carolina in 1790 was 393,761; in 1830 it was 737,987; in 1870, 1,071,361; in 1910, 2,206,287; in 1940, 3,571,623; in 1950, 4,061,929; and in 1960, 4,556,155. This last figure represented an increase of 27.6% over the population in 1940 and of 12.2% over 1950.

The population per square mile in 1960 was 86.4, as compared with 77.1 in 1950, and with 49.6 for the U.S. in 1960.

*Populations are reported as constituted at date of each census. †Winston city and Salem town were consolidated under the name of Winston-Salem in 1913.

Note: Dash indicates place did not exist during reported census, or data not available.

Of the 1960 population, 1,801,921, or 39.5%, lived in [illegible] rated places of 2,500 or more, as compared with 33.7% in [illegible]. The state has six standard metropolitan statistical areas. [illegible] are Asheville, Charlotte (enlarged in 1963), Durham, Gr[illegible] High Point, Raleigh and Winston-Salem. These areas [illegible] in 1963) had a total 1960 population of 1,163,880.

The number of occupied dwelling units (or households) in 1960 was 1,204,715. The average population per household had declined from 4.0 in 1950 to 3.7 in 1960.

The population of the state was distributed by colour and nativity in 1960 as follows: 74.2% native white; 0.4% foreign-born white; and 25.4% nonwhite, nearly all Negro. There were 98.2 males per 100 females in the white population, and 94 [illegible] the Negro population; 6.8% of the population was 65 years and over; and 56.3% of the population 14 years old and over was in the labour force. Of the total number of employed, 12.8% were engaged in agriculture, 6% in construction, 31.7% in manufacturing and 21.6% in transportation and trade.

Most of the foreign-born white population of North Carolina is of English, Greek or German stock. The population of the state contains less than 1% of foreign-born persons.

EDUCATION

Public Schools.—The public-school system of North Carolina made remarkable and well-rounded progress after 1900. The total school expenditures between 1901 and 1929 increased from $[illegible] per capita of enrollment to $42.53. As a result of the depression public school expenditures dropped, but they rose rapidly in the decades during and after World War II. School attendance is compulsory between the ages of 7 and 16 inclusive. The length of school term and salary scale for white and Negro teachers are identical; in fact, the average Negro teacher's salary is [illegible] cause a larger percentage of Negro teachers hold class A certificates. From 1917, with the aid of federal funds, the state supported vocational education, particularly agriculture and home economics, in the public schools.

In the years following the supreme court ruling concerning racial segregation in the public schools (1954), some desegregation occurred under the pupil assignment law of 1956. Under the Pearsall plan the state constitution was amended in 1956 to permit state and local funds to be spent for private school [illegible] grants for children whose parents object to their attending [illegible] grated schools, and to allow local school units to close [illegible] schools if conditions should become "intolerable." Local school boards in many cities and counties admitted Negro pupils to schools that formerly were all white.

Higher Education.—There are about 40 senior (four years or more) colleges and universities in North Carolina, one-third [illegible] supported, the other two-thirds private or church-related. [illegible] The state also has a number of junior colleges, some of which [illegible] community colleges receiving local and state support, the other private or church-related institutions.

University of North Carolina.—Chief among the state institutions of higher learning is the University of North Carolina at Chapel Hill, chartered in 1789 and opened in 1795, one of the oldest state universities in the country and the first [illegible] operation in the south. Other branches of the consolidated university are North Carolina State of the University of North Carolina at Raleigh (founded 1887) and the University of North Carolina at Greensboro (1891). By 1860 the University [illegible] Carolina had become the largest university in the south [illegible] the best. It remained open during the Civil War though [illegible] dent body was very small, but, unable to weather the Reconstruction period, it was closed from 1870 to 1875. It struggled [illegible] the latter part of the 19th century and had a vigorous growth [illegible] World War I. In 1931 the consolidated university, comprising the three institutions, came into being. The university's colleges and schools at Chapel Hill include arts and sciences [illegible] gional planning, library science, social work, law, medicine, dentistry, nursing, pharmacy and public health. Its library [illegible] more than 1,000,000 volumes. North Carolina State of the [illegible]

[illegible]y of North Carolina at Raleigh includes schools of agricul[illegible], design, education, engineering, forestry and textiles. The [illegible]sity of North Carolina at Greensboro (formerly Woman's [illegible]) has schools of liberal arts, education, home economics and [illegible], and commercial and nursing education departments.

[illegible] State Institutions.—Other state-supported colleges are [illegible] Carolina college (1907) at Greenville, Western Carolina col[illegible] (1889) at Cullowhee and the Appalachian State Teachers [illegible] (1903) at Boone. State-supported Negro institutions in[illegible] the Agricultural and Technical college of North Carolina [illegible]) at Greensboro, the Winston-Salem Teachers college [illegible]), the North Carolina College at Durham (1910) and state [illegible]chers' colleges at Fayetteville (1877) and Elizabeth City (1891). A school for the Lumbee Indians of Robeson county is [illegible]ed at Pembroke. In 1963 three public community junior [illegible] Asheville-Biltmore, Charlotte and Wilmington—were [illegible]sformed into senior colleges, and legal provision was made for the creation of several more community colleges.

Private Institutions.—Among the nonstate-supported institu[illegible]s of higher education Duke university, formerly Trinity col[illegible] (Methodist), at Durham, is the greatest. It received from [illegible]s B. Duke the sum of $6,000,000 for building and an endow[illegible] fund estimated to be from $80,000,000 to $100,000,000, one [illegible] the largest foundations for education and hospitalization in [illegible] world (*see* DURHAM). Well-known church-related colleges [illegible] Wake Forest college (Baptist; 1833) at Winston-Salem; Da[illegible]n college (Presbyterian; 1837) at Davidson; Greensboro col[illegible] (Methodist; 1838) at Greensboro; Lenoir Rhyne college [illegible]an, 1891) at Hickory; Catawba college (Reformed; 1851) [illegible]ry; Meredith college for women (Baptist; 1891) at Ra[illegible] Elon college (Christian; 1889) at Elon; High Point college [illegible]dist; 1924) at High Point; Salem college for women [illegible]an; 1772) at Winston-Salem; Belmont Abbey college [illegible] Catholic; 1878) at Belmont; Guilford college (Quaker; [illegible]) at Guilford College; Atlantic Christian college (Disciples [illegible]hrist; 1902) at Wilson; Methodist college (1960) at Fayette[illegible]; North Carolina Wesleyan college (Methodist, 1961) at [illegible]ky Mount; and St. Andrew's college (Presbyterian, 1961) at [illegible]burg. Institutions originally established for Negroes in[illegible] Shaw university (Baptist, 1865) at Raleigh, Johnson C. [illegible] university (United Presbyterian; 1867) at Charlotte; [illegible]stone college (Methodist; 1879) at Salisbury; St. Augus[illegible] college (Episcopal; 1867) at Raleigh; and Bennett college [illegible]men (Methodist; 1873) at Greensboro.

HEALTH AND WELFARE

The chief state-supported institutions in 1960 consisted of hos[illegible] the white insane at Raleigh, Morganton and Butner and [illegible]tal for Negro insane at Goldsboro; the Caswell Training [illegible] for delinquents at Kinston, the North Carolina Orthopedic [illegible] for crippled children at Gastonia, the North Carolina hos[illegible] the treatment of spastic children at Durham, sanatoriums [illegible] treatment of tuberculosis at Black Mountain, McCain and [illegible]; the Stonewall Jackson Training school for delinquent [illegible] boys at Concord; the Eastern Carolina Industrial Training [illegible] for delinquent white boys at Rocky Mount, the Morrison [illegible] school for delinquent Negro boys at Hoffman, the train[illegible] school for Negro girls at Rocky Mount; the North Carolina [illegible] Home and Industrial School for Girls and Women at [illegible]and; and the Central prison at Raleigh.

[illegible] state has a very effective public health program headed by [illegible] board of health, established in 1877. All of the state's [illegible]ties have local health departments. North Carolina was [illegible] state to pass a law (1959) making poliomyelitis vaccina[illegible]pulsory.

THE ECONOMY

Agriculture.—North Carolina is a state of small farms, the [illegible] size being about 80 ac.; Texas is the only state having a [illegible]ber of farms. The leading crops are tobacco, corn, cot[illegible], hay and potatoes; and a great variety of other crops, [illegible] and vegetables is grown. North Carolina produces about two-fifths of the U.S. tobacco crop [illegible] tobacco used [illegible] tobacco [illegible]. The annual [illegible] from tobacco [illegible] to more than $[illegible] [illegible] in descending order were tobacco, [illegible] cotton lint, dairy products, eggs, hogs and forest products. North Carolina agriculture is being diversified rapidly; by the early 1960s livestock accounted for [illegible] of farm income as compared with about 16% in 1939.

In 1900 North Carolina was seventh among the southern states in the value of all farm crops. After 1920 it usually ranked 2nd in the south and from 5th to 13th in the nation. Nearly all farms are electrified. The state leads the nation in the number of 4-H club members.

The percentage of farms operated by tenants dropped from 44% in 1940 to 30% by the 1960s. Nearly 60% of Negro farmers are tenants, as compared with about 20% of white farmers.

Lumbering.—Woods and forests cover more than one-half the area of North Carolina, the total amount of standing saw timber approximating 50,000,000,000 bd.ft. Of this timber, about 40% is pine and other softwoods; the remainder hardwood. On rich forest resources are based the state's major paper, furniture and pulp products industries, which collectively rank third, after textile and tobacco manufactures. The annual pulpwood cut is approximately 1,000,000 cords, while the lumber yield rose from 544,000,000 bd.ft. in 1889 to 1,994,000,000 bd.ft. by 1950, in the latter year representing about 5% of the national total. More than two-thirds of the state's counties co-operate with the state division of forestry, and in the 1960s more than 16,000,000 ac. were receiving protection.

Fisheries.—In the sounds along the coast, in the lower courses of the rivers that flow into them and along the outer shores fishing is an important industry. The total value of the North Carolina fisheries runs to about $12,000,000 a year, the most important items being food fish, shrimps, menhaden and oysters. Chief oyster and crab fisheries are located in Pamlico sound, creeks and inlets; shrimp fisheries are concentrated in Pamlico sound, rivers and creeks, and offshore in the Atlantic.

Minerals.—More than 300 different rocks and minerals are found in North Carolina, about 75 of them commercially valuable. From 1800 to 1848 North Carolina was the leading gold producing state, having mined approximately $60,000,000 worth of the precious metal. After 1900 the state normally ranked from 36th to 39th among the states in the total value of its annual mineral production. It is noted chiefly for its nonmetallic minerals. Mineral products (in descending order, according to value) include building stone (by far the most important), sand and gravel, feldspar, mica, clays, talc and pyrophyllite and tungsten. The state usually ranks first in the nation in the production of feldspar and mica, second or third in talc, and vermiculite and tungsten.

Manufactures.—The value of manufactures in North Carolina after World War II rose to exceed that of farm products. North Carolina is the leading industrial state of the south and one of the dozen foremost industrial states of the nation. In all such indexes as number of plants, labour force, total salaries and wages paid, value of raw materials used, total value of output and total value added by manufacture, North Carolina ranks from 10th to 14th among the states. Its leading manufactures (listed in descending order, by value of output) are textiles, tobacco, food products, furniture, chemicals, lumber, electrical machinery and pulp and paper. [illegible] North Carolina leads all other states.

The textile [illegible] employed in manufacturing. Gaston, Mecklenburg and Guilford counties have been the leaders in textile manufacture, Gaston county having more cotton mills than any other county in the United States. Hosiery mills have been concentrated in the Piedmont, with Winston-Salem, Asheboro, Burlington and Durham being [illegible] W[illegible] Greensboro. High Point has been the [illegible] centre [illegible]

manufacture, but other important centres are Thomasville, Lexington, Lenoir, Statesville, Newton-Conover, Hickory, Mount Airy, Sanford and a number of other towns.

Transportation and Communication.—Railway building was begun in North Carolina in the 1830s, and the state's first two railroads, the Wilmington and Weldon and the Raleigh and Gaston, were completed in 1840. By 1860 nearly 900 mi. had been built with state aid, the most important road being the North Carolina railroad, extending from Goldsboro to Charlotte; this road is still owned by the state, though leased to the Southern railway. Great expansion, accompanied by consolidation of many small lines into larger systems, occurred between 1880 and 1900. Railway mileage in the second half of the 20th century, however, was slowly declining.

After 1920 great progress was made in highway construction and in the development of a state system of highways. By the early 1960s the state was maintaining a system of more than 70,000 mi. and registered motor vehicles numbered almost 2,000,000 annually. There were several regularly scheduled airlines and more than 100 airports and airfields.

In 1911 the Inland or Intracoastal waterway, built with federal funds, was completed between the Neuse river and Morehead City; the whole project was completed in 1936. The state has two ports of entry for ocean-going vessels: Wilmington and Morehead City.

The state has about 180 radio stations and 12 television stations; nearly 50 daily newspapers and about 150 other newspapers.

Current statistics on production, employment, industry, etc., may be obtained from the pertinent state departments; the principal figures are summarized annually in the *Britannica Book of the Year*, American edition. (A. R. N.; H. T. L.)

NORTH CAROLINA, UNIVERSITY OF, one of the oldest state universities in the United States, was chartered in 1789 and began instruction in 1795 at Chapel Hill, N.C. *See* NORTH CAROLINA: *Education*.

NORTH-CENTRAL PROVINCE, CEYLON, the N.C.P." to those who know it well, covers 4,009 sq.mi. of undulating country lying for the most part between 50 and 500 ft. above sea level (the province has no coast). There rises from the lowland a series of ridges (like those running from the central highlands of Ceylon to Trincomalee), and of isolated hills, the highest of which is Ritigala (2,514 ft.). Pop. (1960 est.) 308,000, mainly Sinhalese. Almost the whole province is floored by ancient crystalline rocks, the ridges being made of quartzites. East of these ridges the land drains to the Mahaveli Ganga, which is followed by a belt of alluvium; to the west of them drainage is mainly to the northwest.

The province falls in Ceylon's lowland dry zone, with its marked alternation of heavy rains during the northeast monsoon and severe drought during the southwest (*see* CEYLON: *Physical Geography*). Except to the southwest the N.C.P. is almost completely ringed by sparsely inhabited country, much of it still covered with the mixed evergreen and deciduous forest appropriate to the local climatic regime. A rather degraded version of the same forest fills the wasteland between the villages of the rest of the province, while on the east there are patches of poor grassland (*damana*) like that of the Eastern province. Elephant and other wild animals are to be found in the forests and *damanas*. The Wilpattu National park lies across the boundary with the North-Western province.

The modern N.C.P. is almost coterminous with the Rajarata ("king's country") of the ancient Sinhalese and was, in fact, the heartland of their civilization. (*See* CEYLON: *History*.) There they built and adorned their two great capitals, Anuradhapura and Polonnaruwa (*qq.v.*), whose splendid ruins have been rescued from the jungle and carefully preserved. These cities and other settlements were supplied with water for their rice fields and for their other needs by great and skilfully constructed irrigation works (notably the tanks near Minneriya, Polonnaruwa and Anuradhapura), many of which have now been restored to working order. All over the province, too, are many scattered sites of great archaeological and aesthetic interest.

The chief towns are Anuradhapura, capital of the province and of a district (pop. [1953] 18,390), and Polonnaruwa, also a district capital, both growing rapidly. Since the breakdown of the ancient civilization the N.C.P. has been the scene of struggling villages whose inhabitants grow rice irrigated by small tanks and practise shifting cultivation in the surrounding forest. Many such villages remain, now freed from malaria, but they are losing their isolation and, with it, some of their distinctiveness and charm. It is the restoration of the great irrigation works that now attracts people to the N.C.P. and leads them to a new landscape, dominated by wide acres of rice. There is a fairly good road network and a main line of railway. (B. H. F.)

NORTHCLIFFE, ALFRED CHARLES WILLIAM HARMSWORTH, 1ST VISCOUNT (1865–1922), the most successful newspaper publisher in the history of the British press and the creator of popular modern journalism, was born at

Chapelizod, Dublin, July 15, 1865, the eldest of a family of 14. His father, Alfred Harmsworth (1837–1889), was an impecunious schoolmaster who after the birth of his second child was persuaded by his wife's social ambitions to give up a teaching post in Dublin and move to London to read for the bar, becoming in due course an unsuccessful barrister of convivial temperament whose large family was brought up in genteel but often acute poverty interrupted by bouts of Bohemian extravagance. His mother, who died in 1925 aged 87, was the guiding force in the family, exercising over her first-born (the description of himself with which he signed his daily letters to her) an emotional dominance which made other intimate personal relations difficult for him.

Of the seven sons, the three eldest all became members of the house of lords: Alfred, Harold, 1st Viscount Rothermere (*q.v.*), and Cecil Bisshopp (1869–1948), 1st Baron Harmsworth of Egham. The fourth, Robert Leicester (1870–1937), was made a baronet.

The Harmsworths moved to London in 1867, and after an unhappy interlude at Stamford grammar school, Alfred was educated until he was 16 at a struggling private school owned by the father of A. A. Milne, the writer. He showed considerable talent as founder and editor of the school magazine but no gift for sustained study. After several attempts to "get rich quick" by inventing and selling a silk hat reviver and an all-purpose pill, and after having a position with the amiable son of a peer as secretary-companion on a continental tour, he embarked on free-lance journalism as a contributor to popular papers such as *Comic Life*, *Scraps*, *Young Folk Tales* and *Youth*, of which last he became editor at a salary of £2 a week. In 1885, after a temporary breakdown in health, he went to Coventry as editor of *Bicycling News*, owned by the firm of Iliffe, at £2 10*s*. a week, and began to contribute to *Tit-Bits*, the phenomenally successful popular weekly of informative scraps for the new reading public created by the Education act of 1870. The success of *Tit-Bits*, which has some claim to be regarded as the initiator of the revolution in popular journalism in which Northcliffe himself played such a leading part, fired him with the ambition to start a similar paper of his own to be called *Answers to Correspondents*. He tried to interest Iliffe's in the scheme. They turned it down but promised to print it for him on credit for a few weeks if he could get someone to back him, and in 1887 he left to seek his fortune in London. There, with a few hundreds put up by the son of a Dublin friend of his mother's, he began to publish cheap booklets (most of them written by himself) on careers, a cure for biliousness and any other subject likely to attract popular interest. He had little financial success until an introduction to an ex-army officer with a rich wife enabled him to raise enough money to take advantage of Iliffe's offer in 1888. (This was soon after his marriage to Mary Elizabeth, daughter of Robert Milner, a West Indian merchant.)

Answers to Correspondents, soon shortened to *Answers*, was the foundation of Northcliffe's career. It was not, however, an immediate success and was only saved when a simple puzzle brought to the office by an American visitor proved a hit. A competition offer of £1 a week for life for guessing the amount of gold coin in the Bank of England on a certain date established it in public favour. By this time Alfred had been joined by his brother Harold (who had been ordered by his mother to resign a safe job as a civil service clerk to help her first-born through the financial tangle which threatened his enterprises). The combination of Alfred's genius for sensing the public taste and Harold's financial ability and capacity for attracting advertising by exploitation of the idea of the net sales certificate proved irresistible. *Answers* was followed by a host of other cheap popular periodicals, chief among them *Comic Cuts* ("Amusing Without Being Vulgar") and *Forget-Me-Not*, for the new reading public of women. These formed the basis for what became in Amalgamated press (from 1959 Fleetway press) the biggest periodical publishing empire in the world.

But although Alfred Harmsworth enjoyed wealth his primary passion was journalism. In Aug. 1894 he seized the chance presented to him by an ambitious young journalist, Kennedy Jones, who had, with a friend, acquired an option on the nearly bankrupt *London Evening News*, bought the paper for £25,000 and launched into newspaper publication. The flair that had brought such results with cheap weekly magazines proved equally effective with newspapers. The character of the *Evening News* was changed overnight. Long news reports and long leading articles were banished, a column for women was started and a daily short story introduced. About £300,000 had previously been sunk in the paper without success, mostly by the Conservative party. Within a year Harmsworth had a circulation of 160,000 copies and was making a substantial profit. For the first time in his life he found himself cultivated as a political influence by men who would have taken no notice of the owner of *Comic Cuts*. He enjoyed the experience. He next conceived the idea of a chain of halfpenny morning papers in the provinces and made a start by buying up two papers in Glasgow and merging them into the *Glasgow Daily Record*. His touch with a Scottish public proved, however, less sure, and he decided to embark instead on the experiment of a popular national daily published in London. The *Daily Mail*, first published on May 4, 1896, was the result. It was a sensational success. Announced as "The penny newspaper for one halfpenny" and "The busy man's daily journal," it struck a new note that was exactly suited to the new reading public. "Explain, simplify, clarify," Harmsworth told his staff. All news stories, leaders and feature articles were kept short, and articles of interest to women, political and social gossip and a serial story were made regular features. Although news headlines remained, at first, modest in size, far more were used than in any previous paper. With its first issue the *Mail* established a world record in daily newspaper circulation and this lead it never lost while Northcliffe lived. He moved on to new triumphs. He bought the *Weekly Dispatch* when it was nearly bankrupt and turned it (as the *Sunday Dispatch*) into the biggest selling Sunday paper in the country, founded the *Daily Mirror* (1903), which, after a false start as "a paper for gentlewomen," found success in exploiting a wholly new market as a picture paper with a circulation rivaling that of the *Mail*, saved the *Observer* from extinction (1905) and in 1908 reached what he believed to be the pinnacle of his career by securing control of *The Times*.

Northcliffe (he was created a baronet in 1903 and raised to the peerage as Baron Northcliffe in 1905) was the most successful popular journalist of his own or any other day because he knew instinctively what the new, semieducated public wanted. He was one of them himself: he thought as they did, although at a level infinitely more charged with energy and imagination. He lacked the power of sustained thought or abstract judgment but he had a passionate curiosity about practical things, an insatiable appetite for facts and was genuinely excited by everything new. Lord Robert Cecil called the *Daily Mail* "A newspaper for office boys written by office boys," but Northcliffe knew that his readers were office boys on the way up: "Remember," he told his staff, "you are writing for people with £1,000 a year—or at any rate people who hope and think they'll be £1,000-a-year men tomorrow." Success lay, he believed, in flattering readers by letting them see "their own opinions and prejudices echoed in a newspaper," and since most of these opinions and prejudices were his own he found this easy. He was a popularizer of genius. As the element of megalomania in his character swelled with success he came to believe that the genius that had brought him immense circulation also gave him the right to speak for the nation. He believed in his power to sway public opinion by, in his own words, "telegraphing a message to millions with damnable retention," and he undoubtedly had great influence on the social habits of the new middle class. But although he came to believe that he controlled immense political power through his newspapers (an opinion confirmed by many around him) there is little evidence that his direct impact on public events was large. Thus, although he performed a valuable service by his exposure of the shell shortage in the early days of World War I, his attacks on Lord Kitchener, which led to the *Daily Mail's* being publicly burned on the stock exchange, probably delayed changes on which the cabinet had already decided. He tended to be used as a megaphone by men more politically adroit than himself. Thus, although he claimed to have brought about

the downfall of Asquith, he was unable to exercise any influence over the composition of the new administration and his final break with Lloyd George at the end of the war, when Lloyd George contemptuously rejected his demand to be consulted on the membership of the cabinet in return for his newspapers' support, had no perceptible effect on the results of the postwar election. He did valuable wartime service as head of the British war mission in the United States (June–November, 1917), for which he received a viscountcy, and (from Feb. 1918 until the end of the war) as director of propaganda in enemy countries, but failed to secure for himself the official place at the Versailles peace conference on which he had set his heart.

He wanted power. What he got was big business, setting in motion forces that changed the direction of much of the press away from its traditional informative and interpretative role to that of the commercial exploiter and entertainer of mass publics who had always to be given what would excite and amuse them. The financial reward was enormous, not only from sales but from the advertising revenue the great new circulations were able to attract, and Northcliffe spread some of this wealth in higher wages and better conditions for all who worked on newspapers. But he failed to achieve the power he craved because he lacked the ultimate quality of the great journalist, the patience to persuade. For this reason, although he brought *The Times* financial support at a time when it was crippled by losses, by dissension among minority shareholders and by an out-of-date 18th-century constitution, and transformed it from a 19th-century relic into a modern newspaper, *The Times* was, in a deeper sense, one of his failures. He tried to turn it into an instrument of personal policy, not seeing that to do so would be to destroy the very foundation of its authority. He was destroyed by the nature of his own success. Always unpredictable, he became the victim of a megalomania that destroyed the balance of his judgment and led him into extravagances of autocratic decision that made it difficult even for those who most admired him to work with him. He was persuaded to go on a prolonged world tour as a rest cure but a complete breakdown followed and on Aug. 14, 1922, he died in London.

(E. F.-Ws.)

NORTHCOTE, JAMES (1746–1831), English painter, known largely for his historical paintings, but also a portraitist of considerable skill, was born at Plymouth on Oct. 22, 1746. In 1773 he went to London and was admitted as a pupil into the studio and house of Reynolds, attending also the Academy schools. He was elected associate of the Academy in 1786 and full academician in the following spring. He died on July 13, 1831.

Northcote's output, especially of portraits, was prodigious; there are a number of examples in the National Portrait gallery, London. His sitters included many notable persons, among them Samuel Taylor Coleridge and John Ruskin. Northcote was one of the chief painters employed by John Boydell (*q.v.*) for his Shakespeare gallery, some of his works on this commission being "The Murder of the Young Princes in the Tower," "The Burial of the Young Princes" and "Prince Arthur and Hubert." Northcote wrote lives of Reynolds (1813) and of Titian (1830), whose lifelong admirer he was, and two series of *Fables*.

NORTH DAKOTA, the "Flickertail state," is one of the north central group of the United States lying in an area designated by the U.S. geological survey as the centre of the North American continent. It is bounded on the north by the Canadian provinces of Manitoba and Saskatchewan, on the east by Minnesota (from which it is separated by the Red river), on the south by South Dakota and on the west by Montana. Extending 341 mi. from east to west and 212 mi. from north to south, it has a total area of 70,665 sq.mi., of which 1,208 sq.mi. are water surface, and it ranks 17th among the states in size. The state capital is at Bismarck (*q.v.*). North Dakota entered the union in 1889, the 39th state in order of admission. The wild prairie rose is the state flower and the state tree is the American elm. The state bird is the western meadow lark. The name of the state is derived from *dakota*, a Sioux word meaning "allies." The nickname is that of the tiny Richardson's ground squirrel, or yellow gopher.

PHYSICAL GEOGRAPHY

Physical Features.—The land surface of North Dakota consists largely of rolling prairies and plains, slowly rising half a mile in altitude from east to west to form a series of three successive steps or plateaus. The eastern or lowest part is made up of the flat valley of the Red river, once the bed of Lake Agassiz, formed by a retreating glacier. The area varies in width from 40 mi. near the Canadian border to 10 mi. near the South Dakota line. On the western edge of the Red river valley the land rises sharply, marking the beginning of the central plateau, sometimes referred to as the drift plain or prairie. It varies in elevation from 1,650 ft. in the Pembina mountains to 1,350 ft. in the south where the hills rise again to become the Couteau des Prairies in Sargeant county in the southeast corner of the state. The drift prairie is a rolling fertile plain varying in width from 70 mi. in the south to more than 200 mi. along the Canadian border, broken by low ridges of hills, shallow coulees and numerous small lakes. Devils lake, the largest natural body of water in the state, and the Turtle mountains lie in the northern part.

Rising 300 to 400 ft. above the drift plain and cutting across the state diagonally in a northwest-southeast direction is the third area, the Missouri plateau. Between the escarpment and the Missouri river the plateau is known as the Couteau du Missouri and west of the river as the Missouri slope. The surface is irregular and rolling, dotted with old lake beds, some of which contain large deposits of sodium sulfate, valuable clays and large beds of lignite coal. The Missouri slope is the most unusual area of the state. In it are located the badlands of the Little Missouri river where a fantastic array of buttes and mesas characterize the landscape. Vividly exposed layers of bright coloured clay and scoria indicate that the various buttes were at one time connected. The highest point in the state is Black butte, 3,468 ft. above sea level. In the western part the Killdeer mountains rise about 700 ft. above the surrounding region.

Climate.—North Dakota has a continental climate with a wide range of temperature. The mercury often reaches 100° F. (about 38° C.) during the summer and falls at times to −30° F. (−34.4° C.) during the winter months. The average temperature for June, July and August is 65.7° F., and for December, January and February, 9.7° F. A relatively low humidity, averaging 68% makes the extremes less noticeable. The sections vary greatly in precipitation, ranging from 22 in. in the southeastern corner to about 14 in. in the southwestern portion. Most of the rainfall comes in the late spring and summer during the growing season. The state is subject to alternating wet and dry years, with crop yields ranging from very good to almost complete failures. Long severe winters are typical, with an average snowfall of 30 in. Blizzards are common on the drift plain and cyclonic action during the summer months produces much of the precipitation.

Soil.—The soils of the state may be roughly divided into three general types based on their origins: the lake-bottom soils in the east, the glacial soils in the central section and the residual soils of the western portion. Small areas of alluvial land are to be found along the Missouri, James and Sheyenne rivers. In the Red river valley the soils are of the rich black loam type, 20 to 30 ft. in depth, formed in lake beds from which the water long ago disappeared. The soil change from the lake-bed area to the glacial-drift types of the central region is abrupt. The drift left by the Wisconsin glacier plus a dense grass cover produced the soils of central North Dakota. The top layer is black or dark brown loam below which lies the glacial debris of sand, gravel and boulders that is exposed in places. Farther west the soil is thinner and lighter in colour. Boulders are common and often show through the earth surface; there also are outcroppings of sandstone and shale, indicating evidence of glaciation.

Vegetation.—Because of its semiarid climate North Dakota has only about 600 sq.mi. of wooded area. In the Red river valley, Turtle mountain and Devils lake regions, such trees as the [illegible] Juneberry, elder, green ash, poplar and cottonwood are common.

THE STATE CAPITOL AND OTHER SCENES IN NORTH DAKOTA

Top: The capitol building, Bismarck. The 19 story building was designed in 1932 by J. B. de Remer and W. F. Kurke, North Dakota architects

Bottom left: Blockhouse at Fort Abraham Lincoln State park. Gen. George Custer led his troops from this fort to the battle of Little Big Horn in 1876

Bottom right: Four Bears bridge, near the upper end of the Garrison reservoir, is known as the "bridge with 19 names." Because of jealousy between the Mandan and Hidatsa Indians, plaques were fixed at each end of the span bearing a list of names of rival tribal chieftains as associate titles of the bridge

chokecherry and wild plum trees, high-bush cranberries and wild grape bushes grow abundantly along the eastern streams. In the Missouri and Little Missouri regions are found the broadleaf cottonwood, willow, ash and elm, as well as bushes of the buffalo berry and the flowering currant. Of the Rocky mountain types of trees, some stunted yellow pine and red cedar are to be found in the badlands and on the buttes of the Little Missouri. The tall Indian and blue grasses of the east are replaced by grasses of medium height in the central area and by the shorter, grayish varieties of buffalo and grama grasses in the west. Wild flowers, the yellow violet, cornflower, blue and yellow flax, black-eyed Susan, yellow goldenrod, sunflower and wild prairie rose, grow in great profusion throughout the state.

Animal Life.—In early times large numbers of buffalo, elk, deer and antelope roamed the North Dakota area, providing a permanent source of food, clothing and shelter for the native Indian tribes. With the coming of the railroad and the final defeat of the Indians in the 1880s, large numbers of these animals were destroyed for their hides and for sport. Scattered remnants of the once great herds took refuge in the badlands where state laws saved them from annihilation. In the fur-trading period the most valuable animals were the beaver, mink, otter, fisher and marten and less-valuable pelts were obtained from the weasel, black-footed ferret, skunk, red fox and raccoon. Other animals sometimes killed for their skins included the black and grizzly bear, mountain lion or cougar and buffalo wolf. Trapping of fur-bearing animals is still an important activity in North Dakota and is often followed by farmers during the winter months. Small animals common in the state are the coyote, chipmunk, squirrel, ferret and the yellow gopher or flickertail.

Among the many songbirds in the state are the sparrow, oriole, blue jay, robin, black-billed cuckoo, blackbird and meadow lark. Many waterfowl nest in the state each year. The most important upland game bird is the pheasant and the town of Mott in Hettinger county, in the southwest corner of the state, is called the pheasant capital of the state. There are extensive migratory bird and animal refuges scattered throughout North Dakota. Perch, black and rock bass, pickerel, pike, sunfish and catfish are found in the larger lakes and rivers. Suckers and carp are also common.

State and National Parks.—The best-known park in North Dakota is the Theodore Roosevelt National Memorial park of 70,436 ac., lying in the scenic badlands of the Little Missouri river. The park is visited by more than 170,000 persons annually. The Fort Abraham Lincoln State park of 750 ac., located just west of Bismarck on the western bluffs of the Missouri river, contains the sites of two early military posts and a Mandan village. The Turtle River and Lake Metigoshe State parks and the International Peace garden, partly in the state and partly in Manitoba, are popular with tourists. The 15-room château of the French nobleman the marquis de Mores, built in 1883 at Medora where he attempted to set up a meat-packing establishment, was given to the state in 1936 with its original furnishings.

HISTORY

The first white men to visit North Dakota were members of an expedition from Ft. La Reine (Portage la Prairie, Man.) led by Pierre Gaultier de Varennes, sieur de la Vérendrye. They reached a Mandan earth-lodge village in 1738, possibly the Menoken site, 13 mi. E. of modern Bismarck.

Two sons of Vérendrye crossed the Missouri near Sanish in 1742 and explored the country to the southwest in an attempt to carry out their father's dream of establishing an overland trade route to the Pacific. After reaching the Bighorn mountains they abandoned their search and recrossed the Missouri at Old Crossing. After the English occupation of Canada in 1763 the Hudson's Bay company and the North West company, operating from Ft. Garry (Winnipeg), established trading posts on the Missouri at the mouth of the Knife river where they were found by the Lewis and Clark expedition that wintered at Ft. Mandan in 1804–05. The purchase of the Louisiana territory by the United States in 1803 and the success of the Lewis and Clark expedition made St. Louis a rendezvous for American fur traders who exploited the fur resources of the upper Missouri. The American Fur company built, among others, Ft. Clark in 1826 and Ft. Union in 1829. The War of 1812 put an end to British attempts to extend the Canadian frontiers southward. By the treaty of Paris of 1818 the international boundary was fixed at the 49th parallel as far west as the Rocky mountains.

The first white settlement in North Dakota was made by a band of settlers from Lord Selkirk's colony of Scottish Highlanders in Manitoba, who settled at Pembina in 1812. When Maj. Stephen H. Long explored the Red river valley in 1823, he reported the population as numbering 350. Ft. Snelling (St. Paul) was established in 1823, and a brisk trade between this fort and Ft. Garry soon developed along both sides of the Red river. Ft. Abercrombie was built in 1858 and Ft. Pembina in 1863, and these forts became the rendezvous for commercial and military operations in the northwest, as well as rallying points for settlers.

Between 1850 and 1870 there was considerable difficulty with the Dakota (*q.v.*) Indians, whose lands in Minnesota had been largely appropriated by the whites and whose buffalo herds on the Dakota prairies were fast being depleted. The Minnesota outbreak of 1862 was followed by campaigns which finally drove the hostile Dakotas to the badlands west of the Missouri (*see* MINNESOTA: *History*). All eastern North Dakota was then open for occupation, and the completion of the first railroad to the eastern border in 1871 inaugurated the settlement period in earnest. The following decade saw intensive development in the Red river valley, and by 1880 settlement was spreading into the drift plain, especially along the line of the Northern Pacific railway which in 1873 had reached the Missouri at Bismarck. West of the Missouri the country was made attractive by the extension of the Northern Pacific, while the completion of the Great Northern railway across the northern part of the state in 1887 opened that region to settlers.

The region forming North and South Dakota, which after 1861 had been known merely as Dakota territory, was divided in 1889 into a northern and southern half. A convention met in North Dakota in July and framed a constitution which was accepted by the people in an election held on Oct. 1. Pres. Benjamin Harrison declared the state's admission to the union simultaneously with South Dakota on Nov. 2, 1889. The population of North Dakota was then almost 175,000.

The period 1890–1915 was one of constant growth. Competing railway lines strove to forestall each other in tapping promising grain territory. Once there they did their best to bring settlers into the newly opened region by conducting land excursions. Nearly 18,000 immigrants annually made new homes in the state. Settlement of the drift plain was practically completed and homesteaders invaded the good land beyond the Missouri river. The inrush continued with little abatement until after World War I when, because of the general depression in agriculture, it practically ceased. The economic distress of North Dakota's farmers during the depression was greatly increased by severe drought and dust storms between 1929 and 1935. During World War II all agricultural production records were broken.

In politics North Dakota is normally Republican, but its farmers and other dissatisfied groups have shown a tendency to desert the party in times of agricultural distress and form separate factions that usually promised more direct and radical remedies. It was one of the states involved in the Populist movement of the 1890s. In 1915 a number of Republican party members who were dissatisfied with the method of marketing grain organized the Nonpartisan league with A. C. Townley, a Socialist, as the head of the organization. By 1918 the league had elected a governor and a majority in both houses of the legislature.

In 1920 the Nonpartisan league lost much of its prestige, and many people from all parties opposed its program. Forgetting party lines, leaders of this opposition group formed the Independent Voters association (I.V.A.), which was influential in government during the remainder of the decade. In 1932 the league again came into control with the election of William Langer (1886–1959) as governor. Removed from office in 1934 for allegedly seeking political contributions, Langer won an appeal from conviction and was re-elected governor in 1936.

To combat the league the Democratic party and conservative Republicans formed a coalition in 1938 and elected John Moses, a Democrat, governor. Langer, however, was elected to the U.S. senate as a Republican in 1940 and was re-elected three times, the last time as an independent. Conservative Republicans, attempting to develop a strong party in 1943, adopted the name Republican Organizing committee (R.O.C.) and elected Fred G. Aandahl governor for three terms. Aandahl was succeeded by Norman Brunsdale and John E. Davis, both Republicans. In 1960 the Democrats showed some signs of resurgence with the election of Quentin N. Burdick to the U.S. senate and of William L. Guy as governor.

In most presidential elections after 1900 the state voted for Republican candidates but it supported Democratic candidates Woodrow Wilson in 1912 and 1916, Franklin D. Roosevelt in 1932 and 1936, and Lyndon B. Johnson in 1964. The majority for Roosevelt in 1932, 71%, was matched only by that for Republican Dwight D. Eisenhower in 1952.

GOVERNMENT

The constitution of North Dakota provides for a government operating on the state, county, township and municipal levels. The voters of North Dakota in 1964 approved an amendment to the constitution increasing from two to four years the terms of the governor, lieutenant governor, secretary of state, auditor, treasurer, superintendent of public instruction, commissioner of agriculture and labour, commissioner of insurance and county superintendents of schools. The tax commissioner also serves four years; the three public service commissioners six years. The governor appoints other state officials and the members of numerous boards and commissions.

The legislative assembly consists of a house of representatives of 106 members elected for two-year terms and a senate of 53 members elected for staggered terms of four years.

The state judicial system consists of a supreme court of five members elected for ten years and six district courts with judges elected for six-year terms.

The county is an important administrative unit. Each of the 53 counties in the state elects county commissioners for four-year terms and a sheriff, auditor, register of deeds, treasurer and state's attorney for terms of two years.

The township acts as a local unit of government for the county. Municipal governments are of the commission and mayor-council types.

About 40% of state tax collections come from the retail sales tax, 20% from an income tax and the balance from taxes on cigarettes, beer, liquor, oleomargarine, motor vehicle registration, oil and gas production and from the use tax.

POPULATION

The population of the North Dakota area increased from 2,405 in 1870 to 577,056 in 1910 and to 680,845 in 1930. With the agricultural depression of the 1930s people began to leave the state in considerable numbers, and the population dropped to 641,935 in 1940 and to 619,636 in 1950. In 1960 the population of the state was 632,446. The population per square mile in 1960 was 8.9 as compared with 49.6 for the United States as a whole.

*North Dakota: Places of 5,000 or More Population (1960 census)**

Place	Population				
	1960	1950	1940	1920	1900
Total state	632,446	619,636	641,935	646,872	319,146
Bismarck	27,670	18,640	15,496	7,122	3,319

Williston	11,866	7,378	5,790	4,178	763

*Populations are reported as constituted at date of each census.

While the population is largely rural, the percentage of peopl living in areas considered urban increased from 16.6% in 193 to 35.2% in 1960. The state had one standard metropolitan sta tistical area, which is Fargo-Moorhead. This area had a tota population of 106,027 in 1960, 66,947 in North Dakota. In 196 12.0% of the population was 65 years old and over; and 36.5% o the population 14 years old and over was in the labour force.

Large numbers of immigrants moving into the state prior t World War I resulted in a large representation of foreign group among the more important of which were Norwegians, Russians Canadians and Germans. In 1960, 93.3% of the population of th state was native white and 4.7% was foreign-born white. Ther were 11,736 Indians in the state in 1960, largely from the Hidats (*q.v.*), Mandan, Arikara (*q.v.*), Chippewa (*see* OJIBWA) and Siou (*see* SIOUAN INDIANS) tribes.

EDUCATION

The state department of public instruction under an electe superintendent supervises elementary and secondary schools Schools are supported largely by local taxes, although seven twelfths of the state sales tax is distributed to the various district through an equalization fund. A revolving fund of $5,000,000 wa provided by the state in 1923 to aid needy school districts in th construction of buildings. The money is loaned to the district and is repayable in 20 years with interest.

North Dakota has nine state institutions of higher learning under a seven-member board of higher education appointed by th governor. The system was established by constitutional amend ment in 1939. The University of North Dakota at Grand Forks founded in 1883 under the Territorial act, includes colleges of science, literature and arts, education, engineering, business and public administration, and nursing, schools of law and medicine a graduate school and the university college.

Also under the board of higher education are North Dak State university, formerly North Dakota Agricultural college (es tablished 1890), at Fargo, which includes six colleges, the state agricultural experiment station and eight branch stations located throughout the state; state teachers' colleges at Ellendale (1889 Mayville (1889), Valley City (1889), Minot (1913) and Dick son (1916); and two junior colleges, the North Dakota School Forestry at Bottineau (1906) and the North Dakota State Schoo of Science at Wahpeton (1903).

Jamestown college, a private coeducational institution affiliated with the Presbyterian Church, was founded in 1884 at Jamestown.

HEALTH AND WELFARE

The state correctional and charitable institutions include a state hospital for mental patients at Jamestown, a school for the dea at Devils Lake, an institution for the feeble-minded at Grafton a state training school at Mandan, a school for the blind at Gran Forks, a penitentiary near Bismarck and a tuberculosis sanator at San Haven near Dunseith. These institutions are under th general control of a state board of administration; the work o the state agencies for the care of children, the aged and the phys cally handicapped is co-ordinated through the state welfare board A home for soldiers at Lisbon is under a special board.

THE ECONOMY

Living Conditions.—A large percentage of the people o North Dakota live on farms or in small villages. The standard of living is relatively high as indicated by retail sales, home owne ship, wealth and property distribution. More than 45% of th farm homes have telephones and 88% have electricity. On family in four has its own power plant. More than 60% hav refrigerators or deep freezes. More than 90% of the farmers own tractors and 80% have automobiles.

The number of nonagricultural workers rose substantially afte World War II, the largest increases occurring in mining constru tion, manufacture of nondurable goods and in general trade an finance. Hourly wage increases in manufacturing were sligh below national levels. Because of the lack of industrialization th labour supply considerably exceeded the demand. In 1947 th

state legislature passed a "right to work law" that was amended in 1949.

Agriculture.—North Dakota has had an agricultural economy since statehood. The trend in the second half of the 20th century has been toward larger farms. In the 1960s it was estimated that there were about 50,000 farms in the state, with an average size of about 800 ac. Spring wheat accounts for about 50% of the cash value of North Dakota crops, other products in order of their importance being barley, flaxseed, durum wheat, oats, potatoes, soybeans, sugar beets, corn and hay. Income from livestock and livestock products rose steadily in importance, with cattle and calves accounting for more than half. Dairy products were second, followed by hogs and poultry. Pig production increased rapidly after the development and promotion of pelleted barley as a new hog food by the North Dakota agricultural experiment station. North Dakota farmers have pioneered in the organization and operation of co-operative marketing and purchasing associations. After World War II co-operative marketing increased and there was some expansion of consumer co-operative activities.

Water Development.—An extensive water-development program was undertaken in North Dakota under the Missouri River Basin Development program authorized by congress in 1944. Participated in by both federal and state governments, the program was designed to provide irrigation, power, water supply and recreational activities for the people of the state. Garrison dam on the Missouri is one of the largest earth-filled dams in the world. Other dams included in the program were Dickinson and Heart Butte dams on the Heart river, Jamestown on the James, Baldhill on the Sheyenne and Homme on the South branch of the Park.

Industry.—Handicapped by climate, distances from eastern markets and centres of population, high transportation costs, and with local raw materials limited largely to agricultural products, industry in North Dakota has grown slowly. Manufacturing establishments tend to be small and to produce low-cost items. Flour mills are scattered throughout the state. Various meat-packing activities are carried on in different parts of North Dakota. Grand Forks, located in the potato area, has several industries based on that crop; and Dickinson, in the coal-mining region, produces 35,000 tons of lignite briquettes annually. The processing of dairy products is increasing in importance.

Mining.—Lignite deposits in the western two-thirds of the state are estimated to cover 32,000 sq.mi.; almost 90% of them are workable. Coal-mining operations have been carried on in western North Dakota since the time of the earliest ranching. Most of the commercial lignite mines are of the strip type. The bringing in of an oil well in April 1951 in the northwestern part of the state opened a new area of activity, and by the late 1950s more than 1,175 wells were in operation in about 60 fields, most of them in the western and northwestern parts of the state. About 1,100 cu.ft. of wet gas are produced for each barrel of oil. There are extensive deposits of clay, sodium sulfate, salt and sulfur.

Transportation and Communication.—The state is served by four large railroad systems operating over more than 5,000 mi. of track. The Great Northern system serves the northern section of the state and the Northern Pacific covers the southern part. The Minneapolis, St. Paul and Sault St. Marie, more often called the Soo line, covers most of the northern and eastern sections, while the tracks of the Chicago, Milwaukee, St. Paul and Pacific are located in the southwest corner of the state. North Dakota has more than 6,000 mi. of primary state highways. Trunk airlines serve the state along with local service carriers.

The first newspaper in North Dakota, the *Bismarck Tribune*, was established in 1873. In 1874, the *Fargo Forum* was founded as the *Fargo Express* and five years later the *Grand Forks Herald* began publication. In the 1960s the state had about 120 newspapers, about 100 of which were weekly, and 18 periodicals. The first broadcasting station, WDAY, was established in Fargo in 1922 and in the 1960s there were 12 radio stations and 10 television stations in operation.

Current statistics on production, employment, industry, etc., may be obtained from the pertinent state departments; the principal figures are summarized annually in the *Britannica Book of the Year*, American edition. (H. E. B.)

NORTH EAST FRONTIER AGENCY, a wild tangle of sparsely populated mountainous country in the extreme northeast of India, stretches broadly from the Brahmaputra river plain in Assam northward to the main crestline of the Assam Himalayas and eastward to an irregular line passing through a series of lofty peaks, known as the "hump" during the World War II airlift to China. Geographically and constitutionally, the agency is a part of Assam (*q.v.*). Pop. (1961) 336,558; area 31,438 sq.mi., but the frontiers have never been surveyed in detail and marked out on the ground. The agency (N.E.F.A.) comprises five frontier divisions. Kameng in the west adjoins Bhutan; eastward of this is Subansiri and then Siang frontier division (*q.v.*). At the blind eastern end of the Assam valley is Lohit, while Tirap lies to the south on the Burmese border. The area is intersected by rivers; its greater part has a heavy rainfall and is thickly forested. It is inhabited by tribes mostly of Mongoloid stock such as the Monba, Mishmi, Abor, Miri, Dafla and Aka, each occupying roughly defined tribal areas. They are mostly animists and practise shifting cultivation. The agency is administered by the governor of Assam as agent of the president of India, assisted by an adviser in Shillong (agency headquarters). Difficulty of communications is one of the agency's major problems. In 1957 several airstrips were commissioned and others were planned. The various administrative centres and outposts are linked by radio.

The northern boundary, about 550 mi. long, in dispute between India and China, is known as the McMahon line because Sir Henry McMahon was secretary in the Indian foreign department and represented Great Britain at the conference held in Simla (1913–14) to settle frontier and other matters relating to Tibet. The line was regarded by the British as the natural, ethnic and administrative boundary. Representatives of Britain, China and Tibet agreed that the frontier between Tibet and northeast India should follow the crest of the high Himalayas. Two days later the Chinese republican government disavowed its plenipotentiary and refused to sign a convention. Prior to that the British-Indian government had made agreements with the indigenous tribes and set up the Balipara frontier tract in the west and the Sadiya frontier tract in the east, together constituting the North East Frontier agency (1912–13) and including undoubted Assamese territory.

After the independence of India in 1947, China made claims to practically the whole area covered by Kameng, Subansiri, Siang and Lohit, arguing that the McMahon line had never been accepted by China and was the result of British "aggression." In letters to the Indian prime minister, Jawaharlal Nehru, the Chinese prime minister, Chou En-lai, quoted a map in the 1929 edition of *Encyclopædia Britannica* showing the disputed territory as Chinese, with the boundary following the alignment of Chinese maps. Some Chinese maps before 1935 have shown N.E.F.A. as part of India, and since then as part of Tibet. The *Survey of India* (1883) showed the disputed tribal areas as *de facto* administered by British India. British and Indian maps since 1914 have usually followed the McMahon line. If the Chinese claims were allowed, the Indo-Chinese border would follow roughly the margin of the Assam plain, a frontier almost impossible to defend. Following this dispute Chinese troops crossed the McMahon line on Aug. 26, 1959, and captured an Indian outpost at Longju, a few miles south of the line. They abandoned this in 1961 but in Oct. 1962 crossed the line, this time in force. After first striking toward the Tangla ridge and Towang near the Bhutan border the Chinese later extended their attack along the whole frontier. Deep inroads into agency territory were made at a number of points. Later the Chinese agreed to with-

draw approximately to the McMahon line and in 1963 returned Indian prisoners. *See* INDIA: *History*. (L. D. S.)

NORTHERN DESERT TERRITORY (AL BADIYAH ASH SHAMALIYAH), a region of Iraq, originally formed after 1947 as a *liwa'* (province), along with the Southern Desert territory and Al Jazirah, from what had previously been termed tribal areas and left undemarcated. Area 39,127 sq.mi. As late as 1941 the western margins of certain provinces in Iraq containing a significant proportion of nomads did not have precisely defined western boundaries, and the delimitation of the three desert provinces completed the administrative structure of the country. The Northern Desert territory includes the greater portion of lands lying west of the Nasiriyah and Karbala provinces, including the extension of Iraqi territory to meet the frontiers of Jordan and Syria. The inhabitants, mostly nomadic, are mainly Dulaim and Ruwalla tribesmen, and as there is much seasonal movement the population numbers fluctuate considerably. By 1960 the region had been administratively attached to the settled *liwa'*. (W. B. FR.)

NORTHERN IRELAND: *see* IRELAND, NORTHERN.

NORTHERN LIGHTS: *see* AURORA POLARIS.

NORTHERN NIGERIA, the largest of the federation's three regions, had a population of 29,808,659 at the 1963 census. Its area of 264,282 sq.mi. covers more than three-quarters of Nigeria. Most of the region lies north of the Niger and Benue rivers, with Ilorin province and parts of Kabba and Benue provinces to the south. From the low-lying valley country the ground rises to 1,000–2,000 ft. over large areas, to 4,000–5,000 ft. in the Jos plateau and to over 6,000 ft. in the Adamawa highlands. In the northeast the land slopes gradually down to the great inland drainage basin of Lake Chad (*q.v.*). Major river systems flow to the Niger (Sokoto and Kaduna rivers), to the Benue (Gongola and Katsina Ala) and to Chad (Komadugu Yobe), but only the largest rivers are perennial. During the continuous dry season of varying length (4–9 months) agricultural activities are reduced to a minimum and there are severe water supply problems; for part of this season the dry harmattan (*q.v.*) wind from the Sahara intensifies aridity. Rainfall varies from 20 to 60 in. and should suffice everywhere for cultivation, but is often variable and unreliable. Temperatures are generally high throughout the year rising to well over 38° C. (100° F.) during the hottest season. Vegetation ranges from savanna, with considerable tree growth (particularly in the river valleys) in the south, to acacia scrub on the northern borders, but there is no desert.

In the northernmost provinces peoples speaking Hausa and Fulani (*qq.v.*) form the majority of the population except for an important group of Kanuri (*q.v.*) people in Bornu province. Of the many smaller and varied groups farther south in the middle belt, the Nupe, Yoruba and Tiv (*qq.v.*) are the most important. About three-quarters of the total population are Muslims; most of these are in the north with pagan peoples in the middle belt. Only 3% profess Christianity.

In culture and administration the Hausa-Fulani-Kanuri areas are traditionally more advanced than the rest of the region. In the northern emirates Frederick John Dealtry Lugard (*q.v.*) introduced a system of indirect rule and even with modern political developments the emirs and the native administrations, particularly the larger emirates of Kano, Sokoto, Bornu and Katsina, remain powerful. Northern Nigeria became self-governing within the federation in 1959. Representatives are elected by adult male suffrage to a house of assembly from which the regional government is formed. There is also a house of chiefs. The regional capital is Kaduna (*q.v.*) where Lugard established the headquarters of the Protectorate of Northern Nigeria. Social services are limited though great advances have been made in medical and educational facilities, and important campaigns have been conducted against malaria and sleeping sickness. About 250,000 of the children in the region attend school. Ahmadu Bello university was opened at Zaria (*q.v.*) in 1962.

Agriculture is the basis of the economy both for subsistence and in production for export. There persists a sharp distinction between cultivators and pastoralists, most of the latter being nomadic Fulani who move their herds in search of pasture and water. But their migrations are restricted by tsetse-fly infestation affecting two-thirds of the region. Some progress has been made in developing mixed farming but fertility is generally maintained by leaving the land fallow for varying periods. In some areas the pressure of population has caused deterioration of the land, in others (notably Kano) numerous people are supported by intensive cultivation. Over much of the region cereal crops (sorghums and millets) are the staple foods, though in the south root crops (cassava and yams) are cultivated. Peanuts (groundnuts) and cotton are the main exports, though hides and skins are also important. These cash crops are also consumed within the region and are fully integrated into the indigenous agricultural systems. A sugar plantation and a refinery were established at Bacita in the Niger valley in the early 1960s. Tin and columbite are mined on the Jos plateau and adjacent areas. International restrictions on tin production, imposed in 1958, were removed in 1960. Deposits of low-grade iron ore exist near Lokoja at the Niger-Benue confluence. Many local crafts are practised but modern industries are few. Small industrial areas have developed at Kaduna and at Kano, where a modern textile plant produces cotton cloth and a type of calico known locally as baft. There are small hydroelectric power installations on the Jos plateau. In the 1960s construction of the Kainji dam marked the first stage of the Niger dams project.

Until the 20th century all trade from this part of west Africa was with lands to the north, from the great markets of Kano, Katsina, Sokoto (*qq.v.*) and Kuka. Remnants of trans-Saharan trade by camel caravan include the bringing of salt from the Sahara, but most of the region's external trade passes from or to the coast by road, rail or river. Lack of communications restricts economic expansion in some areas. A major extension of the railway from near Jos through Bauchi and across the northeast of the region reached Maiduguri in 1964. Kano is the premier commercial centre of Northern Nigeria and its airport is one of the main air junctions of Africa.

The two areas along the eastern border of the region forming the United Nations trust territory of the Northern Cameroons were incorporated in Northern Nigeria following a plebiscite held in 1961. For the provincial subdivision of the region *see* NIGERIA: *Administration and Social Conditions*. *See* also ADAMAWA; BORNU; ILORIN.

Pugh, *Land and People in Nigeria* (1955); Northern Nigeria Information Services, *Social and Economic Progress in the Northern Region of Nigeria* (1957) (R. M. P.)

NORTHERN PROVINCE, CEYLON, covers an area of 3,429 sq.mi. and had a population (1960 est.) of 690,000. It falls into two contrasting parts. The northern and smaller part is made up of the Jaffna peninsula and an associated group of small islands and although it has only about one-ninth of the area of the province it accounts for nearly six-sevenths of its population. The peninsula and the islands alike consist of Miocene coral reefs that have been raised above sea level, so that the bedrock is almost everywhere coral limestone. In places this is exposed, giving barren, rocky country, but much of the limestone is covered with sand with gray loams, or with fertile red soils. The limestone, being fissured, holds plentiful supplies of water, and it is perhaps to this more than to any other single factor that the dense population may be attributed. The peninsula is deeply intersected by an intricate network of lagoons, and would itself become a series of islands cut off from the mainland of Ceylon, given a very slight rise of sea level. The coast is low, made up of sandbars and miniature cliffs. The rest of the province is part of the mainland and is mostly a gently undulating lowland, much of it between 100 and 130 ft. above sea level, and floored by ancient crystalline rocks. In a strip down the northwest coast, including the Mannar Island, these outcrops are a version of the Jaffna limestones, while opposite Mannar Island, and again behind the lagoons of the northeast coast, there are stretches of usefully fertile alluvium. The coast is generally low, and on the east made up very largely of lagoon-enclosing sandbars, one of which links the Jaffna peninsula to the mainland.

The whole of the Northern province falls climatically within

Ceylon's lowland dry zone, with its marked alternation of heavy rains during the northeast monsoon and severe drought during the southwest (*see* CEYLON: *Physical Geography*). The Jaffna peninsula in fact suffers this seasonal rhythm in an exaggerated form, being particularly liable to long and searing drought; its underground water supplies are then a great boon. Much of the mainland part of the province is still covered with the jungles of the *Wanni*, to use its traditional name, though the Jaffna peninsula and islands, together with Mannar Island and much of the alluvium, have for the most part been cleared for cultivation.

The mainland part of the province contains many irrigation works and inscriptions testifying to its settlement in ancient times. The Jaffna peninsula originally had Sinhalese inhabitants, but from about the 2nd century B.C. onward Tamils from India made settlements there and along the coast of the mainland. The vast majority of the province's population are now Ceylon Tamils, though there is a group of Sinhalese villages in the southern *Wanni* and a number of Moors (Muslims) in Mannar. The chief town and provincial capital is Jaffna (*q.v.*).

Rice is grown on the gray loams of the peninsula and on alluvium and under tank irrigation on the mainland. Coconuts cover a sizable area in the peninsula, on Mannar Island, and on some of the coastal sandbars. The peninsula is also important for the intensive cultivation of tobacco, vegetables and other crops. Jaffna and other towns manufacture *bidis* (local cigarettes) and carry on a brisk trade in small ships with south India. (B. H. F.)

NORTHERN PROVINCE, SUDAN, the northernmost province of the Republic of the Sudan, extends southward to roughly latitude 17° N. and eastward mostly from longitude 27° 30' to about 34° E. Area 184,198 sq.mi. Pop. (1963 est.) 1,075,-250. The regional headquarters are at Ed Damer (1956 pop. 5,458), and the province is divided into five administrative districts. It was formed in 1935 from Halfa, Dongola and Berber provinces and it lies within the historic region of Nubia (*q.v.*).

The agricultural and settled area of the province is only about 500 sq.mi., restricted mainly to a narrow strip of alluvial land on either side of the Nile (*q.v.*). Granitic rocks of the basement complex along certain stretches allow the river to cut for itself only a very narrow bed with limited patches of cultivable land. Such reaches often have rocky bars causing cataracts and rapids. Where the river runs through rocks of the Nubian series, it carves a wider bed flanked by broader terraces. Because such areas are normally flatter, as in the Dongola reach, the river's meander through them has left basins or depressions which were once part of the river bed.

Most of the region is, in strong contrast, a flat Saharan desert plateau, with sand dunes, sandsheets and scattered hills. The eastern or Nubian desert is characterized by bare rocky hills which have been worn down to a featureless plain. Igneous and metamorphosed rocks of the basement complex appear at the surface, which is stony or sandy. Only a few big granitic hill masses are to be seen. In the western or Libyan desert the land is flat chiefly because of erosion under arid conditions and the nature of the underlying rock. The plain is of nearly horizontal sandstones and mudstones of the Nubian series, with a few outcrops of dissected hills of the basement complex. In some places, on both sides of the Nile, wadies interrupt the dead features of the plain.

The climate is extremely hot in summer and unexpectedly cold in winter. The prevalent wind is from the north during November–April and from the south during May–October (except in the Wadi Halfa district where southerly winds are exceptional). Sandstorms occur frequently between April and July. North of Atbara the region is virtually rainless, but in the south it receives an annual average of 6 in. On the desert plateau the vegetation reflects rainfall conditions, but the banks of the Nile show a different pattern. North of Atbara some vegetation exists in wadies and depressions stretching out from the river; otherwise desert conditions prevail. South of Atbara begins the acacia desert scrub region some of the plains being covered with drought-resisting trees and shrubs which can survive the dry season; but some areas have no trees and few shrubs. Along the banks of the Nile the vegetation is more plentiful, with date and doum palms.

Besides Ed Damer, the largest towns of the province (1956 pop.) are Atbara (36,298), Wadi Halfa (11,006) (*qq.v.*), Berber (10,-977) and Shendi (11,031). The railway shops at Atbara and the cement factory south of it offer employment to some of the people, but the economy of the province is predominantly agricultural. Rain cultivation is practised, to a variable degree, only south of Atbara. Irrigation is necessary for all important crops; thus the province's prosperity depends on the Nile. Methods of irrigation are inundation during high flood, basin irrigation, *sakia* (sakieh) and *shaduf* (shadoof) irrigation (*see* EGYPT: *Methods of Agriculture*), and systematic irrigation by pumps. The main commercial crops are dates, citrus fruits, mangoes and pulses (horse beans, haricot beans, etc.). Subsistence crops include vegetables and cereals. The cash crop (dates) of the Wadi Halfa district finds its markets mainly in Egypt, but most of the rest of the province looks southward to Khartoum and eastward to Port Sudan for the disposal of surpluses.

Because of cataracts, river transport is limited to certain stretches. A regular steamer service connects Karima (Kuraymah) with Kerma (Karmah), and another runs from Wadi Halfa to Aswan in Egypt. The main railway line from Khartoum to the north follows the Nile to Abu Hamed where it crosses the desert to terminate at Wadi Halfa. Branch lines run from Atbara to Port Sudan and from Abu Hamed to Karima. Motor transport serves most of the inhabited parts. There is an airport at Wadi Halfa and a smaller one at Atbara. (A. EL-S. O.)

NORTHERN REGION, GHANA, an administrative division, lies between Upper region to the north and Brong-Ahafo and Volta regions to the south. It extends across the republic from east to west. Pop. (1960 census) 531,573. Area 27,175 sq.mi.

The region belongs chiefly to the vast basin of the Volta and its main affluents, the Black and White Voltas, and, in the east, the Oti. It is floored with Paleozoic sediments in which sandstones predominate, flanked on the west by a continuation of the peneplain of Pre-Cambrian metamorphic and igneous rocks found in southern Ghana, of average altitude 1,000 ft. A prominent erosional scarp near Gambaga and a lesser one at Konkori mark respectively the northern and western edges of the Voltaian basin, but otherwise it has a gently undulating surface.

Climatic conditions are generally harsh. The annual rainfall, which is highly variable ranges from 50 in. in the south to less than 40 in. in the north and is concentrated into a single season followed by five months of drought, during which even the larger streams shrink sufficiently to permit crossing by drifts at a number of points. The vegetation is Guinea savanna woodland, much degraded by burning and cultivation. Soils vary with the underlying rock, the best and most friable being the ochrosols developed on the older rocks in the west and north, while the Voltaian sandstones within the basin usually produce thin, dry lateritic soils.

Most of the inhabitants appear to be elements of recent migrations and invasions from the north, and the tribal and ethnic pattern is extremely complex. Distance from the sea and the consequent feebleness of European influences greatly retarded the economic development of this region. The overall population density is low, partly because many workers emigrate southward in search of better opportunities in the mines, cocoa farms and urban centres of southern Ghana, but principally because of the widespread aridity and the ravages of tsetse diseases and river blindness (onchocerciasis), especially prevalent along the headwaters of the White Volta.

Large towns are few, most of the population concentrations being found in the "compound villages" of round, thatched-roofed conical huts scattered amid cultivated fields, which are commonest north of Tamale, the regional capital. Tamale (*q.v.*; pop. [1960] 40,443) is the largest town, followed by Yendi (16,096) and Savelugu (5,949). The Northern region was constituted with eight administrative districts but in the early 1960s the number of these was increased by an ordinance conferring district status on all local and urban councils.

The main occupation is subsistence agriculture of the land rotation type based on the cultivation of millets, guinea corn and pulses in the northern parts and of yams, rice and cassava farther south, but there is a notable export of yams to other regions. Shea but-

ter, obtained from the fruits of the wild shea tree, is both an important local staple and an export item. This region is one of Ghana's chief potential sources of beef cattle, and further expansion of the industry was envisaged in the 1960s. A large veterinary station is located at Pong Tamale, 20 mi. north of Tamale. Mixed farming has been introduced and has gained ground under government sponsorship. Another significant government undertaking is the land-planning scheme centred at Damongo, near the Mole game reserve, for the resettlement of farmers from the overcrowded Fra Fra areas of the Upper region. The leading commercial crop around Damongo is tobacco.

Communications are generally poor; there are no railways and most of the main roads are primarily links with the south, with few east–west connections. Donkeys are employed on a limited scale for local transport, and the use of bicycles has spread among the farming populace. Tamale, around which commercial agricultural activities are mostly concentrated, is the principal focus of roads and the northern terminus of Ghana's internal air services. (Er. A. B.)

History.—The history of the Northern and Upper regions may conveniently be combined. The Gur-speaking peoples of the area were originally organized in many small independent kinship groups each under the most suitable male member, whose functions were as much socio-religious as political. From about the 13th century this situation changed through the influence of peoples developing trade and empire farther north by trans-Saharan contact with the Muslim civilization of north Africa. Invaders from the north and northwest created the first Akan (*q.v.*) states; *e.g.*, Banda, just north of the forest. These were soon subject to pressure from mounted warriors from the northeast who, by the 15th century, had organized two major kingdoms, Dagomba (*q.v.*) and Mamprusi, by imposing themselves as an aristocracy upon the local kinship groups. Elements of this aristocracy later created similar smaller states such as Wa in the west and Bimbila south of Yendi. Islam was brought to Dagomba and Mamprusi late in the 17th century by Hausa traders from the northeast, but meanwhile another Muslim influence, that of Mande (Mandingo, *q.v.*) traders and settlers from the northwest, had given rise to the rival state of Gonja (*q.v.*). During the 17th century, Gonja expanded northeastward at the expense of Dagomba, which sought compensation in new conquests farther east. In the 18th century, following the development of trade on the Gold Coast, the Akan empire of Ashanti (*q.v.*) began to raid and conquer north of the forest at the expense of Banda, Gonja and Dagomba, which became tributary states. The 19th century was one of increasing disorder because of the decay of the old trade routes to the north and of Ashanti power in the face of British advances. Much of the area was eventually overrun from the west by the Mande empire-builder, Samory, or subjected to the slave raids of Babatu's Zaberma (Songhai) from the northeast. In the 1890s, following the British conquest of Ashanti and in face of rival French and German advances, small columns of British troops organized what in 1902 was recognized as the Northern Territories protectorate, administered by a chief commissioner responsible to the governor of the Gold Coast. In 1957 the protectorate was ended when the territory became an integral region of Ghana. Northern region was in 1960 subdivided into Northern and Upper regions. (J. D. F.)

NORTHERN REGION, TANGANYIKA, renamed Arusha Region following a reorganization of administrative units in Tanganyika in May 1963, when the Kilimanjaro (Moshi) district was detached from it, is bounded north by Kenya, east by Kilimanjaro and Tanga regions, south and west by Dodoma and Singida regions, and northwest by Shinyanga and Mara regions. Area 31,900 sq.mi.; pop. (1963 est.) 447,630. It is a region of striking and attractive contrasts; to the northwest are the Serengeti plains, to the southeast the monotonous expanses of the Masai steppe, broken only by gneiss inselbergs. In between are the escarpments and hills, the Crater highlands, bordering the southern and branching portions of the Great Rift valley (*q.v.*). Volcanic activity associated with Tertiary faulting has produced wide lava plains and great volcanic massifs; such as Meru (14,979 ft.), the Ngorongoro crater, Hanang (11,215 ft.) and Oldeani (10,400 ft.). Mt. Ol Doinyo Lengai, near the Kenya border, is still occasionally active.

The drainage in the west is to the Rift valley lakes of Natron (soda lake, partially in Kenya), Eyasi and Manyara, but is separated by only a low watershed from drainage to Lake Victoria. Streams rising on Meru flow southeastward to the Pangani river and the Indian ocean. The mean annual rainfall varies widely with relief and aspect. The well-watered southern and eastern slopes of Meru (70 in.), exposed to the prevailing winds, contrast with the semiarid plains where rainfall is marginal and unreliable (less than 20 in.). Maximum rainfall is from March to May, with a marked dry season from June to October. Temperature varies with altitude, so that above the hot plains, near-temperate conditions are found on the highlands. Some of the most fertile soils in the country are volcanic soils on the mountain slopes. Plain soils, not leached, are characteristic of the Masai steppe with red earths on foot slopes. Vegetation types reflect the variety of climates: wooded savannas, montane forest on the moist slopes to about 9,500 ft., and Afro-alpine communities at higher altitudes.

The Serengeti National park (4,250 sq.mi.), part of which is in Northern region, has a wealth of wild life unexcelled in Africa. At Olduwai gorge, near Oldeani, the skull of an early stone-tool-making man of the australopithecine group was found in 1959. (J. M. Ke.)

In the Arusha district the Arusha numbered 68,100 at the 1957 census and the Meru 35,600. The Mbulu district is notable for having its chief tribes of widely differing origins, who are unintelligible to each other linguistically. They are: the Iraqw, 134,000; the Barabaig, 27,500; and the Mbugwe, 6,300. The 50,100 Masai share their large area with about 4,700 Sonjo and 1,000 primitive Dorobo hunters. There are some European settlers on the slopes of Mt. Meru and about 200 elsewhere in the region. The regional headquarters is at Arusha (pop. [1957] 10,038), at the foot of Mt. Meru.

The region is an important coffee-producing area, the crop being grown by both Africans and non-Africans. Other crops are maize (corn), beans, onions, cotton, pyrethrum, papain, sunflower and castor seed, groundnuts (peanuts) and wheat. The cattle trade is a feature of the economy, the Chagga (Kilimanjaro region) being the main purchasers and the Masai the main sellers. Some areas, especially in the Mbulu district, are tsetse infested. At Tengeru is a natural resources training school for agricultural and veterinary staff. Few minerals of any importance occur with the possible exception of meerschaum near the Kenya border, but active prospecting has continued.

The region contains some of the best big-game shooting grounds in Tanganyika, as well as the well-known game-filled Ngorongoro crater. More easily accessible but not so well known is the crater at Ngurdoto near Arusha, where elephant, rhinoceros, buffalo and other game can be seen at all times. Another national park is situated at Lake Manyara. Some of the rivers are stocked with trout.

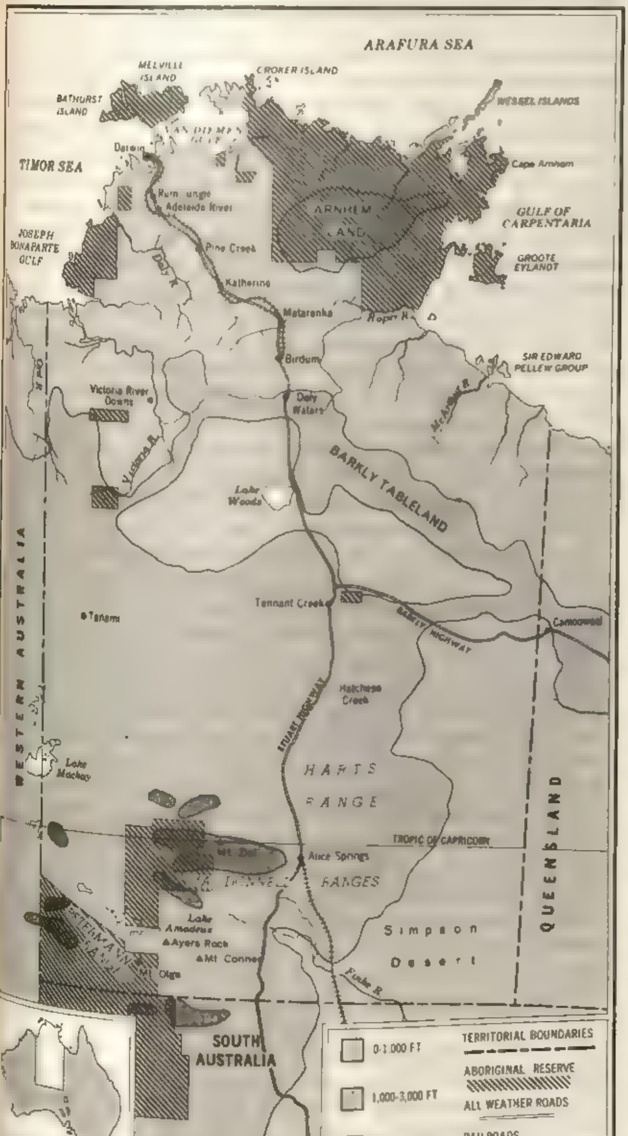
Arusha is the terminus of the Tanga railway; main roads link the town with Nairobi (north) and Mombasa (east) in Kenya, as well as with Tanga on the coast and Iringa and Mbeya (south).

NORTHERN SEA ROUTE, the name given in the U.S.S.R. to the Northeast passage, is a system of navigable waterways running along the Siberian coast of Asia. It has been much developed by a Soviet government department, Glavsevmorput, since 1932. The major freighting operations are transporting timber from the Yenisei (Igarka), and supplying the settlements of the far northeast. Ice has hitherto limited operations to only 8–16 weeks during July–October, even with icebreaker and aircraft support, but scientific and technological advances may extend the season. See Arctic, The. (T. E. A.)

NORTHERN TERRITORY, AUSTRALIA, one of the two federally administered territories of Australia (the other is the Australian Capital Territory), occupies the north-central part of the continent from latitude 26° S. to the northern coast and from longitude 129° E. to 138° E., lying almost wholly in the torrid zone, north of the Tropic of Capricorn. Area 520,280 sq.mi.

It is extensively but sparsely settled: pop. (1961) 46,799; density 0.09 per square mile. Darwin on the Timor sea, the chief port, is the administrative centre for the territory, and Alice Springs is the principal centre for the south.

Physical Features.—Much of the country is featureless. The indented coast, nearly 1,000 mi. long, is low, flat and generally thickly fringed with mangroves. Occasional sandstone marl and ironstone headlands, seldom as high as 100 ft., separate the sandy beaches and mud flats of the river estuaries. The largest rivers are the Victoria, entering the Timor sea near the northwest boundary of the territory, the Daly farther toward Darwin, the Roper flowing to Limmen bight on the western side of the Gulf of Carpentaria, and the McArthur about 120 mi. farther east. They flow from an area with lower rainfall to one with higher rainfall, and, though they are substantial streams in the wet season, they may become little more than a string of water holes during the dry season. Part of the highlands forming the watershed of these rivers is the Barkly tableland, whose northeastern edge runs roughly parallel with the coast of the gulf and about 100 mi. from it. This tableland, which, with the Victoria river district, contains the best grazing lands of the territory, is really the northeastern extension of the great plateau or Australian shield that stretches across Western Australia and covers more than half the continent. On the southwest side of the Barkly there is a gradual rise from about 700 ft. to over 1,000 ft. Northwestward there is a fairly



SURFACE FEATURES AND ABORIGINAL RESERVES OF THE NORTHERN TERRITORY

rapid falling away to the low plain bordering Joseph Bonaparte gulf. South of this area, with normal drainage to the coast, lies a shallow basin centred on Lake Woods, a marshy swamp that can become an extensive sheet of shallow water in the wet season. A further slight upward warp to the south separates the Lake Woods drainage area from that of Lake Eyre, in northeastern South Australia. None of the territory's rivers rising in the highlands of central Australia reaches Lake Eyre, and most have water in them only after rains. These tree-fringed courses usually have beds of water-bearing sand. The Macdonnell ranges, trending east and west and formed chiefly of gneisses and schists, rise to peaks of about 5,000 ft. Southwest of the Macdonnells, between them and the Petermann ranges, is another depression, Lake Amadeus. This "lake," about 90 mi. long and 2–15 mi. wide, is really an area of salt or dry salt-encrusted mud. To the south of Amadeus and at some distance from each other lie the huge monoliths known as Ayers Rock, Mt. Olga and Mt. Connor, famous for their grandeur and brilliant colour effects. The 300,000-ac. Ayers Rock-Mount Olga National park was established in 1958.

Climate.—The main characteristic of the climate throughout the Northern Territory is the markedly seasonal character of the rainfall. The whole territory has a dry winter (May to October): Darwin's total rainfall for the four months May–August averages less than ½ in., and that about 300 mi. south at Victoria River Downs homestead less than 1 in. for the six months May–October. The rainfall of the Alice Springs area, averaging between 9 and 11 in. per annum, is more regular than is usual in these arid lands; elsewhere the rainfall in the wet season shows great variations from year to year. Darwin's annual average is 59 in., whereas the southeast corner of the territory falls to an average as low as 5 in. (Simpson desert). Temperatures range from a mean maximum of 32° C. (90° F.) to a mean minimum of 24° C. (75° F.) at Darwin and from a mean maximum of almost 38° C. (100° F.) to a mean minimum of about 4° C. (39° F.) in the south.

Vegetation.—The climate and the generally poor soils associated with it give rise to tropical savanna vegetation over much of the area. The northern lowlands are covered with tall grasses of little value and sparse tree growth, which includes cypress pine (*Callitris intratropica*), ironwood (*Erythrophleum chlorostachys*) and paperbark, or bottle-brush plants (*q.v.*); these trees are cut and milled for local building use, being resistant to termites, but they were much reduced by their use for troops during World War II. Farther inland, especially on the Barkly tableland and parts of the Victoria river district, there are better perennial grazing grasses and some shrubs. Between the Barkly tableland and the ranges of the Alice Springs area a wide belt of sandy country is covered mainly with spinifex grass and low scrub; the Alice Springs ranges and uplands carry chiefly mulga, or dwarf acacia scrub, spinifex and other sparse grasses.

Animal Life.—This is similar to animal life elsewhere in tropical Australia and includes kangaroos and wallabies, crocodiles, a great variety of birds, snakes (many nonvenomous), frogs and freshwater fish. Buffalo, introduced from Timor in the early days, flourished in the far north and are now shot (under licence) for their hides. Gnats, mosquitoes and other insects are troublesome during the wet season, and termites are a considerable menace to construction in timber.

History.—Abel Tasman sailed along the Northern Territory coast in the 16th century. Malays and Indonesians visited the waters for bêche-de-mer and pearls. Matthew Flinders was the first to chart the coast on his voyage of 1803. In 1818 a further coastal exploration under Phillip King mapped some of the river mouths and inlets, including the opening of the harbour on which Darwin was later founded. Attempts at military settlement were made at Ft. Dundas on Melville Island (1824), at Raffles bay and at Port Essington (1838). In 1849 the Port Essington attempt was given up. These early settlements were mainly designed to forestall Dutch annexation. Since they were isolated and distant from any useful farming land, no permanent nonmilitary settlement resulted.

In 1862 John McDouall Stuart crossed the territory from South Australia to the mouth of the Adelaide river, the first crossing

of the continent from south to north. South Australia claimed the new territory, and despite other proposals the colonial secretary agreed that South Australia should administer it. Administration was organized, not overland from Adelaide, which would have involved regular crossing of the forbidding arid country of northern South Australia, but by sea, at first at a settlement near Adelaide river, then at Palmerston (later called Darwin). The building of the overland telegraph from Adelaide to Darwin in 1872 was the great achievement of this period. Running through nearly 2,000 mi. of unoccupied and largely desert and semidesert country, the line was finished within two years and remained the only telegraph in the territory until 1940.

Efforts to develop pastoral and agricultural industries, especially the growing of sugarcane, rubber and coffee, met with little success because of the rather dry monsoonal climate, the great distances and the unattractive land tenure system adopted. Chinese were imported to work on prospective plantations and on public works, but they joined in the gold rushes of the late 1870s, the only activity that drew many people to the territory, though they proved disappointing. There were more nonaboriginal people in the area during the census of 1891 than there were again until that of 1947. Railways were built by the South Australian government in the territory from Darwin 125 mi. S.S.E. to Pine Creek and in South Australia from Port Augusta on Spencer gulf (in the south) to Oodnadatta, within 300 mi. of Alice Springs, then a little settlement at the telegraph station.

On taking over the territory from South Australia in 1911, the Australian commonwealth government paid the state £4,000,000 compensation and bought the Port Augusta-Oodnadatta railway for another £2,250,000, agreeing also to extend the line to Alice Springs, which was done in 1929. It also agreed to continue it to Darwin at some future date. Commonwealth control began at a time when the efforts of the South Australian government were flagging in face of the difficult conditions. The population had fallen below 3,000, little more than half the number in 1890; there were only about 500,000 head of cattle; and little of the pastoral land was effectively occupied. In the next 20 years little progress was made, in spite of considerable expenditure; but the railway milage was nearly doubled, and the railway deficit much increased. A number of expert reports on various aspects of Northern Territory problems were commissioned by the commonwealth government from 1913 onward, and various changes in administration and direction of effort were made. In the 1920s the territory was split into Central Australia and Northern Australia but was reunited as Northern Territory in 1931. The territory remained a problem area, with much-publicized labour disputes in Darwin and little progress anywhere.

Darwin received a stimulus from the development of air services during the 1930s and from its use as a fueling centre and defense base for army, navy and air force. The Japanese threat to northern Australia, the bombing of Darwin in 1942 and the establishment of troops throughout the north led to greater interest in northern Australia generally. After the war more intensive surveys of both land and mineral resources were made, development was encouraged and a more advanced policy for the welfare of aborigines was formulated. The granting of voting rights to all full-blooded aboriginals was announced in 1962. Enrollment at special schools for aboriginals reached 2,500 in the early 1960s as compared to fewer than 500 as late as 1950. (*See* also AUSTRALIA, COMMONWEALTH OF: *History*.)

Population.—The 1961 census showed a nonaboriginal population of 27,095 (61% more than in 1954). Disparity between the sexes was always high among Europeans but has decreased, there being about 3 males to 2 females. There are only two substantial centres of population, Darwin (12,326 in 1961) and Alice Springs (4,648). Tennant Creek, main centre for the mining industry, has a population of about 1,400, and Katherine, centre of the northern cattle industry, about 800. Most of the nonaboriginal population is in these centres, about 70% being classed as urban. Full-blooded aboriginal population is increasing and in 1961 was estimated at about 17,500; there are also about 2,000 part aborigines.

Aboriginal Reserves.—Seventeen reserves with a total area of approximately 67,000 sq.mi. have been set aside for the aborigines. Some of these are small areas near towns, and many are in poor and arid country. The largest, Arnhem Land, is not well explored but is known to contain some relatively good land well supplied with game and fish. Other large reserves are Haast Bluff in the arid southwest, and reserves on Bathurst and Melville islands, Groote Eylandt and small islands like Croker, Goulburn and Elcho. There are 14 mission stations of four denominations said to be in more or less close touch with about 5,000 aborigines and receiving government subsidies.

Administration and Social Conditions.—*Government.*—A measure of constitutional reform was adopted in the passing by the commonwealth parliament of the Northern Territory (Administration) act, 1959. Under this act the legislative council was enlarged and its powers slightly increased, but its ordinances must still be approved by the administrator, who is both its president and the chief executive officer, or by the governor-general. A new (advisory) administrator's council, nominated by the administrator, was set up at the same time. The territory elects a member to the house of representatives of the commonwealth parliament. He has the right to take part in debates but not to vote.

Education.—Facilities for education are being expanded fairly rapidly. Schools are built by the commonwealth government, which also reimburses the South Australian department of education for the cost of providing staff and school services within the territory. In the 1960s there were 20 government schools, with an enrollment of over 4,500, of which about one-third were part-aborigine and Asian children, and 4 private schools, with a total of over 800 pupils. In addition, nearly 150 studied with the South Australian correspondence school, aided by the School of the Air, inaugurated in 1950 with two-way radio communication through the Alice Springs base of the Royal Flying Doctor service (*see* below). Beginning in 1949 several schools were established for aborigines, and by the 1960s there were 34 special schools, about half conducted by missions and half by the territorial administration welfare branch. A few were established on pastoral stations. Three preschool centres were conducted for aboriginal children. Aboriginal schools have a special syllabus, and free midday meals, milk and school clothes are supplied to pupils. Only about 5% of children attending school in the territory were over fourteen (at the 1961 census) although high schools were established in Darwin and Alice Springs. An apprentices board was set up to encourage theoretical training of apprentices through South Australian and New South Wales technical education correspondence courses.

Health and Welfare.—The Northern Territory medical service, part of the commonwealth department of health, assumes responsibility for medical and dental services and conducts four general hospitals, at Darwin, Alice Springs, Tennant Creek and Katherine. The aerial medical services of the department and the Alice Springs station of the Flying Doctor network provide ambulance and medical services to outlying areas (*see* FLYING DOCTOR SERVICES). Dental clinics are established at Darwin and Alice Springs, and there is also a mobile unit. All medical and dental services are also available to aborigines, and medical aid posts are established at government and mission stations. The government also provides essential services, such as electricity and water supplies, in Darwin, Alice Springs, Tennant Creek and Katherine.

Living Conditions.—The territory is notable for the large amount of land in pastoral occupation and the small number of people employed on these properties. Only about 12% of the nonaboriginal part of the employed population was classed in the 1961 census as employed in primary production, mainly in the grazing industry. More than twice as many aborigines were employed in the pastoral industry and are generally regarded as indispensable to it. Their rates of wages, even for skilled work such as interstate droving, are much below those paid to European workers. Wages for Europeans are rather higher than in the southern and eastern states, the basic wage north of the 20th parallel in the territory being usually about 7%–8% higher. The government has increased its responsibility for housing; this has always

been insufficient and has provided a serious bar to labour immigration into the territory.

The Economy.—*Pastoral Industry.*—The value of production from the pastoral and mining industries (other than uranium) now reaches about the same annual total, each somewhat above £A4,000,000; other products are of much less value. Despite the development of mining, the pastoral industry remains the most stable and important. Except in the Alice Springs area it is almost solely concerned with cattle, exported alive, principally to Queensland (about 60%), South Australia (about 30%) and small numbers to Western Australia and sometimes to Hong Kong and the Philippines. During the 1950s and 1960s the total number of cattle in the territory was above 1,000,000 but with no marked upward trend. Since the early 1950s, when several expert reports on the cattle industry were produced, the commonwealth government has paid more attention to the transport problems of pastoralists and has established more watering facilities on stock routes, built more access roads and increased attention to veterinary services and disease control by means of inspection and isolation and the establishment of treatment areas. Cattle still have to be driven over long distances to reach the railheads or the fattening areas, such as the Channel country of southwestern Queensland. "Road trains," large diesel-motor trucks with long trailers, are gaining in popularity for the transport of fat animals to market, but they damage the unsurfaced roads and are relatively expensive. The only sheep runs in the territory are in the Alice Springs area, but even there numbers declined after the early 1950s—from over 30,000 to half that number by the early 1960s.

Alterations have been made (1954) in the land tenure system aimed at encouraging a large number of smaller holdings, with conditions requiring that greater improvements be carried out. The largest holding is limited to 5,000 sq.mi., and leases up to 50 years may be granted.

Agriculture.—The low rainfall, concentrated in the summer months, the large amount of rocky and stony country and the distance from markets have limited agricultural development. Successful production of vegetables and fruit at several centres for consumption by the forces during World War II and concern about the undeveloped state of the territory led to more intensive surveys of the land resources and experimental work in suitable areas; e.g., at Katherine, chiefly on peanuts, sorghum and a variety of fodder crops; and at Berrimah, near Darwin, on tropical fruit and vegetables. At these and at other places experiments were also carried out with cotton, tobacco and other crops. The most ambitious effort was directed to the growing of rice, both by government stations and also by a private enterprise, with U.S. and some Australian capital, operating about 60 mi. S.E. of Darwin, but this proved commercially unsuccessful.

Mining and Industry.—The discovery of uranium at Rum Jungle, 50 mi. S. of Darwin, in 1949 and the opening of treatment works there in 1954 led to a great increase in the value of mining production. More than half the total value of mineral products (excluding uranium, the value of which is not disclosed) comes from copper, and nearly one-third from gold, Tennant Creek being the most important area for both minerals. Small quantities of manganese, mica (Harts range), tin and silver are also produced. The commonwealth government has assisted the industry, providing treatment plants, crushing and cartage subsidies, roads and water supplies to mining fields, and technical assistance and advice, including the promotion of prospecting. Large deposits of bauxite are known to exist at Wessel Island and Gove peninsula. Secondary industry employs less than 1,000 people and is mainly confined to service industries, building, printing, joinery, repairs, etc., and manufacture of ice cream, aerated (carbonated) waters and beer.

Fisheries.—The fisheries are unimportant; pearl-shell production increased during the 1950s but then seriously declined; a Japanese fleet operates in the area and obtains about three times as much shell, but this is also declining. Japanese shell is not marketed through Australia.

Trade and Finance.—Most of the territory's products are sent to other states, and requirements of manufactured goods, food, etc., come from them. Government expenditure in the 1960s was about six times the revenue collected by the administration under territory ordinances.

Transport and Communications.—Darwin has an international airport, and a number of overseas airlines call there regularly. It is also linked with all the state capitals by several Australian airlines, and the territory has a network of local lines operated by local companies, carrying mail, passengers and freight and subsidized by the commonwealth government. There are more than 100 government or licensed airfields, and the territory is relatively better served by air than by any other form of transport.

Rail transport from Port Augusta in South Australia to Alice Springs improved with the introduction of diesel-electric locomotives in the 1950s, but there is still a gap of 630 mi. in the long-promised north–south railway that begins again at Birdum with a further 317 mi. to Darwin.

The Stuart highway from Alice Springs to Darwin (954 mi.) and the Barkly highway from near Tennant Creek to Mount Isa in Queensland (403 mi.) were built during World War II. They now carry considerable freight to and from the railheads and also many tourists. About 12,000 mi. of other roads, mainly serving the pastoral and mining industries, are gravel or earth and largely unusable during the wet season.

Darwin is the only port in the Northern Territory capable of accommodating large vessels. It is linked by regular shipping services with Australian ports: one with the west coast (the most frequent), one with the east coast and one with Gulf of Carpentaria ports and Thursday Island. Overseas tankers call about ten times a year with petroleum products and a few other overseas vessels arrive at irregular intervals. The dominance of imports over exports (about ten times by weight) has an unfavourable effect on freight costs.

NORTHERN WAR, the war of 1700–21, sometimes called the GREAT NORTHERN WAR, in which Sweden had Denmark-Norway, Saxony-Poland and Russia as principal adversaries, with Prussia and Hanover intervening against Sweden from 1714 onward.

The Anti-Swedish Coalition.—Sweden's expansion had antagonized the neighbouring states: Russia's access to the Baltic was blocked in Karelia, Ingria and Estonia; Denmark-Norway resented the loss of provinces in the Scandinavian peninsula, especially Scania (Skåne), and was also aggrieved by Sweden's alliance with the ducal house of Holstein-Gottorp, which contained Denmark from the south and prevented the Danish crown's reabsorption of ducal Schleswig and Holstein; the German princes disliked Sweden's power in the Holy Roman empire, and Brandenburg in particular coveted Swedish Pomerania; and many magnates of the Polish republic still thought of Swedish Livonia as Polish by right. The death of Charles XI in 1697, when his heir, Charles XII (*q.v.*), was but a boy of 14, became the signal for Denmark-Norway to organize an anti-Swedish coalition.

Christian V of Denmark-Norway and the elector Frederick Augustus I of Saxony, who in 1697 had been elected king of Poland as Augustus II, made an alliance in 1698 for simultaneous attacks on the Holstein-Gottorp possessions, on Scania and on Swedish Livonia; and Christian's successor Frederick IV renewed this alliance in 1699. Augustus' object was to conquer Livonia with Saxon troops and use it as a bargaining factor in dealing with those magnates who opposed his plans for a vigorous, hereditary monarchy in Poland. The two allies solicited Brandenburg's participation in the coalition, but had no immediate success since the elector Frederick was directing his attention to Franco-Austrian competition for his support in the event of war over the Spanish

succession. Tsar Peter the Great of Russia, however, was prepared to divert his expansionist plans from the Black sea to the Baltic. (*See* PETER I.) Grievously disappointed at Austria's decision to bring the war of the Holy League against Turkey to an end, he bound himself by an alliance with Frederick and Augustus, signed in Moscow in 1699, to attack Ingria as soon as he should obtain peace with the sultan. The exiled Livonian nobleman J. R. Patkul (*q.v.*) was active in all the negotiations which led to the coalition.

The European situation favoured an attack on Sweden. France, Austria, Great Britain and the Dutch republic were preoccupied with the Spanish succession issue. Sweden's efforts to get a greater share of the trade in Baltic naval stores antagonized the Maritime Powers (the British and the Dutch), and Swedish neutrality during the War of the Grand Alliance (1689–97) had caused a general distrust. None of the treaties made by the Swedes since Charles XI's death gave the desired guarantees for their own dominions; but by promising in the treaty of The Hague (Jan. 1700) to help the Maritime Powers if France should attack the Low Countries, Sweden obtained confirmation of the Altona guarantee of 1689 for the land and rights of the duke of Holstein-Gottorp—a guarantee felt to be vital to the security of Sweden proper.

The Strength of the Belligerents (1700).—Sweden and the Swedish dominions had a population of 2,500,000—3,000,000; an army of 40,000, which the system of peasant recruitment could easily expand in wartime; 25,000 mercenaries for garrison duties; 24 capital ships and some smaller vessels; and large economic resources in iron, tar and naval stores. But Sweden lacked capital, and had a bureaucracy which disliked innovations. Denmark-Norway, with the royal parts of Schleswig and Holstein, equaled the population of Sweden and had a good mercenary army of 45,000 and a navy of 26 big ships, but was economically weaker. The elector of Saxony had an army with a high European reputation and with military experience gained in the Turkish war; and though the population of Saxony was small, he counted on tapping Polish resources in manpower if need be. Neither Saxony nor Poland possessed economic resources for prolonged hostilities. Russia had a system of government which could readily exploit its immense reserves of men and material. The Russian army, however, was in the process of reorganization and most of its officers were foreigners. The navy was small and was confined to the Black sea.

The Swedish Victories (1700–06).—In 1700 a three-pronged attack was launched on Sweden: in February, Augustus opened hostilities against Riga with a Saxon army; in March, Frederick IV marched into the ducal parts of Schleswig-Holstein; in August, Tsar Peter crossed the frontier of Ingria to besiege Narva. Since the Danes attacked the duke of Holstein-Gottorp's possessions before Sweden proper, Charles XII received help from the guarantors of Altona. Diplomatic efforts were reinforced by the arrival of an Anglo-Dutch squadron in the sound; and then Charles landed on Sjaelland within a few miles of Copenhagen. By the treaty of Traventhal (Aug. 1700) Frederick IV was forced to restore the *status quo* and to leave the anti-Swedish coalition.

Sweden next contemplated a direct attack on Saxony to counter the Saxon invasion of Livonia in the same way as Frederick IV's invasion of the duchies had been checkmated by a Swedish descent on Sjaelland. The unwillingness of the Maritime Powers to risk disturbance in the Holy Roman empire made such a solution politically impracticable, and in Oct. 1700 Charles XII sailed with 10,000 men to Pernau (Parnu), intending to relieve the siege of Riga. At the news of the Swedish landing, however, the Saxons left their positions, enabling Charles to deal first with the Russians at Narva. The victorious attack of Nov. 30 on Tsar Peter's fortified camp of 23,000 men increased Sweden's prestige and removed the Russian threat to the Baltic provinces for some time. In July 1701 the Swedes successfully fought the Saxons for the crossing of the Dvina river and proceeded, on Augustus' withdrawal into Poland, to occupy Courland, a duchy under Polish suzerainty which had served the Saxon elector as a base for his Livonian operations. Charles now adopted the idea of dethroning Augustus and bringing about the election of a Polish-born king—the eldest of the three Sobieski brothers was the obvious candidate—who would ally himself with Sweden against Russia, accepting Polish expansion in the east as compensation for relinquishing Courland to Charles. The Swedish king was thus drawn into a Polish civil war in which there was both a "Saxon" party and a "Swedish" party, but where the majority of magnates strove for neutrality or at least for reduced military operations on Polish soil. Augustus' unscrupulous but clever move in arresting two of the Sobieski brothers on imperial territory (Feb. 1704) rendered Charles XII's task more difficult but he entered Warsaw in May 1702, defeated the Saxons at K[illegible]zow in July of that year, took Thorn (Torun) after a long siege in 1703, procured the election of Stanislaw I Leszczynski as king in July 1704 and signed a Polish-Swedish treaty of alliance and commerce in Nov. 1705.

The Invasion of Saxony (1706).—Augustus was forced to accept Charles XII's Polish settlement by the victory of Gen. Karl Rehnskiöld over the Saxons and their Russian auxiliaries at Fraustadt (Wschowa) in Feb. 1706 and by the invasion of Saxony in September. In the peace of Altranstädt (Sept. 1706) Augustus' plenipotentiaries sacrificed the Polish crown and the Russian alliance, delivered up Patkul and permitted the Swedish army to spend the winter in Saxony. Charles's headquarters now became the centre of diplomatic activities. France and the Maritime Powers each sought his help in the War of the Spanish Succession but as the two sides were fairly evenly matched, the Swedes, according to their traditional "balancing policy," did not feel called upon to intervene. Charles did, however, answer an appeal of the Protestants of Silesia (whose right of worship had been guaranteed by Sweden in 1648) and forced the emperor Joseph I to recognize their right by the treaty of Altranstädt of Sept. 1707. The main concern of Charles was to prepare an invasion of Russia which, it was hoped, would compel Peter to complete restoration of the *status quo*.

Russia had used the years 1702–06 well. St. Petersburg and Kronstadt had been founded in 1703; Narva had been captured in 1704; and when Charles had left for Saxony in 1706 Peter had occupied Courland and moved a large Russian army to Poland in the hope of fighting the battle for Russia on Polish soil.

The Swedes in Russia and the Ukraine (1707–09).—In autumn 1707 Charles XII marched with nearly 40,000 men east-northeastward through the supposedly impenetrable Mazovian woods, thus maneuvering the Russians out of their Polish positions. He reasoned that Peter would be forced to withdraw from the Baltic provinces if the Swedes threatened Russia proper and planned to advance on Moscow in the spring and summer of 1708, after junction with 12,000 men and an enormous supply train under Gen. Adam Lewenhaupt from the Baltic provinces. He hoped to benefit from the unrest in Peter's rear: from Kondrati Bulavin's rising on the Don (1707–08); from the ambitions of the hetman Ivan Mazepa (*q.v.*) for an independent Ukraine; from the hatred of the Crimean Tatars for the Russians; and from the Turkish desire to reconquer Azov. Tsar Peter did concentrate all his forces inside Russia as expected, but gave orders for the devastation of all territory, Russian and non-Russian, along the invasion routes and for the avoidance of pitched battles for as long as possible. The Swedes brilliantly forced one river crossing after another and won a major encounter at Holowczyn (Golovchin, northwest of Mogilev) in July 1708; but in September the king, then only a few miles from Smolensk, was forced to turn toward the Ukraine in search of food. Lewenhaupt, delayed by heavy rain, was intercepted by the Russians at Lesnaya in October before he had made contact with the king: he lost his supply train and only half his army reached Charles. Mazepa came out in favour of the Swedes but a superior Russian intelligence service coupled with political and military countermeasures put Charles XII in a difficult position. Communications between the Ukraine and Poland were interrupted and Stanislaw was tied down in his own kingdom by Russian-inspired troubles.

Poltava.—Swedes and Russians alike suffered terribly in the bitter winter of 1708–09, and the heavy thaw of the spring circumscribed military operations. By May, however, Charles and Mazepa had gained the co-operation of the Zaporozhian Cossacks

and were in diplomatic contact with the Crimean Tatar khan and the sultan. Peter's diplomacy was equal to that of the Swedes at the Porte; and the Russians maneuvered the Swedes into choosing either battle or retreat. Charles meanwhile was disabled by a wounded foot.

On July 8 (new style; June 27, old style), 1709, the Swedes, with 18,000 out of their now total strength of 22,000, attacked the Russian fortified camp of 45,000 near Poltava. The Russians fought well with superior artillery, and when more than 6,000 Swedes had been killed and more than 2,000 taken prisoner Charles agreed to a retreat toward the Dnieper. Russian destruction of the Zaporozhian fleet prevented the whole Swedish and Cossack army from crossing that river. The generals persuaded the king to put himself and Mazepa in safety with a small force, promising that the major part of the army (now reduced to some 15,000) would rejoin him on Tatar or Turkish territory by means of fords across the Vorskla river. But on the morrow of the king's departure (July 11) the demoralized generals capitulated at Perevolochna to a small Russian detachment.

The Period 1709–18.—Charles XII took refuge in Turkish Bessarabia and, when he learned of the surrender at Perevolochna, ordered a new army from Sweden to join him in Poland or Turkey so that he might take advantage of the now growing Turkish fear of Russian power. Charles XII's diplomacy at the Porte helped to bring about four Turkish declarations of war against Peter between 1710 and 1713; but circumstances prevented the Swedes from obeying their king's order speedily, and without a sizable army at his disposal he could not influence Turkish policy decisively. After the catastrophic defeat of Peter on the Pruth river in the summer of 1711, the Turkish negotiators made peace on condition that Russia should surrender Azov and promise not to interfere in Poland, whereas the tsar had expected to be forced to give up all his Swedish conquests, even Ingria.

Charles's dilemma arose from a revival of the anti-Swedish coalition and the European situation. Frederick IV of Denmark–Norway landed with 15,000 men in Scania in autumn 1709; and Russian forces helped to restore Augustus in Poland, overran the Baltic provinces once more and entered Karelia. Sweden's blockade of the Russian-occupied ports strained relations with the Maritime Powers, who also resented Charles's non-accession to the Declaration of Neutrality for the empire (The Hague concert of 1710) arranged by them with Sweden's enemies so as not to lose the hired Danish and Saxon troops vital in the war against France.

In 1712 the Swedes managed to send an army under Gen. Magnus Stenbock to Pomerania, but the Danes destroyed his supply fleet so that he could not proceed to a junction with Charles. Stenbock moved across Mecklenburg toward Holstein, defeating the Danish army at Gadebusch (Dec. 1712), but pursuit by Russian and Saxon, as well as Danish, troops drove him to take refuge in the fortress of Tönning (on the North Sea coast of Holstein), where he capitulated in May 1713. This surrender discredited Charles XII in Turkish eyes. The king had already had to use diplomacy and even force (as in the violent incident of 1713, known as the *Kalabalik*) to resist a Turkish attempt to drive him home via Poland, where he feared capture; now he departed voluntarily, but across Habsburg and imperial territory, to reach Stralsund in Swedish Pomerania in Nov. 1714.

By this time most of Sweden's possessions in the empire were enemy-occupied or threatened. The Danes had moved into Bremen and Verden; most of Pomerania was held by Russian and Saxon troops. Frederick William I of Prussia and George I of England, in his capacity as elector of Hanover, demanded land in return for continued neutrality; and when Charles would offer no more than temporary cession of parts of his German possessions they joined the anti-Swedish coalition. In Dec. 1715, just before Stralsund fell to his enemies, Charles returned to southern Sweden to reorganize his country effectively for a new stage of the war. A subsidy-treaty with France, a diversionary attack on Norway, negotiations with the British Jacobites to weaken George I's position and the issue of passes to Dutch ships against loans followed while Sweden's resources were mobilized and new armies raised. In April 1716 the last Swedish outpost on the German coast, Wismar, fell; but a joint Danish-Hanoverian-Russian descent on Scania, planned for the summer, came to nothing because of mutual jealousies inside the coalition. Charles skilfully exploited these jealousies, and two separate sets of peace negotiations were begun: one with Tsar Peter at a formal congress in the Åland islands, the other with George I more informally via Hessian diplomats.

The building of large magazines of food and the raising of the army to 60,000 men presaged a new military offensive to obtain peace terms that would maintain Sweden's position as a great power. The campaign began in Sept. 1718 when Charles invaded southeastern Norway with 30,000 men, but before the full intentions of the war plan were revealed he was killed at the siege of Frederikshald on Nov. 30 (O.S.).

The Conclusion of the War (1719–21).—As Charles left no children, Sweden had to settle the succession issue. Ulrika Eleanora, his only surviving sister, secured the throne with the help of her husband, Frederick of Hesse (*see* FREDERICK I of Sweden). The disappointed candidate, Charles Frederick of Holstein-Gottorp (the son of Charles XII's elder sister Hedvig), accepted refuge with the Russians, who had overrun all Finland and were raiding the coasts of Sweden. Frederick of Hesse, basing his peace plan on terms with George I in return for help against Peter, negotiated a series of settlements: Sweden ceded Bremen and Verden to Hanover and gave commercial advantages to Great Britain in return for promises of naval and diplomatic help to regain the Baltic provinces (Nov. 1719); gave up Stettin (Szczecin) and Pomerania south of the Peene river to Prussia (Feb. 1720); and, to please Denmark-Norway, renounced the alliance with Holstein-Gottorp and the right to free passage through the Sound (June 1720). The advantages expected in return for these sacrifices never materialized; Great Britain was paralyzed by the South Sea Bubble (*q.v.*), and George I's scheme for a European coalition against Russia evaporated. The Swedes were forced to sue for peace with Peter, and by the treaty of Nystad (Sept. 10, 1721), Ingria, Estonia, Livonia and a strip of Finnish Karelia with Viborg (Viipuri) were ceded to him.

Russia thus emerged as a major power in the Baltic, thanks to skilful leadership and superior resources, but also to the historical accidents of the years 1718 to 1721, not least of which was the survival of Peter. The other original members of the coalition gained little: Augustus had to be content with a Swedish recognition of him as king of Poland in the form of an armistice (Nov. 1719), but never obtained Polish Livonia, despite Russia's promises; Denmark could only incorporate ducal Schleswig under guarantee from England and France and occupy ducal Holstein without formal guarantee. Prussia and Hanover, the late entrants, did well: the former by adroit balancing between the western and eastern members of the coalition; the latter by exploiting the connection with England. For Sweden the German settlement, allowing the retention of Wismar, Pomerania around Stralsund and Rügen, was less galling than the Baltic one: expulsion from the Baltic provinces was humiliating and economically disastrous, and the Swedes long hoped to regain at least Narva or Riga.

See also SWEDEN: *History*. (R. M. HA.)

NORTH HOLLAND, a Netherlands province, lying between the North sea and the Zuider Zee (IJsselmeer) and bounded southward by the provinces of South Holland and Utrecht. Formed in 1840 by the division of Holland into North and South, its present area, including the island of Texel, is 1,124 sq.mi. Pop. (1960) 2,057,322. The island of Marken in the Zuider Zee since 1957 has been connected by embankment with the mainland; the former island of Wieringen, now incorporated with the mainland, is the starting point of the Afsluitdijk, the dike which encloses the Zuider Zee and connects North Holland and Friesland. Four natural regions can be recognized: (1) foreshore and sand dunes, (2) inner dunes and the geest grounds, (3) low fens and clay lands, and (4) the glacial region of the Gooi, in the most southeasterly part of the province.

The sand dunes form a long, smooth, unbroken protection for the other regions, and the lack of inlets explains the absence of industrial towns. However, the broad, gently sloping, sandy beach

is admirable for sea bathing and Zandvoort, Bergen aan Zee. Egmond aan Zee and Wijk aan Zee are gay and unconventional resorts. The fishing port of IJmuiden at the west end of the artificial North Sea canal is also the foreport of Amsterdam and noted for its huge locks. The North Sea canal area has developed into an important industrial district (IJmond). Opposite IJmuiden, blast furnaces connected with steel works, rolling mills and manufacture of fertilizers. have been established. There are paperworks at Velzen, and a chemical plant at Beverwijk. Haarlem (*q.v.*), once the residence of the ancient counts of Holland and an important industrial town since the 17th century, is now the provincial capital and the centre of bulb-trading.

The geest grounds, behind the inner dunes, contain some of Holland's famous bulbfields which stretch north to Haarlem and continue southward into South Holland, where hyacinths, tulips. narcissi and crocuses, in exact squares of brilliant and varied colours, attract numerous tourists each springtime. Aalsmeer (*q.v.*), about 12 mi. S.E. of Haarlem, has the most important flower auction hall in Europe. North of the North Sea canal, market gardening dominates on the geest. Near Haarlem are the extensive red brick ruins of Brederode castle, the seat of an old and illustrious family. To the north are remains of the castle of the counts of Egmond and the church of its famous abbey which has been rebuilt.

The third and by far the largest region lies at or below sea level. The oldest parts consist of peat, but clay predominates in the considerable reclaimed areas. To the north of the former IJ (inlet of the IJsselmeer) the Wormer, Schermer, Purmer and Beemster lakes were drained in the 17th century, but several sea polders to the north of these were not added to the mainland until the first half of the 19th century. Wieringermeer was reclaimed by 1930. This part of the province is traversed by the 46-mi. North Holland canal (1819–25), extending between Amsterdam and Den Helder; the IJ was drained, and the direct east-west 15-mi. North Sea canal was cut in its stead (1865–76). In the south, the Haarlemmermeer polder (110 sq.mi.) was reclaimed between 1840 and 1853. The landscape in this lowland division is typically Dutch (dotted with many windmills and losing to urbanization). Cattle rearing is the main industry. Most of the milk is consumed directly by the urban populations; but some Edam cheese is produced for export. Purmerend is the chief cattle market. Alkmaar (*q.v.*), which originally belonged to the lowland zone, has important historical associations, being the first town that successfully resisted the Spaniards in the Eighty Years' War; it has an ancient weighhouse, and is a marketing centre noted for cheeses. The northern polders, especially the Wieringermeer, are agricultural. Market gardening occurs in several places; cabbages are grown north of Alkmaar and seeds in the eastern part of west Friesland. The security offered by the Zuider Zee for shipping was the prime factor in development of the coastal part of this region, and Medemblik, Enkhuizen, Hoorn, Edam and Monnikendam (now small regional centres) possessed a large foreign commerce in the 16th and 17th centuries. Prosperity was later concentrated upon the IJ (Amsterdam) and the series of industrial settlements situated on its offshoot, the Zaan, of which Zaandam with sawmills, food and paint industries, is the most important.

The fourth region, the Gooi, consists of a glacial ridge, once covered with heath, with small rural villages. By mid-20th century, however, it had grown into a considerable residential and industrial region centred on Bussum and Hilversum (*q.v.*).

Of the islands, Marken tends to commercialize its own quaintness, though it is not yet entirely spoiled. The island of Texel is noted for its sheep and is a modest resort area. The fishing village of Volendam on the mainland has kept its traditional features.

For historical aspects *see* HOLLAND, COUNTY AND PROVINCE OF; NETHERLANDS, THE. (H. J. KE.)

NORTHINGTON, ROBERT HENLEY, 1ST EARL OF (*c.* 1708–1772), lord chancellor of England, was the second son of Anthony Henley, a Whig member of parliament. Robert was educated at Westminster school and St. John's college, Oxford, and was called to the bar in 1732. In 1747 he was elected member of parliament for Bath, of which he became recorder in 1751. In the same year he became a king's counsel. He acquired a lucrative practice at the bar and in 1756 was appointed attorney general. In the following year, he was promoted to the office of lord keeper of the great seal, being the last person so designated. He was given the title of Baron Henley in 1760 so that he could preside as lord high steward at the trial of Earl Ferrers for murder.

He became lord chancellor on the accession of George III in 1761, and in 1764 he was created earl of Northington. He was a member of the group known as "the king's friends," and was instrumental in procuring the dismissal of the marquess of Rockingham and the recall of Pitt to office in 1766. He joined this government as lord president of the council, but was increasingly incapacitated by attacks of the gout. He resigned office in 1767 and died at his home in Hampshire on Jan. 14, 1772.

BIBLIOGRAPHY.—Lord Henley, *Memoir of Robert Henley, Earl of Northington* (1831); Lord Campbell, *The Lives of the Lord Chancellors* (1845–47); E. Foss, *The Judges of England* (1848–64); Horace Walpole, *Memoirs* (1894).

NORTH KAZAKHSTAN OBLAST (SEVERO-KAZAKHSTANSKAYA (OBLAST')), in the Kazakh Soviet Socialist Republic of the U.S.S.R., was established in July 1936. Area 15,869 sq.mi. It is divided into ten *raions* and has one town, the capital, Petropavlovsk (*q.v.*), and three "settlements of town type." After December 1960, it formed part of a newly created region (Tselinnyy *krai*, the Virgin Lands region, abolished in 1965). The *oblast* occupies the southern edge of the West Siberian Lowland (Zapadno-Sibirskaya Nizmennost) and is drained by the Ishim River. The climate is continental, the average January temperature being about −18° C (0° F) and the July average 19° C (66° F). The *oblast* is covered with a number of shallow fresh- and salt-water lakes. The northern part is wooded steppe and the southern, black earth.

The population (34% urban) was 456,999 in 1959, with Russians predominating but also including some Kazakhs, Ukrainians, Tatars, Mordvins, and Germans. There are nearly 600 schools and 8 special-training establishments, and Petropavlovsk has a museum. The economy is mainly agricultural, including the cultivation of wheat, oats, and millet, and dairy processing, as well as livestock breeding. The total sown area is about 5,000,000 ac., of which roughly three-quarters is under grain (mainly wheat) and one-quarter under fodder. There are small areas under vegetables and technical crops (flax and sunflower). The livestock consists mainly of sheep and cattle with a smaller number of pigs, goats, and horses. Industry is mainly concerned with food processing (meat packinghouses, flour mills, canneries).

The *oblast* is traversed by the Trans-Siberian railway with branches running south from Petropavlovsk to Kokchetav and from Bulayevo to Molodogvardeyskaya. It is also crossed by the Tuimazy-Omsk oil pipeline. (G. E. WR.)

NORTH PLATTE RIVER: *see* PLATTE.

NORTH RHINE-WESTPHALIA (NORDRHEIN-WESTFALEN), a *Land* (state) of the Federal Republic of Germany, bordered (south) by the Netherlands, Belgium and the *Länder* of Rhineland-Palatinate and Hesse, and (east) by Lower Saxony. Area 13,119 sq.mi.; its population at the 1961 census was 15,901,678 (including about 2,500,000 refugees), which is nearly 30% of the republic's total and more than one-third of its industrial workers. The *Land*, which has no historic unity, was created in 1946 through the amalgamation of the former Prussian province of Westphalia and the northern portion of the Prussian Rhine province; the state of Lippe was incorporated in 1947. For history of these constituent parts prior to World War II *see* RHINELAND; WESTPHALIA; LIPPE.

Physical Features.—The *Land* includes portions of three main physical divisions of Germany—the northern part of the Rhine plateau, the Weser hill country, and the North German lowland.

The Rhine plateau includes the northern section of the Eifel west of the Rhine, and the Sauerland and the Berg-Mark east of the Rhine. These are rolling plateau areas with a maximum height of 2,625 ft. (800 m.) and consist of impervious slates and sandstones, with a northeast-southwest strike, though areas of lower

and smoother relief with more fertile soils occur on the middle Devonian limestones both east and west of the Rhine. A fertile lowland lies at the confluence of the Moselle and the Rhine.

The Weser hill country is enclosed by two sharp ridges formed by the steeply tilted limestone strata of an eroded anticline, in which a variety of limestones and marls and clays (mainly of Triassic date) form a variegated pattern of local relief within the two inward-facing wooded scarps. At Ibbenbüren a small Carboniferous coalfield is near the surface. Loessic deposits occur in pockets in the area and the highest points reach about 1,640 ft. (500 m.).

The North German lowland comprises the Lower Rhine lowland (below Bonn) and the Münster lowland. The Lower Rhine lowland is formed of deep deposits of Upper Tertiary and glacial sands and gravels that were laid down by the fluvial ancestors of the Meuse and Rhine and cut during interglacial periods into a series of terraces at different levels. West of the Rhine these deposits were faulted and broken into three horsts, running northwest–southeast. The chief of these is the Ville (Vorgebirge) that stretches from the level of the high terrace at the Venusberg in Bonn. Two lesser parallel horsts lie west of the Ville which contains thick beds of lignite (brown coal) that are extensively exploited in vast opencut workings with adjacent briquette and electricity plants. The same beds are exploited in the small ridges to the west; intervening areas are filled with loess. The Münster lowland, plastered with glacial sands and clays, is a syncline developed on Cretaceous rocks. Limestone strata have outward-facing scarps, the chief of which is the Senonian scarp that lies around Münster. The main scarps (Turonian and Cenomanian limestones) form the Teutoburger Wald to the north, while to the south the strata are almost horizontal and form the dry Hellweg loess-covered limestone plateau with a scarp called the Haarstrang overlooking the valleys of the Ruhr and the Möhne.

The Rhine plateau is well drained and in the Eifel, and especially along the Ruhr, dammed lakes have been formed to supply industrial areas with water. The highest parts of the plateau to the south get the heaviest rainfall where it exceeds 40 in. a year. The Northern lowland gets about 28 in. annually and the central part of the Cologne bay, one of the driest areas in Germany, has under 24 in.

The richest soils are on the loess deposits in the Cologne bay, the Hellweg and the patches in the Weser hill country. Sands and clays predominate in the glaciated Northern lowland and thin sandy acidic soils cover most of the Rhine plateau.

Population and Administration.—A large part of North Rhine-Westphalia has been urbanized and one-half of its population lives in cities with more than 100,000 inhabitants. The cities sustained heavy war damage, and by 1945 their populations had been greatly reduced; on the other hand, the people living in the rural districts had substantially increased with the flow of evacuees. However, after 1950, the phenomenal revival of industry and the rapid construction of houses and apartments enabled the cities to grow with remarkable rapidity; most of the rural districts lost their surplus populations and many agricultural workers turned to industry and urban life. The majority of the cities in northwestern Germany now have more inhabitants than they had in 1939. At the 1961 census the population was 43% Protestant and 52% Roman Catholic. Institutions of higher learning include the universities of Cologne, Bonn and Münster, the technical high school of Aachen and the medical academy of Düsseldorf.

The constitution in force in the mid-1960s was approved by the *Landtag* (diet or consultative assembly) on June 6, 1950, and by the electorate on June 18. The *Land* government (*Landesregierung*) is presided over by the minister-president (*Ministerpräsident*) who appoints a cabinet of ministers. At the elections held July 8, 1962, there were 96 Christian Democrats, 90 Social Democrats and 14 Free Democrats returned to the *Landtag*. North Rhine-Westphalia is divided into six major administrative divisions (*see* Table), 38 urban districts and 57 rural districts. The capital is Düsseldorf, and Bonn, the federal capital, is situated in North Rhine-Westphalia.

The Economy.—North Rhine-Westphalia accounts for one-third of the production of electricity in the Federal Republic, virtually all the coal (with the exclusion of the Saar and the brown coal) and more than 90% of the iron and steel; it dominates the industrial economy of the republic to an even greater degree than it did as a part of the third *Reich*. By the mid-1960s more than half of its workers were engaged in industry and building, followed by those in (1) commerce and transport, (2) public and private services and (3) agriculture and fishing. The dominantly agricultural areas are in the lower Rhine bay, Münsterland and the Weser hill country. The main industrial groupings form a great rectangular block, focusing in the west-east belt of the Ruhr industrial region (*Ruhrgebiet*) and the Wuppertal area to the south of it. The corners of this block are defined by the towns of Dinslaken in the northwest, Opladen in the southwest, Hamm in the northeast and Lüdenscheid in the southeast. Attached to this vast complex is the Gladbach-Krefeld area west of the Rhine. Smaller industrial areas in the *Land* are Aachen-Düren (textiles, machinery, coal mining), Cologne-Bonn (with remarkable expansion since World War II in chemical plants and oil refineries on the Rhine and the development of brown coal workings in the Ville), the Siegerland (an old established iron- and steelworking area based on the deep mining of iron ores and imported Ruhr coal), and eastern Westphalia (textiles and machinery). The *Ruhrgebiet* has its main urban centres in Duisburg, Essen and Dortmund and its development is controlled by the *Ruhrsiedlungsverband* (Ruhr development association), established in 1921. This is the main seat of the coal-mining and iron and steel industries in Germany and indeed in the whole of western Europe (*see* RUHR).

Agriculture gives full-time employment to little more than 10% of all workers but about one-third are partly dependent on farming. The chief crops are potatoes, sugar beet, wheat, rye, barley and oats. Holdings of 5–50 ha. comprise 55% of the farming area and these form the real basis of agriculture in the *Land*. They have been consolidated for more than a century in the Cologne bay and the Hellweg, but there is still a need for consolidation of fragmented holdings. There has been much afforestation and the construction of windbreaks in the main cultivated areas is

projected. Less than 20% of the wooded land is classed as coppice, where the tree growth is controlled and cut at regular intervals for the use of the owners.

Communications are dominated by the Ruhr network in which the main direction of routes is west to east, and by the south-north routes across the Rhine plateau, notably along the Rhine. In the Ruhr there are two canals, the Rhine-Herne and the Lippe, that connect the Rhine with the Dortmund-Ems canal. Barges up to 2,500 tons can navigate the Rhine as far as Strasbourg and small oceangoing boats can reach Cologne. The greatest river port in Europe is Duisburg at the western end of the Ruhr industrial area. The *Autobahn* from south Germany parallels the east bank of the Rhine and the main west-east route runs along the north side of the Ruhr urban areas to Bielefeld and Hanover. Other roads include the so-called *Ruhrschnellweg,* which runs west-east through the centre of the urban areas and traverses the centre of Essen by means of an underpass. (R. E. Di.)

NORTHROP, JOHN HOWARD (1891–), U.S. biochemist, winner of the 1946 Nobel prize in chemistry with Wendell M. Stanley and James B. Sumner for pioneering research in the crystallization of enzymes and related substances, was born July 5, 1891, at Yonkers, N.Y. Columbia trained (B.S., 1912; M.A., 1913), he received his Ph.D. in 1915 and studied as Cutting traveling fellow with Jacques Loeb at the Rockefeller Institute for Medical Research on theories of life duration. He became a member of the institute in 1924. In 1949 he was named research professor of bacteriology at the University of California, Berkeley.

Early work by Northrop on fermentation to produce acetone and ethyl alcohol during World War I led to the study of enzymes essential for digestion, respiration and general life processes. He showed that enzymes obey chemical laws. In 1930 Northrop prepared pepsin in pure crystalline form. With Moses Kunitz he succeeded in crystallizing the enzymes trypsin and chymotrypsin as well as their precursors trypsinogen and chymotrypsinogen. With Roger M. Herriott he isolated crystalline pepsinogen. He studied proteins of meat, viruses and antibodies. From the intestines of mammals, Northrop isolated a bacteriophage, a virus which destroys bacteria.

Northrop also made studies on starch, the kinetics of bacteriophage, agglutination of bacteria and temperature effect on insects, and purified diphtheria antitoxin (1941). He published *Crystalline Enzymes* (1939) and edited the *Journal of General Physiology* of the Rockefeller institute. He served in the U.S. army chemical warfare service in World War I as captain, and in World War II he was consultant to the National Defense Research committee.

(V. Bw.)

NORTH SEA (formerly also known as the German Ocean), a sea occupying a shallow basin between Great Britain and continental Europe. It extends southward from the edge of the continental shelf north of the Shetland Islands to the Straits of Dover, covering an area of about 220,000 sq.mi. Its bed generally slopes gently down from south to north. The southernmost areas are very shallow, with many low ridges of sand barely covered at low tide. Off the mouth of the Humber an east-west trench, the Silver Pit, has depths of nearly 50 fathoms in places. The Dogger bank is situated to the north of this trench and occupies about one-third of the width of the sea. Depths over the bank vary from 8 to 20 fathoms and are less than 10 fathoms over 250 sq.mi. of its area. The north face of the bank is steep but thereafter the seabed slopes very gently northward, though cut by several depressions, until the continental edge is reached. In the northeast the Norway deep is a remarkable feature. It starts off Ålesund as a break in the continental slope and extends southeastward as a narrow trench, parallel to the Norwegian coast, into the Skagerrak as far as Oslo. Its depth increases toward its head, depths of about 400 fathoms being recorded in the Skagerrak. Its edge rises very steeply on the Norwegian side, but much more gently on the west.

Geological History.—The main structural features that limit the North sea basin date from the time of the Caledonian and Armorican earth movements, the degree of submergence of the basin varying from geological era to geological era. At the end of the Pliocene period southern England was linked with Holland and Germany by a forested plain which was crossed by the marshy delta of the Rhine-Thames river system. Conditions became steadily colder and during the Pleistocene period the sea was covered by ice sheets which varied in extent during the different glaciations. At the time of the maximum glaciation the whole sea as far south as Holland and East Anglia was covered by ice. Thus there was no northern outlet for the Thames and Rhine systems and it is thought that these rivers drained into a glacial lake south of the ice front in the extreme south of the present North sea basin. The water in this later rose and eventually escaped through a Pliocene river valley which was later to form the Straits of Dover: this valley was greatly widened and deepened by the overflowing water. Toward the end of the Ice Age the North sea south of the Dogger bank became a low-lying plain crossed by meandering rivers. At first this plain had an Arctic climate, but later amelioration led to the afforestation of the area and to the Dogger bank's being occupied by a fen in which peat accumulated. Trawlers fishing on the Dogger have brought up masses of this peat, sometimes containing teeth and bones of animals which roamed the area at that time. After 6000 B.C. the sea level rose and the North sea and Straits of Dover assumed more or less their present form.

Coasts.—The coasts of Norway and Scotland are usually cliffed except along the more penetrating inlets; the cliffs being cut in highly resistant rocks. Farther south the coasts are composed of softer rocks, but cliffs of considerable height are present on the English coast as far as the chalky heights of Flamborough head. South of this point low cliffs of glacial material fronted by sandy beaches are characteristic of the English coast until the North Foreland is reached, when chalk cliffs occur again. The continental shores south of the Skagerrak are usually low and flat and backed by wide marshes and are sometimes protected by sand dunes or artificial dikes.

Temperature and Salinity.—Atlantic water, with a salinity of more than $35^0/_{00}$, enters the North sea through the Straits of Dover and between Shetland and Norway. The two inflows meet in the neighbourhood of a line extending from the Wash to the Skagerrak and give rise thereabouts to a complicated system of eddies. The water entering through the Straits of Dover is diluted on both sides by land drainage particularly from the Thames, Rhine and Elbe systems. The northern oceanic inflow mixes with land water from Scotland and northern England and with water of less than $30^0/_{00}$ which flows out of the Skagerrak northward along the coast of Norway: the low salinity of this latter water is due to its containing much brackish water from the Baltic. In February, the coldest month, the mean maximum sea surface temperature is about 6.5° C. (44° F.) and occurs in the two oceanic inflows. Near the Danish coast the sea freezes in an average winter. In August, the warmest month, the mean maximum surface temperature is 17.5° C. (63° F.) near the Dutch and Danish coasts: the lowest is 12° C. (54° F.) off northeast Scotland.

Tides.—The tides in the North sea are standing oscillations modified by the effects of the earth's gyration. There are two well-defined amphidromic systems, one in the centre of the Southern Bight and one west of Denmark, and a less well-defined system close to the southwest coast of Norway: three tidal oscillations progress round these points each in an anticlockwise direction. As the two northerly points are close to the continental shores the tidal range on those shores is small, less than 5 ft. at spring tides, while that on the English shore is much larger and reaches 20 ft. on the Lincolnshire coast. In the Southern Bight the central position of the amphidromic point results in the tidal range's being the same on the two coasts and to its being large, nearly 16 ft. at spring tides, close to the Straits of Dover, and smaller, about 7 ft., farther north at Yarmouth and Den Helder, Neth.

Fisheries.—The waters of the North sea are fertile because of the large amount of minerals brought into it by rivers and the strong stirring, caused by winds, tidal streams and winter cooling. This stirring ensures that the nutrient salts, upon which the plant plankton, the basis of the food chain in the sea, depends

are kept in good supply in the sunlit surface layers where plant production occurs. The fish depend, through the animal plankton, upon the plant plankton. The total annual catch of fish in the North sea is about 1,600,000 tons. Half of this catch consists of herring, 6% of cod, 6% of haddock, 5% of whiting and 5% of plaice. Intensive exploitation of the fish stocks has led to some of them being overfished. The principal nations sharing the catch are the United Kingdom, the Federal Republic of Germany and Denmark, 18% each, and the Netherlands and Norway, 13% each.

NORTH SHIELDS: *see* TYNEMOUTH.

NORTHUMBERLAND, EARLS AND DUKES OF. This English title derived originally from the kings of Northumbria who became known as earls of Northumbria in the later Saxon period. From their fortress at Bamburgh they ruled the area approximately between the rivers Humber and Tweed. SIWARD (d. 1055) controlled the whole area by 1042. The earldom was then held briefly by TOSTIG (d. 1066) and then by MORCAR whose title was confirmed by William the Conqueror after 1066. Mocar rebelled in 1068 and 1071, joined Hereward in the Isle of Ely and was captured and imprisoned until his death. The earldom was then held from 1071 to 1072 by COSPATRIC and then by WALTHEOF (*q.v.*; d. 1076). The earldom was suppressed in 1095 by William II after the rebellion of ROBERT DE MOWBRAY (d. 1125?), who had been made earl in 1080 or 1081. In the 12th century the earldom was alienated to the kings of Scotland and was held briefly by HENRY (*c.* 1114–1152), the son of David I, and by WILLIAM (1143–1214) afterward William I, the Lion, king of Scotland.

The earldom again became famous when it was granted to the Percy family. HENRY DE PERCY (1341–1408), marshal of England, was created earl of Northumberland at Richard II's coronation in 1377. He served Richard in numerous capacities but after 1398 supported the duke of Hereford (afterward Henry IV) and took a prominent part in Richard's abdication. His son, Sir Henry Percy, known as Hotspur, figures prominently in Shakespeare's *1 Henry IV*. Hotspur was killed at the battle of Shrewsbury (1403) fighting the king, and Northumberland, after being attainted in 1406 for plotting against the king, was slain at Bramham Moor (Feb. 19, 1408). The Percys were Lancastrians and HENRY (1393–1455), 2nd earl and Hotspur's son, was slain at the first battle of St Albans fighting for Henry VI; while HENRY (1421–1461), 3rd earl, fell at the battle of Towton (1461). The earldom was then briefly given to JOHN NEVILLE (*q.v.*; *c.* 1431–1471) but returned to the Percys in 1470 when HENRY (*c.* 1449–1489), son of the 3rd earl, was restored as 4th earl by Edward IV. The 4th earl acquiesced in the accession of Richard III and submitted to Henry VII with whom he found favour. HENRY (1478–1527), 5th earl, known as the Magnificent, was prominent in the early years of Henry VIII. The earldom lapsed in 1537 on the death of HENRY (*c.* 1502–1537), 6th earl, whose brother was attainted for his role in the Pilgrimage of Grace (1536).

JOHN DUDLEY (1502–1553), earl of Warwick, was created duke of Northumberland on Oct. 11, 1551 (*see* NORTHUMBERLAND, JOHN DUDLEY, Duke of).

The earldom was restored to the Percy family in 1557 and continued in the male line until 1670. THOMAS (1528–1572), 7th earl, was beheaded for his part in the northern rebellion (1569) which aimed to release Mary Stuart and give toleration to Roman Catholics. HENRY (*c.* 1532–1585), 8th earl, also suspected of pro-Catholic plotting, was imprisoned in the Tower of London where he was found shot in 1585. ALGERNON (1602–1668), 10th earl, became a peer in his father's lifetime as Baron Percy in 1626. He played an important part in the English Civil War. At the trial in 1641 of his friend the earl of Strafford, he gave evidence which, though favourable on the important point of bringing the Irish army over to England, was on the whole damaging. He took an active part in the attempts to come to terms with the king but also helped to organize the New Model army. In 1645 he was entrusted by parliament with the charge of the royal children. He was opposed to the trial of Charles I and took no part in affairs under the Commonwealth and urged moderation after the Restoration. On the death of his son, JOCELINE (1644–1670), 11th earl, the male line became extinct.

GEORGE FITZROY (1665–1716), the illegitimate son of Charles II and Barbara Castlemaine, duchess of Cleveland, was created earl of Northumberland in 1674 and duke in 1683, but he died in 1716 without legitimate issue.

Elizabeth, daughter of the 11th earl, married Charles Seymour, 6th duke of Somerset. Their son, ALGERNON (1684–1750), was created earl of Northumberland in 1749. On his death the title passed to his son-in-law SIR HUGH SMITHSON (1715–1786), baronet, who took the Percy name and arms on inheriting the title in 1750. He was created duke of Northumberland in 1766. He took a prominent part in politics as a supporter of Lord Bute and was lord lieutenant of Ireland (1763–65) but he is best remembered for his cultivated taste. It was the 1st duke who spent much money on restoring Alnwick castle and in employing Robert Adam to remodel the interior of Sion house, near London. HUGH (1742–1817), 2nd duke, a statesman and soldier, commanded the 5th fusiliers, afterward known as the Northumberland fusiliers. GEORGE (1778–1867), 5th duke, was a cousin and heir male of the 4th duke. The son of the 1st earl of Beverley (a title created in 1790 for the 2nd duke's second son), he inherited the dukedom in 1865. HUGH (1914–), 10th duke, succeeded in 1940.

NORTHUMBERLAND, JOHN DUDLEY, DUKE OF (1502–1553), English politician and soldier who virtually ruled England from 1549 to 1553, was the eldest son of Edmund Dudley by his second wife Elizabeth, daughter of Edward Grey, Viscount Lisle, and co-heiress of her brother John, Viscount Lisle. Edmund Dudley was attainted in 1509 and executed in 1510, but John was restored in blood in 1512. A year or so earlier his mother had married an illegitimate son of Edward IV, Sir Arthur Plantagenet, who in 1523 was created Viscount Lisle in his wife's right. Dudley, after holding various minor posts, became deputy governor of Calais in 1538. After his stepfather's death, he was created Viscount Lisle on March 12, 1542. He became warden of the Scottish marches in Nov. 1542; lord high admiral in Jan. 1543; a privy councilor and knight of the Garter in April, and then served with Edward Seymour, earl of Hertford (*see* SOMERSET, EDWARD SEYMOUR, 1st Duke of), in the invasion of Scotland in 1544. Lisle led the assault upon Boulogne (Sept. 1544) and was given command of the town after its capture and commanded the fleet gathered in the Solent against an attempted French invasion in 1545. At court he supported Hertford and Archbishop Thomas Cranmer against the more conservative Howards and Bishop Stephen Gardiner. When the indiscretions of the young Henry Howard, earl of Surrey, brought the Howards down, he was one of the commissioners who found the earl guilty of treason in Jan. 1547. Lisle was also one of the regency council nominated in Henry VIII's will to govern the country during the minority of Edward VI. But upon Henry's death on Jan. 28, 1547, he acquiesced in Hertford's assumption of the office of protector and the title of duke of Somerset. His own rewards included the earldom of Warwick and the office of lord high chamberlain.

In the new reign the two men at first continued to work together. Warwick contributed greatly to Somerset's victory over the Scots at Pinkie in Sept. 1547 and in 1548–49 showed no sympathy with the intrigues of the protector's brother, Thomas Seymour. When, however, in the summer of 1549 Somerset proved unable or unwilling to deal firmly with the widespread popular unrest that his policies had encouraged or provoked, Warwick took the lead in restoring order. It was his victory at Dussindale (Aug. 27, 1549) that put an end to the most dangerous rebellion, that of Robert Ket in East Anglia. This made him the hero of the propertied classes. Religious reformers and conservatives alike rallied to him and the coalition thus formed effected Somerset's deposition and imprisonment in October. Yet even then the breach was not absolute. For the coalition soon fell apart over religion. War-

wick, greedy for the church's remaining wealth, put himself at the head of the advanced Reforming party and threw over those conservative allies who had helped him into power. But he did not yet feel strong enough to combine their expulsion from office and privy council with the continued proscription of Somerset. So the duke was released (Feb. 1550) and readmitted to the privy council in April. In June 1550 Somerset's daughter Anne was married to Warwick's eldest son John.

But reconciliation did not imply sharing power or altering policy. Warwick never assumed the title of protector or any position of formal superiority over the other councilors. But he gradually filled both council and administration with his creatures, binding them to him with the spoils of church and state. At the same time he won an ascendancy over the boy king's mind and affections by encouraging him to cast off the shackles of royal minority. On these foundations Warwick gradually built up for himself and his faction a virtual monopoly of office and authority. All this inevitably bred opposition; opposition that was embittered by the revolutionary character of his policies. Abroad, he speedily abandoned the Tudor designs upon Scotland and their traditional friendship with the Habsburgs and made an ignominious peace with France in March 1550, selling back Boulogne and withdrawing entirely from Scotland. The capitulation was underlined in July 1551 when Edward VI was pledged to marry, not Mary Stuart, as Henry VIII and Somerset had planned, but Elizabeth, daughter of the king of France. Neglect of the navy and the land defenses only accentuated the country's growing subservience to France.

At home Warwick reversed Somerset's more liberal agrarian policy and firmly repressed those who resisted enclosures. He pressed forward the spoliation of the church as well as its reformation by encouraging foreign Protestants to come in and in 1551 by depriving Gardiner and other bishops whose views on doctrine and church property were insufficiently compliant. His policies were not all unstatesmanlike. He made some effort to begin a reform of the repeatedly debased currency. He stimulated English, particularly London, merchants to seek out new markets to lessen England's dependence upon Habsburg Antwerp. He encouraged the opening of trade to Morocco and secured a charter for the syndicate that, with old Sebastian Cabot's advice, was preparing to seek out northward routes to Cathay. But these first glimmers of maritime expansion could not lighten the general unpopularity of his rule. A parliamentary movement in 1551 for Somerset's restoration forced him to keep the houses from meeting and so to deny himself much needed grants. He sought to strengthen his position by making himself duke of Northumberland; his henchman, the marquess of Dorset, became duke of Suffolk, and lesser rewards were scattered among his humbler followers. Thereupon he had Somerset arrested again in Oct. 1551, tried, and executed on Jan. 22, 1552.

He then plunged deeper than ever into revolutionary courses. In Jan. 1552 parliament authorized a new and distinctly Protestant Book of Common Prayer, backed by an Act of Uniformity imposing severe penalties on any who used or attended other forms of worship. Thus committed to Protestantism, Northumberland could not contemplate the possible accession of the Catholic Mary. Early in 1553 it became obvious that Edward was unlikely to live long. To preserve himself against the future, Northumberland embarked upon the most desperate of all his schemes. He married his son Guildford Dudley to Lady Jane Grey (*q.v.*) in May. In June he persuaded the dying king, not yet 16 years old, to will the crown to Jane and her heirs male, to the exclusion not only of Mary but also of Elizabeth and Jane's own mother, the daughter of Henry VIII's younger sister Mary. To this "devise" over 100 councilors, peers, bishops and others were persuaded to append their signatures on June 21. But Edward had no legal power for such an act; Northumberland was too unpopular even for many Protestants to approve it sincerely; and lack of money had compelled him to disband the mercenary troops that might perhaps have coerced those whom he could not persuade. So, when Edward died on July 6, 1553, Northumberland's supporters melted away within a fortnight. He was able to proclaim Jane queen in London on July 10 and then to ride out with a small force against Mary's adherents in East Anglia. There, however, he soon found himself faced by superior numbers. By July 20 he was himself Mary's prisoner and already on July 19 the councilors in London had proclaimed her queen. In a last bid for pardon he declared himself a Catholic, but on Aug. 22, 1553, on Tower hill he paid for his treason with his life.

NORTHUMBERLAND, JOHN NEVILLE, EARL OF (c. 1431–1471), a leading partisan in the Wars of the Roses, was the son of Richard Neville, earl of Salisbury, and brother of Richard Neville, earl of Warwick, the "kingmaker." He was a ringleader in the conflict between the Nevilles and Percys in 1453, which was the real beginning of the civil war. This rivalry, involving an ambition to control the Scottish march, dominated his career. Despite close personal ties with Henry VI, Neville supported Edward IV and as warden of the east march, beat down the last traces of Lancastrian resistance in 1464, notably at Hedgeley Moor (April) and Hexham (May). For this he was created earl of Northumberland in May 1464. A hesitant man, he held aloof from Warwick's intrigues against Edward IV in the summer of 1470. But the king, suspicious of Neville, restored the earldom of Northumberland to Henry Percy (March 1470), creating Neville marquess of Montagu, a title without lands. Neville joined the rebels, which was the immediate cause of Edward's flight abroad (Oct. 1470), but did not attack him on his landing in Yorkshire in March 1471. However, he finally joined his brother at Coventry and was killed with him at Barnet, April 14, 1471.

See C. L. Scofield, *The Life and Reign of Edward IV*, 2 vol. (1923). (GY. T.)

NORTHUMBERLAND, the northernmost and fifth largest county of England, is bounded south by Durham, west by Cumberland, north by the Scottish counties of Berwickshire and Roxburghshire and east by the North sea. Its geographical area is 2,019 sq.mi. Considerable landscape contrasts exist between the coastal plain, the coalfield and industrial areas of the southeast centred on Newcastle, and the uplands of the west and border.

Physical Geography.—Along the borders with Cumberland and Scotland are the Cheviots, rounded hills rising in a series of plateaus between 1,000 and 2,500 ft., to reach 2,676 ft. in The Cheviot, a dome of granite and volcanic rocks of Devonian age. Round it carboniferous rocks dip north to the Tweed basin and east and south to the coast and the Tyne valley. The fells of the west, grits and impure limestones, are deeply cut by the narrow valleys of the Rede, the North Tyne and their tributaries.

To the east of this upland core, Glendale, the valley of the Breamish-Till rivers, follows the cementstone outcrop and is overlooked to the east by the bold, flat-topped Fell Sandstone escarpment of Rothbury and Chillingham forests. Gritstones and limestones stretch in an arc from the middle Tyne to the coast north of Amble and are traversed by more open valleys which contrast with the deeply cut dales of the North Pennines to the south of the Tyne gap, a broad corridor of under 500 ft. A notable feature is the dolerite intrusion of the Whin Sill, which forms the Farne Islands and Bamburgh Castle rock and carries sections of the Roman wall.

The coastal plain, underlain by limestone in the north and Coal Measures in the south, is largely covered by glacial clays, sands and gravels. Impedence and diversion of rivers during the Ice Age created glacial lakes now infilled by alluvial deposits (e.g., Milfield plain northwest of Wooler) and the lower courses of many rivers, including the Tyne, cut relatively deep valleys through glacial deposits to reach the sea.

In the coastal plain soils vary with the glacial drift; heavy loams and clays, notably in the southeast, light sands and gravels are all found. Upland soils are generally thin and acid, with peat on the more poorly drained surfaces. Alluvial haughs alongside the streams of upland valleys provide important stretches of deeper soil.

The county's northerly position and its altitude and exposure to

easterly winds make for a cool climate. Winter is hard, with snow lying for up to 40 days per year on the higher ground. Spring is late, and cool easterly winds, often bringing sea fogs, keep down temperatures on the coast. The highest summer temperatures rarely exceed 15.5° C. (60° F.). However, the climate is relatively dry, most areas below 400 ft. having less than 30 in. of rain per annum (as little as 25 in. on the coast) rising to 50 in. in the Cheviots.

Original woodland was cleared early. Heather moor now characterizes the drier uplands, with *Molinia* grass and cotton-grass moor on peat; on less acid soils *Nardus* gives useful grazing. Since 1926 considerable upland afforestation has been carried out by the Forestry commission, notably in Kielder (north of Tynedale beyond Falstone), Wark and Redesdale forests. There are nearly 100,000 ac. under trees, mainly Norway and Sitka spruce, some Scots and Lodgepole pine and Japanese larch.

The indigenous red deer is extinct, but roe deer are common; wild goats are found in the Cheviots and there is a herd of wild white cattle in Chillingham park (near Wooler). The county is rich in bird life, heather uplands providing grouse and a variety of birds of prey and the coastal areas many waders and seabirds, especially on the bird sanctuary of the Farne Islands (also a breeding ground of the Atlantic gray seal).

The Northumberland National park has 398 sq.mi. of fell (including the Cheviots), while a further 126,000 ac. in Kielder, Wark and Redesdale forests form most of the Border National Forest park. A further 70 sq.mi. of the coast (including the National trust bird sanctuary on the Farne Islands) are classed as an area of outstanding beauty. The National trust owns 14,282 ac. (1961) in the county. (Ri. L.)

History.—In the Neolithic Age, settlements existed in the lower levels of the limestone area running northeast from Hexham to Alnwick. The evidence of beaker pottery suggests that migrants from across the North sea settled at the beginning of the Iron Age. The Roman hold on Northumberland dates from A.D. 122 when the emperor Hadrian built a wall from the Tyne to Solway firth. In 547 Ida laid the foundations of the kingdom of Bernicia, which later extended from the Tyne to the Forth, by building the fortress of Bamburgh which became the seat of the Saxon kings. His grandson, Aethelfrith the Destroyer, established the predominance of the Angles in 603 by defeating the combined forces of Strathclyde Britons and Scots at Degsastan and in 605 annexed the neighbouring kingdom of Deira. Henceforth the region between the Forth and the Humber was known as Northumbria (*q.v.*) and for about 80 years its kings were the most powerful rulers of the Anglo-Saxon states. Lindisfarne, the modern Holy Island (*q.v.*), was the centre for the spread of Christianity throughout this kingdom.

The north was ruthlessly harrowed by William the Conqueror but the Normans later refounded Lindisfarne, Tynemouth and Hexham and established new monasteries, while they built castles which protected the county against invasion from Scotland or over the North sea. The county is not mentioned in Domesday Book, but the account of its revenues appears in the Pipe or Great Roll of the exchequer in 1131. From this period the county palatine of Durham included large parts of Northumberland and the bishops of Durham exercised great influence. These detached parts of the county, called "North Durham," and other separate franchises, were gradually returned to Northumberland.

The county assizes have been held in Newcastle upon Tyne since 1140. From 1843 they have been held there jointly with those of the city of Newcastle. The shire court was statutorily established at Alnwick in 1549. The first reference to the division of the county into wards is in the Hundred Roll of 1295. Two members sat for Northumberland in the parliament of 1290 while in 1295 Bamburgh, Corbridge and Newcastle each returned two. In 1882 Northumberland (originally included in the diocese of Durham) became a separate diocese with the see at Newcastle.

Its political history until the union of the English and Scottish crowns in 1603 is largely a record of border warfare. It was invaded by the Scots in the 12th century and before the battles of Bannockburn (1314), Halidon Hill (1333), Otterburn (sometimes called Chevy Chase after the ballad; 1388), during the Wars of the Roses and before the battle of Flodden (1513). In 1569 the Catholic north rose in support of Mary queen of Scots and Newcastle was captured by the Scots in 1644.

Ancient monuments of the county include castles at Bamburgh, Warkworth (*qq.v.*), Dunstanburgh and Norham; Warkworth hermitage, Lindisfarne priory, Elizabethan ramparts at Berwick-upon-Tweed and the Roman station at Corstopitum, ½ mi. W. of Corbridge. Other castles are at Alnwick, Morpeth (*qq.v.*), Prudhoe, Ford, Chillingham, Langley, Wark-on-Tyne and Newcastle upon Tyne. There are abbeys at Alnwick, Brinkburn, Hulne (the first English Carmelite priory), Blanchland, Newminster and Tynemouth. The priory church at Hexham (*q.v.*) is the oldest in Northumberland. The most impressive stretch of the Roman wall still standing is on either side of Housesteads (Borcovicium). At Chester are the remains of a Roman fort (Cilurnum) and an important collection of Roman antiquities. (*See* also HADRIAN'S WALL.)

Population and Administration.—The population of the administrative county (1,944 sq.mi.) in 1961 was 479,487. The larger towns are situated in the southern and eastern third of the county, which contains in addition, especially near industrial Tyneside, tracts of urban settlement based on large industrial and mining villages, interspersed with agricultural land. The remainder of the county is largely depopulated, and consists of rough fells and difficult uplands, served by the small country market towns of Wooler, Rothbury and Bellingham.

Tyneside was particularly affected by the depression of the 1930s and was included in the "special area" over which a commissioner was appointed by act of parliament in 1934. There are 2 county boroughs, Newcastle upon Tyne (pop. 1961, 269,678) and Tynemouth, including North Shields (70,091); 5 municipal boroughs, including Berwick-upon-Tweed (12,178), a historic county of itself; 11 urban districts; 10 rural districts and 154 parish councils. For parliamentary purposes Tynemouth, Wallsend, Newcastle upon Tyne (four members) and Blyth are constituencies outside the three county divisions which each return one member. The county is in the northeastern circuit and assizes are held at Newcastle. There is a court of quarter sessions for the county at Newcastle and a separate court for the city of Newcastle, and there are 14 petty sessional divisions. The county boroughs and Morpeth have their own police forces.

The Economy.—The county is famous for its wild and exposed scenery, and in earlier times was prosperous from its wool production. Exports in the middle ages were chiefly wool and hides. About half the total acreage of the county is mountain and rough hill pasture, 45% is medium quality land and 5% is good quality. Crops and grass, excluding rough grazings, cover about half the county, oats and barley being the chief crops. There are roughly 4½ times as many sheep as cattle.

The most important mineral resource is coal. It was mined in Roman times and the coal trade of the Tyne developed rapidly from the 13th century. Shipbuilding grew up there as a consequence, and in the early 19th century new investment and inventions, including the steam turbine, created the great shipbuilding and ship-repairing works which now dominate the economy. Iron shipbuilding developed in the 1830s and encouraged local iron foundries, though these have now largely migrated to County Durham. Iron had been smelted in the 13th century, but the lack of heavy timber in the county prevented much development. Other industries that depended on coal took its place: salt panning at the river mouths, particularly at Warkworth, Blyth and North Shields (this industry created in the 17th and 18th centuries a smoke nuisance that has marked its older buildings); and glassmaking, introduced to Tyneside in the reign of James I from German Lorraine. For about a century the Tyneside chemical industries were among the most important of the country but, like the glassworks, failed to maintain themselves. Of industries not dependent on coal, tweed weaving is the most important, being worked originally by hand or by water power; mills may be found on the banks of the Rede and the Wansbeck. Salmon fisheries, particularly in the Tyne and the Tweed, have flourished from the time of Henry I;

there are inshore fisheries based on North Shields. Lead, silver and iron were mined in Allendale and elsewhere from the 12th to the late 19th centuries; stone and brick-clay quarrying has left marks on the countryside throughout. Modern industries, concentrated on the Tyne and Blyth rivers, also include the manufacture of heavy electrical machinery, pottery and soap.

The two principal roads are the Great North road and the west road from Newcastle to Carlisle. The industrial and urban area of the southeast has a network of roads and is also served by local electric railways. The main London to Edinburgh (North Eastern region) railway runs through Newcastle and Berwick-upon-Tweed, and a main line runs west from Newcastle to Carlisle. The principal harbour facilities are those of the Tyne and port of Newcastle. There are passenger services to the Baltic and Scandinavia. There are harbours at Blyth (coal trade) and, less importantly, at Amble and Berwick. The regional airport at Woolsington (Newcastle) operates regular air services to main towns in the British Isles.

(Mi. G. C.)

NORTHUMBRIA was one of the most important of the Anglo-Saxon kingdoms, reaching at its greatest extent from the rivers Humber and Ribble or Mersey to the Firth of Forth and the Ayrshire coast. Its name is derived from Old English *Norþanhymbre* which in a Latinized form was used by Bede to signify all those people of English race who lived to the north of the Humber. The kingdom emerged from the coalescence of two originally independent states, Bernicia to the north and Deira to the south, with the boundary between them marked during the lifetime of Bede by the river Tees. The inhabitants of these two states were known in Old English as Bernice and Dere, names which seem ultimately to be of Welsh rather than English origin. The nucleus of Deira (*q.v.*) lay in the east riding of Yorkshire where many pagan burials have yielded objects indicating that the earliest English settlements took place there long before the time of its earliest recorded king, Aelli (*q.v.*), who was reigning in the second half of the 6th century. The kingdom of Bernicia (*q.v.*) was in origin no more than a pirate settlement established by Ida on the rock of Bamburgh in 547, and so it remained for about 50 years during the reigns of the next six rulers, one of whom, Theodoric, is said to have been besieged in Lindisfarne by a Welsh army led by Urien, king of Rheged.

A rapid expansion occurred during the reign (593–616) of Aethelfrith (*q.v.*), of whom Bede said that he conquered more British territory than any other English king. In 603 he defeated Aidan (Aedan), ruler of the Scottish kingdom of Dalriada, at an unidentified place called Degsastan. Shortly after this he won possession of Deira, thereby creating the kingdom of Northumbria, and he also led a raid deep into Welsh territory to win another victory near Chester.

In 616, however, Aethelfrith was killed in a battle fought near the river Idle against Raedwald of East Anglia, who was supporting Edwin (*q.v.*), the representative of the Deiran dynasty. On the eve of Easter 627 Edwin was baptized at York and so became the first Christian king of Northumbria. He was active in warfare against the Welsh, conquering the kingdom of Elmet (a territory corresponding with part of the West Riding of modern Yorkshire), besieging Cadwallon, king of Gwynedd, in the island of Priestholm off the coast of Anglesey and laying both Man and Anglesey under tribute, but in 632 Edwin was himself defeated and slain by Cadwallon in Hatfield Chase. Northumbria fell apart momentarily but in 633 Oswald (*see* Oswald, Saint) restored the Bernician dynasty by overthrowing Cadwallon in a battle fought near the Roman wall. During Edwin's reign the Bernician royal family had sought refuge among the Picts and Scots and several of them, including Oswald, were converted there. Shortly after his restoration Oswald invited Scottish monks to Northumbria and monasteries were established at Lindisfarne and elsewhere.

Northumbria continued to expand rapidly toward the north during the reign (633–641) of Oswald and of his successor Oswiu (*q.v.* 641–670) and it is probable that Northumbrian rule had reached the Forth shortly before 640. Abercorn became the seat of a Northumbrian bishopric about 680 and Dunbar the seat of an English earl at about the same date. Before the accession of Egfrith (*q.v.*) in 670 the Northumbrians had imposed their rule on Pictish territories between the Forth and the Tay, but in 685 Egfrith, after leading an army across the Tay, was defeated and killed in a battle fought at a place called Nechtanesmere near Forfar. After this defeat the Northumbrian frontier fell back to the Forth where it remained until mid-9th century. The rate of Northumbrian expansion toward the western sea between Clyde and Mersey is difficult to determine. In 750 Eadberht, king of Northumbria, added parts of Ayrshire to his kingdom but it is probable that possession of these lands soon reverted to the British kingdom of Strathclyde whose capital lay at Dumbarton. A Northumbrian bishopric was established at Whithorn in Wigtownshire shortly before 731 and Carlisle may have been reached as much as 100 years earlier.

In Lancashire, estates adjacent to the Ribble formed part of the endowments of the church at Ripon soon after the middle of the 7th century. Northumbria's southern boundary was marked by the Humber on the east and the Ribble or the Mersey on the west. In its central sector it lay roughly along the line of the existing boundary between Yorkshire and Derbyshire. South of this border lay the kingdom of Mercia which became a formidable power during the reign of Penda (d. 654). On several occasions Penda invaded Northumbria, once penetrating as far north as Bamburgh, and it was at the hands of Penda that Oswald met his death in 641. At times during Penda's reign the southern part of Northumbria became a dependency of Mercia, but in 654 a Mercian army, supported by contingents from East Anglia and Wales, was defeated by Oswiu in a battle fought near an unidentified river called Winwaed and Penda was killed. Northumbria's military strength was at its greatest in the 7th century during which the supremacy of three of its rulers, Edwin, Oswald and Oswiu, was recognized by the southern English kingdoms as well as in Northumbria. In later years the power of the monarchy was greatly weakened by internal disorders and many of the 8th- and 9th-century kings had short reigns and met violent deaths.

In the century which followed the death (685) of Egfrith the importance of Northumbria was less in matters political and military than in the intellectual and artistic achievements of what has been called a golden age. The twin monasteries at Wearmouth and Jarrow achieved pre-eminence in the intellectual life not only of England but also of western Europe as a whole. It was at Jarrow that Bede wrote the *Historia ecclesiastica gentis Anglorum* (*Ecclesiastical History of the English Nation*), the supreme example of his own historical and scholarly genius and itself to be accounted among the great literary monuments of the European middle ages. The library at Jarrow was probably matched by libraries of similar quality at Hexham, Whitby and Lindisfarne. Almost all of their contents were destroyed during the Danish invasions but there still survives from Lindisfarne the famous Gospel book which was written and illuminated in about 700 by Eadfrith, bishop of Lindisfarne, and which in its kind is no less a work of genius than Bede's *History*. This book, now known as the Lindisfarne Gospels, remains one of the greatest treasures of the British museum. The skill of Northumbrian sculptors in this age is represented by the stone crosses which are still to be seen at Bewcastle and Ruthwell as well as by many sculptured fragments of comparable beauty.

The intellectual and artistic achievements which characterize the age of Bede could not have been brought to completion without the conditions provided by monastic life, yet it was in part the overgrowth of monasticism which led to a weakening of Northumbria's political power. The transfer of lands to the church made it difficult for the nobility to provide adequately for their sons and many spurious monasteries were founded in which noblemen and officers of government lived with their wives and families, thereby

avoiding the burdens of taxation and military service which would otherwise have fallen upon them. Bede foresaw that if this process were allowed to continue the military strength of the kingdom would not be great enough to enable it to defend itself, and so it proved when the great Danish army which had landed in East Anglia in 865 advanced upon York in the following year. The capture of York by the Danes was the first episode in a process which lasted for two centuries and which reduced the extent of the kingdom to the size of the modern county of Northumberland. After campaigning in different parts of the country for nine years a large part of the Danish army, led by Healfdene, settled down to permanent homes in an area corresponding broadly with the modern Yorkshire. English kings continued to reign at Bamburgh but they were of no importance politically. In the early years of the 10th century Northumbria's southwestern quarter, from the Solway to the Mersey, came under attack from Scandinavian invaders, approaching from Ireland and the Isle of Man. Entering the estuaries of the Dee and the Mersey, they established themselves not only in Lancashire, but also in Westmorland and Cumberland and along the northern shores of the Solway firth. Some of these newcomers sought to win control of the Danish settlements in Yorkshire and during the first half of the 10th century a succession of Norse kings ruled in York. Meanwhile, farther north, the amalgamation in about 850 of the formerly independent kingdoms of the Picts and the Scots created the kingdom of Scotland which began to exert pressure toward the south. In this way Lothian was gradually absorbed into Scotland.

The Tweed first came to be formally recognized as the boundary between Northumbria and Scotland about 975 and there were times when it seemed likely to be pushed farther south to the Tyne or even the Tees. The situation in the northwest at this time is very obscure but it seems probable that the rulers of the kingdom of Strathclyde took advantage of Northumbria's greatly weakened position to push their frontier south to Carlisle and perhaps farther.

The dismemberment of the kingdom of Northumbria was accompanied by changes of a different kind in the midlands and south where a succession of great West Saxon kings—Alfred, Edward the Elder and Aethelstan—not only consolidated their position south of the Thames but also, by absorbing the once independent states of the midlands, brought the kingdom of England into existence. At a gathering at Bakewell in Derbyshire in 920 Edward the Elder received the submission of all the people of Northumbria, whether English, Danes, Norsemen or others. The supremacy of his successor, Aethelstan, was recognized at a similar gathering held in 927 at Eamont, near Penrith. In 934 Aethelstan invaded Scotland and in 937, at an unidentified place called Brunanburh, he defeated a coalition of Scots, British and Norsemen. After Aethelstan's death in 939 the Norsemen regained control of York for a short time, but his successor Edmund later made good the loss (944) and with the expulsion of Eric Bloodaxe from York in 954 the line of Scandinavian rulers there came to an end. From this date there ceased to be any independent kings in Northumbria, which then became an earldom within the kingdom of England. During the 11th century it was held successively by Eric of Norway, by Siward who stoutly defended it till his death in 1055 and by Tostig, one of the sons of Godwin, earl of Wessex. In 1065 the Northumbrians rebelled against the rule of Tostig and he was replaced by Morcar, brother of Edwin, earl of Mercia, but in 1066 Tostig returned, entering the Humber with a large fleet commanded by Harald Hardraade, king of Norway. The invaders were engaged by Edwin and Morcar who were defeated after a hard battle. A few days later Harold II, king of England, arrived from the south and in a battle fought at Stamford Bridge, about three weeks before the Norman victory at Hastings, Tostig and Harald Hardraade were both killed and their army routed

NORTH-WESTERN PROVINCE, CEYLON, covers 3,016 sq.mi. of mainly lowland country stretching inland from the west coast to the foothills of the central highlands. Pop. (1960 est.) 1,086,000. Its coast consists largely of lagoons behind sandbars and spits. Inland the country becomes higher and more rolling but nowhere is there strong relief, except for the hills on the southeastern margin of the province and for isolated summits and ranges like those that give so much character to the provincial capital, Kurunegala (*q.v.*). The province is for the most part underlain by ancient crystalline rocks, but Miocene sediments outcrop in the north. The climate is varied: along the southern border wet zone conditions prevail, then in an east-west belt through Kurunegala the climate is transitional, till, roughly north of the Deduru Oya (river), true dry zone conditions set in, with their characteristic alternation of a rainy season (November to January) and a marked drought (May to September). Rainfall decreases northward, and north of Puttalam is under 50 in. annually. (*See* CEYLON: *Physical Geography*.) The former rain forests of the wet zone part of the province have largely disappeared, but dry zone tropophilous forest (of plants adapted to alternating wet and dry conditions) still covers large areas; it degenerates into thorn scrub in the more arid north. The province includes part of the Wilpattu National park, where a variety of wildlife may be seen.

The inland dry zone part of the province shared in ancient times the civilization based on Anuradhapura (*q.v.*), and a fair number of ruins, inscriptions and irrigation works remain; but there seems to have been relatively little ancient settlement nearer the coast. During the Polonnaruwa (*q.v.*) period in the 8th century A.D. certain sites in the district were used as rock fortresses (*e.g.*, Yapahuwa, near the modern Maho junction) and later, as the old centres became insecure, places like Dambadeniya (just north of the Maha Oya) and Kurunegala were for a time the seats of kings. In Kandyan times Puttalam was used as a port by the Sinhalese kingdom. (*See* also CEYLON: *History*.) The wet zone part grows rice and coconuts; the latter also extend in a belt up the coast as far as Puttalam. In dry zone regions villagers grow rice by irrigation, and there are several recently restored major irrigation works. A branch railway extends up the coast to Chilaw, and the main northern line runs through Kurunegala and the eastern part of the province. There is a reasonably good road network, though no main road runs up the coast north of Puttalam.

The province has a mixed population. In many places Kandyan Sinhalese predominate, but in parts of Puttalam district there are more Ceylon Tamils and Moors (Muslims) than Sinhalese, while in Chilaw district there is a heavy preponderance of Low Country Sinhalese. The population is very unevenly distributed, a high density in Chilaw district and in southern Kurunegala district grading to a very low density in the far north of the province.

NORTHWESTERN UNIVERSITY, a privately controlled, coeducational institution of higher learning, established in 1851 through a charter from the Illinois general assembly. The university maintains two campuses on the shores of Lake Michigan: one in the Chicago suburb of Evanston and the other on Chicago's near north side. *See* EVANSTON.

NORTHWEST FRONTIER, the belt of mountain country constituting the frontier in the northwest of West Pakistan and east of Afghanistan. These borderlands known as the frontier regions, or more commonly as the tribal areas, extend in the north to Chitral as far as the Hindu Kush (*q.v.*) mountains, and in the south as far as Baluchistan (*q.v.*). Between 1901 and 1955 there existed a separate province, the North-West Frontier province, which comprised not only the frontier regions but also six settled districts farther east: Peshawar, Mardan, Kohat, Bannu, Dera Ismail Khan and Hazara. The province was amalgamated with West Pakistan in 1955.

Chitral (*q.v.*), the most northerly of the tribal areas, is a region of deep valleys and lofty ranges, of snow-covered mountains and rich pine forests, though some of the hills are dry and bare. To its south lie the thickly wooded hills of Dir (*q.v.*) and Bajaur and the fertile valleys of the Panjkora and Swat rivers. The Hindu Raj range in the west of Bajaur and Dir, flanked by the Kunar

river on the west, runs northeast and merges by a curving line of hills into the Hindu Kush. The old route eastward from Kabul was through the Kunar valley and the Malakand pass. The Safed Koh range, running east from Afghanistan, forms the divide between the basins of the Kabul and the Kurram rivers and constitutes the Khyber hilly tract, with its historic Khyber pass (*q.v.*) leading from Jamrud Fort to Dakka in Afghanistan. The Kurram valley provides a route to both Kabul and Ghazni beyond Parachinar through the Peiwar Kotal (pass) (8,531 ft.) on the Durand line (*see* below) and through the Shutargardan pass (11,900 ft.) on the spurs of the Safed Koh beyond it. Parachinar is connected by road with Thal (to the southeast) and beyond it by rail with Kohat. Farther south between the Kurram and the Gumal rivers lies Waziristan (*q.v.*), the core of which is a mass of mountains about 11,000 ft. high. The hills are mostly barren and treeless except for pine forests on some of the higher ranges. There are *kachis* or patches of fertile alluvium in the saucers of the Wana plateau to the south. The route from Ghazni along the Tochi valley runs through north Waziristan. It was along this route (according to local tradition) that Mahmud of Ghazni occasionally swept down, when Multan and Sind rather than Peshawar and the Punjab were his immediate objectives. The Gumal pass (*q.v.*) provides an easy route between Ghazni and Tank. It was formerly much frequented by the Powindahs (traveling Pathan merchants). The Afghan frontier crosses the Gumal river at Domandi.

The tribal areas of West Pakistan are separated from Afghanistan by the Durand line, named after Sir Mortimer Durand under whose guidance it was demarcated in 1893. The line extends about 1,400 mi. from north Gilgit (*q.v.*), where the Himalayas and the Hindu Kush meet, to Kuh-i-Malik Siah near the meeting point of the boundaries of Afghanistan, Iran and Pakistan. Its northern portion of about 350 mi. from Gilgit to Bajaur runs along the crest of almost impassable mountains, offshoots of the Hindu Kush and the Himalayas. The southern portion of about 350 mi. from Nushki to the Malik Siah is a desert of deep sand and barren hills where drinking water is scarce and there are no means of communication. The middle section, of 700 mi. between Bajaur and Nushki, crosses mountains 6,000–11,000 ft. in height and is traversed by several important passes including the Khyber, Gumal and Bolan-Khojak. It has long been the keystone of the defense of the frontier.

For administration the tribal areas are divided into six political agencies: Malakand (*q.v.*) including Dir; Swat and Chitral; Mohmand; Khyber; Kurram; and Waziristan, North and South. There are also tribal (now called Special) areas adjoining the settled districts of Hazara, Mardan, Peshawar, Kohat, Bannu and Dera Ismail Khan. For tribal areas outside the agencies, the deputy commissioner of the adjoining district acts as the political agent. Each agency, except the Mohmand, has its own military organization, known as Scouts, commanded by officers of the Pakistan army. These organizations carry out police as well as military functions. The states of Dir, Swat and Chitral have small armies of their own. The national and provincial laws of West Pakistan do not apply to the tribal areas. Except for Chitral, Dir and Swat the frontier regions have a form of democratic government. The administration of justice and the solution of local problems are the concern of elected tribal *jirgas* (councils of elders). (*See* also PATHAN.)

Population.—The 1961 census of Pakistan gave the population of the frontier regions of West Pakistan as 3,260,369 in an area of 22,598 sq.mi. The settled adjoining districts of Peshawar and Dera Ismail Khan divisions, into which the old frontier province was divided, had a population of 4,317,817 and an area of 16,685 sq.mi. The frontier regions are inhabited predominantly by tribesmen, followers of Islam, known variously as Pathans, Pakhtuns (Pashtuns or Pukhtuns) and Afghans. While the tribesmen most often call themselves Pakhtuns, the word Pathan is generally applied to those living in Pakistan; "Afghan" has come to have a connotation of nationality, usually implying those living in Afghanistan. The Pathans are known for their physique, fighting qualities, bravery, hospitality and indomitable spirit of independence. They speak Pashto (*q.v.*), or Pushto, closely related to Persian. Their most important tribes are the Yusufzais of the Malakand agency; Afridis of the Khyber agency and of the Kohat pass; the Orakzais, the Turis and Zaimukht of the Kurram agency; the Wazirs of Waziristan and their kinsmen the Mahsuds of South Waziristan, the Daurs of North Waziristan; and the Bhittanis and Shiranis of the Dera Ismail Khan border. In Chitral the unwarlike Kho, with central Asian rather than Pathan affinities, are the dominant tribe. Their language Khowar (Chitrali) is a Dardic tongue. An ancient people, the Kafirs, live in remote villages. (*See* NURISTAN.)

In the adjoining settled districts, the chief tribes are the Yusufzais of Mardan; the Khalils; Mohmands; Muhammadzais; Daudzais; Gigianis and Khattaks of Peshawar; the Khattak and Bangash of Kohat; the Marwats, Bannuchis and Wazirs of Bannu; and the Gandapurs, Kundis and Mian Khels of Dera Ismail Khan district. There are other minor tribes such as the Jaduns of Hazara and Swabi and the Shinwaris and Mullagoris of Khyber. The strongest in number are the Yusufzais, followed by the Khattaks and Marwats. The Afridis, the Mahsuds and the Wazirs are known as guerrilla fighters while the Yusufzais and Khattaks are noted for their fine physique and martial qualities. Next to the Pathans the numerically strongest people are the Awans. Like the Pathans they are agriculturists, and are scattered over the whole area

Every frontier village has a separate quarter called *kandi* inhabited by one clan called Khel. Each *kandi* has its own chief (*malik*) whose duties are the settlement of disputes, the equitable distribution of crops, etc., and each has its own *jamaet* (mosque), *hujra* (assembly hall) and *burj* (watchtower). The *hujra* serves as public room, court, guest house and social and literary club. Green tea without milk is the common drink. Although Pathans are mildly contemptuous of dancing there are characteristic Pathan dances such as the whirling Khattak dance and the *mashal* (torch dance, which provide splendid physical exercise.

History.—The earliest history of the region is mainly connected with the ancient kingdom of Gandhara (*q.v.*) which included the Peshawar valley and part of the Kabul river valley. In the 6th century B.C. these lands became part of the Persian empire. Later they were successively held in part by the Greeks, by the Mauryan kings of India, by the Indo-Bactrian kings, the Sakas, the Parthians (Pahlavas) and the Kushans (*see* YÜEH-CHIH). The Arabs began incursions into the area in the 7th century, but it was the Turks who established Muslim hegemony there. Subuktigin was the first ruler to extend Muslim rule up to Peshawar. His son Mahmud of Ghazni invaded India from the northwest many times during A.D. 1000–30. With the rise of the Ghoris the frontier territories changed hands again, and Shahab ud-Din Ghori pushed far into the Punjab and established Turkish rule there. A regular stream of immigration of Pathan tribesmen into these regions from Afghanistan continued up to the 18th century. After the decline of the Ghoris, the frontier was successively held by Muslim Afghan dynasties, the Moguls and the Afghan Durranis, ruling either from Kabul or from Delhi. The invasion in 1738 of Nadir Shah of Persia is a landmark in the history of the frontier. From his death to the rise of the Sikh king Ranjit Singh, the frontier districts remained an appanage of the Durrani kingdom. Little control was exercised by Kabul, however, and the country was administered by local chiefs or Afghan sirdars. The Sikh invasions began in 1818. After the second Sikh War, by the proclamation of March 29 1849 the frontier districts were annexed by the British. Later the settled districts were included in the Punjab, while the independent tribes were controlled at different times by the Punjab government and the government of India.

In 1901, the frontier regions with the six settled districts were constituted into a separate province, the North-West Frontier province, under a chief commissioner. It was given provincial autonomy along with the other provinces of India by the Government of India act of 1935. In July 1947, at the partition of the subcontinent, a referendum was held, and the people of the province including those of the tribal belt elected to join Pakistan

After independence propaganda was carried on in the frontier area by Afghanistan for an independent Pathan state variously called Pakhtunistan or Pathanistan which would comprise the whole of the old North-West Frontier province including the set-

tled districts. In July 1949 the Afghan national assembly repudiated its treaties with Britain, regarding the tribal territory, specifically disavowing the Durand line as an international boundary. Afghanistan's attempts to promote Pathan separatism were intensified in 1955 when the North-West Frontier province was integrated with West Pakistan, and led to an armed incursion of the tribes on the other side of the Durand line in the Bajaur sector in Sept. 1960 and again in March 1961. For a time diplomatic ties between the two countries were broken off. From 1963, however, the Pakhtunistan agitation ceased.

NORTHWEST PASSAGE, a sea route along the north coast of North America between the Atlantic and Pacific oceans. Search for the passage commenced in the 16th century when Europeans became eager to discover a short route to the riches of the far east, and the great chartered trading companies of England were outstanding sponsors of early expeditions that probed the eastern Arctic for routes. The vast prolonged search for Sir John Franklin's lost expedition of 1845 contributed much to Arctic knowledge. In 1854 Robert McClure first completed a crossing, partly on foot, and in 1903–06 Roald Amundsen in the 47-ton "Gjöa" first sailed the passage, traveling east to west. The Royal Canadian Mounted Police schooner "St. Roch" made the first west to east passage (1940–42) and the first entirely in one season (1944). All four potentially feasible routes pass through Lancaster sound, suffer handicaps from rock-strewn passages in the east and shallow waters in the west and require reinforced ships, usually icebreaker escort, and ice reconnaissance to combat heavy ice. *See* also ARCTIC, THE: *Northwest Passage.* (J. R. M.)

NORTHWEST TERRITORIES, that part of Canada lying outside and to the north of the provinces but excluding the Yukon territory (*q.v.*). The territories extend from the northern limits of North America south to the 60th parallel of north latitude west of Hudson bay; farther east the boundary is drawn to include the islands in Hudson bay, Hudson strait and Ungava bay but to exclude the mainland of Labrador-Ungava. To the west, the boundary with the Yukon territory corresponds roughly with the watershed of the Mackenzie-Yukon rivers; and to the east the boundary is the limit of territorial waters except in the northeast where it lies midway between Canada and Greenland in the narrow seas extending from Smith sound to Robeson channel. Canada also claims sovereignty over any islands that remain to be discovered in the Arctic ocean in the triangular sector formed by the north pole at the apex and the meridians 60° west and 141° west. Such islands would also lie in the territories.

The political unit of the Northwest Territories evolved from "Rupert's Land and the North-Western Territory," which were acquired by Canada from the Hudson's Bay company in 1869, and from the British possessions farther north which were annexed ten years later. With the creation of new provinces and the extension of older ones, the Northwest Territories were reduced in area, until by 1920 they reached the area of 1,304,903 sq.mi. They were divided for administrative purposes into three districts: Keewatin, which was formed in 1876, when it included large parts of Manitoba and northwestern Ontario; and the districts of Mackenzie and Franklin, which were created in 1895. The boundaries were drawn so that all the islands except those in Hudson bay lay in Franklin, the land tributary to Hudson bay was included in Keewatin and the area adjacent to the Mackenzie river formed the district of Mackenzie. In the 1960s it was proposed that the territories be divided into Mackenzie territory, including the mainland west of the 105th meridian and Banks, Victoria and a few other small islands, and the territory of Nunassiaq, consisting of the districts of Keewatin and Franklin (less the islands in Mackenzie) and that part of the former Mackenzie district east of the 105th meridian.

Physical Geography.—Climate and scenery vary widely in the territories which contain both the highest mountains in eastern North America and some of the broadest lowlands. Dominating the geography and forming a fundamental division is the tree line. More accurately described as a zone of transition, the tree line extends from the delta of the Mackenzie to Hudson bay, near Churchill, Man. To the north and east are the treeless barren grounds that by geographical definition constitute the arctic; to the southwest and covering less than a quarter of the territories is a section of the Canadian boreal forest.

Although trees are not found in the arctic, woody shrubs, particularly the willow, are widespread. Close to the tree line they may reach a height of 10 ft. in sheltered valleys and may form extensive thickets. Such luxuriant growth is frequently found from Bathurst inlet to the Mackenzie delta, but is more limited around Lake Harbour, southern Baffin Island. Arctic vegetation is extremely varied. In the west rich grasslands are common while on some of the far northern islands, on the plateaus and on the limestone plains vegetation is absent. Marshland is significant in places, notably on Southampton Island and east of Foxe basin. Wherever there is plant life the short arctic growing season leads to a brief but often spectacular flowering period after the snows melt; at this time the tundra is covered with colour. The rate of plant growth is slow and, although the vegetation often appears rich, it requires long recuperation after being cropped by animals.

Trees extend into the barren grounds along such rivers as the Thelon and Coppermine, often giving a false impression of the timber resources; the higher exposed land between the rivers may retain its tundra vegetation for 100 mi. or more southwest of the tree line. Although the boreal forest in the south of Mackenzie district is a coniferous forest dominated by white and black spruce, there is an admixture of deciduous trees including poplar, aspen and paper birch. Spruce attains considerable size along the Mackenzie but only in the better drained areas south of Great Slave lake are the stands large enough for commercial exploitation.

The climate of the territories shows considerable differences between the Mackenzie lowlands and the remainder of the area. The former is relatively warm in summer; mean July temperatures of 60° F. (about 16° C.) are found along the Mackenzie river as far as the Arctic circle. At least once a year the temperature exceeds 90° F. (about 32° C.) along the southern part of the river and a high of 103° F. (about 39° C.) was recorded at Fort Smith. The summers are generally pleasant with long periods of sunshine and limited precipitation (four to five inches in the four months June to September), although this is the wettest part of the year. The winters in contrast are long, dark and cold. The mean temperature in the three months January to March varies from −15° to −20° F. (−26° to −29° C.) with occasional readings each year below −50° F. (−46° C.). Winds are light, however, and the snowfall is not heavy.

The climate of the rest of the territories is more rigorous. The dividing line between the two regions is frequently strongly marked, particularly in the spring when the temperature may drop 20° over a distance of 100 mi. northeast from the Mackenzie lowland. The arctic sector of the territories has little summer; temperatures remain in the 30°–40° F. range except at some inland points. The weather is generally cloudy and continuing light rain is common. Winter begins when the mean temperature falls below the freezing point, generally in the first half of September, and lasts until it rises above the same point sometime in late June or July. The winters are therefore long, with continuous darkness for many weeks in the northern islands. Temperatures are rarely lower than those of the Mackenzie valley but are frequently accompanied by strong northwesterly winds. Snowfall in the central arctic and far north is light but increases rapidly toward the east coast where over 200 in. have been recorded in some winters.

Over three-fourths of the territories is in the arctic but because of the low snowfall there are no large ice fields except in the highlands of Baffin, Bylot, Devon and Ellesmere islands, where ice caps and innumerable small glaciers are found; at only a few points does the ice reach the sea, being mainly restricted to the plateaus.

Elsewhere there are only minute glaciers, the most westerly being on Melville Island. On the mainland permanent ice is restricted to the local glaciers in the Mackenzie mountains.

Mean annual temperatures throughout the territories are far below the freezing point and in consequence the ground is permanently frozen except south of Great Slave lake, where there are scattered areas having permanently frozen subsoil, or permafrost (*q.v.*). The depth of the permafrost is not known, although it is probably in excess of 1,200 ft. in the northern islands. The thickness of the active layer (the upper layer of ground that thaws in summer) varies, depending on many factors, but in general it is many feet in the southwest of the territories and only a few inches in the north. Permafrost causes many construction difficulties. The problems are generally most severe in fine-grained soils such as silts, particularly common in the western Canadian arctic and the lower Mackenzie valley. This was one of the major factors which made it necessary to move the town of Aklavik, from a site in the Mackenzie delta to higher ground to the east of the delta (1954–58). Permafrost is also present in the eastern part of the territories but the problems associated with it are less severe there because of the nature of the soil.

Sea, lake and river ice conditions are serious throughout the territories; shipping comes to a complete halt in October and November. All the seas including Hudson bay are completely frozen over in winter. The first open water appears off the east coast in May but it is not until late July that shipping can move with any certainty. Hudson bay, Hudson strait and the seas adjacent to the northwest mainland become virtually clear of ice by late summer but elsewhere pack ice remains; many of the channels between the Queen Elizabeth Islands and the Arctic ocean are never passable. The Mackenzie, the only river that carries any appreciable traffic, is open from June to mid-October, although toward the end of the season low water often restricts navigation.

Physiographically the territories may be divided into five major regions. On the west, bordering Yukon territory, are the Mackenzie, Franklin and Richardson mountains, which are the northern extension of the Rocky mountains. The average height of the peaks is about 6,000 ft. with a few summits over 7,000 ft. To the east forming the second region are the Mackenzie lowlands which have developed on horizontal sedimentary rocks, mainly limestone and sandstone. Although the lowlands are for the most part plains with numerous lakes and poorly drained areas, they also contain small groups of hills such as the Cariboo and Horn mountains. The Mackenzie river flows in the lowlands except between Wrigley and Fort Good Hope where it occupies a deep valley between the Franklin and Mackenzie mountains. Two large lakes, Great Bear and Great Slave, are found in the east part of the Mackenzie lowlands on the edge of the third region, the Canadian shield.

The Canadian shield occupies virtually all the remainder of the Mackenzie and Keewatin districts. It is formed of crystalline rocks in places overlain with basaltic lavas, notably on the south side of Coronation gulf, and with sandstones, particularly along the Thelon river. The scenery varies from rock hills along the western margin and on the northwest side of Hudson bay to broad sand and clay-covered plains in the centre. In the Franklin district the shield forms a fourth region where it rises in Baffin, Bylot, Devon, and Ellesmere islands to make a mountainous, deeply dissected fjord rim to the continent. Physiographically associated with this region, although geologically distinct, are the mountains of northern and western Ellesmere and Axel Heiberg islands. The remainder of the arctic archipelago may be considered scenically one region although in detail it is complex. In a pre-Ice Age era the islands and channels were apparently one land mass drained by rivers flowing in broad valleys. Subsequently the sea partially drowned the land to produce a maze of channels separating some of the largest islands in the world, including Baffin Island (183,810 sq.mi.) and Victoria Island (81,930 sq.mi.). The land is underlain by arches of shield rocks, broad horizontal areas of limestones and sandstones and more restricted folded rocks. Today they form low hills, plateaus and plains, often covered with thick layers of shattered rock and clay.

History.—The earliest records of exploration in the territories are those of Martin Frobisher, who in 1576 examined the southeast coast of Baffin Island in a search for a northwest passage. When other voyages in the next 55 years failed to discover the passage, interest in the arctic ceased. In 1670 the Hudson's Bay company was granted a trading charter and established posts around the southern shore of Hudson bay. Apart from short voyages on the west side of the bay early in the 18th century, the company undertook no arctic exploration. The first account of the interior of northern Canada was published after Samuel Hearne on his third attempt (1770–72) had walked 2,000 mi from Churchill to the vicinity of Coppermine on the Arctic ocean in a search for native copper. Meanwhile French traders from Montreal were advancing along the prairie rivers. When trading recommenced after the conquest of French Canada in 1760, their successors were able to begin the exploration of the Mackenzie river system. By 1788 Peter Pond had mapped the waters of the upper Mackenzie and had established a trading post on Great Slave lake. The following year Alexander Mackenzie of the Northwest company descended to the mouth of the river that bears his name. Trading rivalry along the Mackenzie river was intense until 1821, when the Hudson's Bay company absorbed the Northwest company.

European penetration into arctic Canada in the 19th century was mainly concerned with renewed exploration for the northwest passage. The search for the lost Franklin expedition of 1845 led to the mapping of many of the arctic islands and the discovery of the northwest passage (*see* FRANKLIN, SIR JOHN). By this time temporary shore whaling stations had been established on Baffin Island and small semipermanent settlements soon followed. After the Dominion of Canada obtained the Hudson's Bay territory in 1869 and the northern islands in 1880, there were a number of federal government expeditions. The territories have been mapped from air photographs, though detailed exploration continues.

Resources.—Until relatively recently wildlife was the only important natural resource of the territories. Animals provided the main source of food and clothing for the native peoples, and the furs and ivory, whalebone and blubber from sea mammals were the only objects of commercial value. The most important large land mammals were the barren-ground caribou and the musk oxen in the arctic, and the woodland caribou and wood buffalo (bison) and moose in the forest. At the end of the 19th century the barren-ground caribou was found throughout the arctic sector of the territories; it was hunted by Eskimos from spring to fall and by the Indian in the winter when parts of the caribou herds migrated to the edge of the boreal forest. The introduction of firearms among the native peoples led to a rapid decrease in the caribou. They vanished from many of the islands; on the mainland, herds which numbered 1,750,000 at the beginning of the 20th century had been reduced to 200,000 by the beginning of the second half of the century. The caribou Eskimos of central Keewatin, who depended entirely on the caribou for food, were reduced to starvation and relocation became essential for their survival.

In 1935 a herd of 2,370 reindeer was driven from Alaska to the east side of the Mackenzie delta in an effort to introduce a domesticated animal into the Eskimo economy. The experiment had only limited success. Growth was slow and after 20 years there were about 6,000 reindeer. The original herd was split into four; three herds were maintained by the federal government for the benefit of the native population and a fourth was privately owned. A controlled herd of 1,200 wood buffalo was maintained in Wood Buffalo park south of Great Slave lake. Excess animals are slaughtered annually for meat.

Musk oxen were once numerous but in the 19th century, after buffalo robes were no longer obtainable, musk oxen skins increased in value and they were hunted extensively. In view of their possible extermination on the mainland, musk oxen were given total protection in 1927 and their numbers increased thereafter, particularly in the Thelon game sanctuary. They continued to be numerous in the unpopulated far northern islands.

Among the smaller mammals the white fox has been most significant. Found throughout the Canadian arctic, it has been the

main article of commercial value since the beginning of the 20th century when the first fur trading settlements were established north of the tree line. Rapid changes in the value of fox pelts in response to world demand and unrelated to natural fluctuation in fox numbers made it an unstable base for Eskimo economy. Indians trap muskrat, mink, beaver and some other fur-bearing animals along the Mackenzie river. Fur production for the territories normally is valued at more than $1,000,000 annually.

The original economic motive bringing Europeans into the Canadian north was the search for sea mammals, particularly the whales, but overfishing and falls in world prices reduced that activity to negligible proportions. Seals, walrus and in some areas white whales are still important to coastal Eskimos. Fish have always been a limited source of food for Eskimos and Indians. Beginning in 1945 attempts were made to establish commercial fisheries. The most immediately successful was at Great Slave lake, where from 5,000,000 to 9,000,000 lb. of whitefish and lake trout, valued at $1,000,000 to $2,000,000 was taken annually.

Land suitable for agriculture is limited and is found only in the Mackenzie valley. In the second half of the 20th century there were only six farms of more than three acres and the cultivated area was less than 100 ac.

Undoubtedly the most valuable resources of the territories are the minerals. By analogy with the section in southern Canada, the Canadian shield was expected to contain rich deposits of metallic minerals, and the sedimentary rocks of the Mackenzie lowland and the arctic islands, petroleum and natural gas. By the second half of the 20th century, however, there had been widespread prospecting only in the vicinity of the Mackenzie valley where river transportation could be used in any development.

Oil seepages were discovered at Norman Wells on the lower Mackenzie river in 1911 but oil was not produced on a commercial scale until the early 1930s. Production increased at Norman Wells after newly established mines along the Mackenzie river created a market. During World War II a 400-mi. pipeline was built across the Mackenzie mountains to Whitehorse, Yukon territory; in 1944 production reached a peak of 1,223,675 bbl. Thereafter oil was supplied only to the Mackenzie valley and the western arctic; annual production during the 1950s was about 1,000,000 bbl.

The next mineral resources to be developed were the pitchblende ores at Port Radium at the east end of Great Bear lake in 1930. At first radium was the main product with copper, silver and cobalt subsidiary. The mine closed for a short period in the early part of World War II. When it reopened a few years later the main product was uranium, which was later mined north of Great Slave lake. The Port Radium uranium mine was closed again in 1960 when ore reserves were used up. In 1933 gold was discovered at Yellowknife on the north arm of Great Slave lake and production began five years later. These mines became the most important in the territories, and they form the economic basis for the largest town, Yellowknife (pop. [1961] 3,245).

Nickel and copper mining began in 1957 in the arctic at Rankin Inlet on the west side of Hudson bay. Other nickel deposits are known in the same area, as well as copper and nickel near Coppermine, iron ore on Baffin Island and lead-zinc at Pine Point. Commercial development of these areas is hindered by high transportation costs. Hydroelectric plants were constructed on the Snare river, 94 mi. N.W. of Yellowknife and at Bluefish lake, 15 mi. N. of the same town.

Government.—Government is in part directly by the federal government from Ottawa and in part by a territorial legislative body, the council, with approximately the same responsibilities as a Canadian provincial government. The council is composed of nine members, five of whom are senior government officials appointed by the governor general-in-council; the remaining four are elected by the residents of four constituencies in the Mackenzie district. Administration is the responsibility of a commissioner who acts under instructions from the governor general-in-council and the minister of northern affairs and national resources.

Population and Settlement.—The population of the territories in 1921 was 8,143, in 1941 was 12,028 and in 1951 was 16,004. In 1961 it was 22,998, of which about one-fifth was Indian and one-third Eskimo. The Indians and about 1,500 Eskimos live in Mackenzie district. The Indians for the most part occupy settlements along the Mackenzie river; fur trapping, fishing and hunting are their principal occupations. The Eskimos are more widely distributed, being found throughout the arctic section of the territories (except for some of the far northern islands) and in the Mackenzie delta. When Europeans first visited the Canadian arctic they found Eskimos in isolated seminomadic groups around the coasts, where they lived on sea mammals, and in the interior of Keewatin, where they were dependent on caribou and fish.

The earliest European settlements were established by fur trading companies in regions where natives were known to congregate, particularly in the winter and early spring in areas where trapping was thought to be rich, or at places which the natives could easily reach. In the northwestern forest all settlement was along the Mackenzie river and its tributaries; in the arctic (with the exception of Padlei, in southern Keewatin), the posts were located at points that could be reached by ships. Many of the Mackenzie settlements were founded in the early 19th century but the oldest existing arctic settlements are only 50 years old.

The first government representatives were the Royal Canadian mounted police; as the responsibilities of government expanded, nursing stations and hospitals were created in the larger communities and traveling medical, dental and X-ray units visited the smaller settlements at least once a year. The first schools were operated by missionaries; by the 1960s there were about 40 federal schools, some of which were boarding schools.

At first the settlements had little effect on the distribution of the population, which had to remain on the traditional hunting grounds in order to obtain sufficient fur-bearing animals and food. As the settlements grew, however, they attracted more and more Indians and Eskimos who came to live permanently in the vicinity, often in wooden cabins. Food was still partly obtained by hunting but was augmented by purchases with family allowances and government relief. By 1939 the growth of mining towns in the Mackenzie lowland had already begun to influence the population distribution in the west. In the arctic it was not until 1955 that government policy and military developments led to significant population changes.

During World War II the construction of airfields in the eastern arctic at Coral Harbour, Southampton Island, and at Frobisher Bay, Baffin Island, made access to these areas much easier and led to the employment of some Eskimos. However, it was not until the building of the Distant Early Warning (DEW) line—a network of installations across the 70th parallel which report and plot aircraft operations in the polar regions—that a widespread demand developed for Eskimos who could speak some English and had manual skills. Many moved into the construction camps and earned high wages. After the DEW line building program was completed some Eskimos remained on the sites; others found their way to northern settlements where further employment was available. The most important of these settlements in the eastern arctic is Frobisher Bay. The Frobisher Bay airfield, operated by the Canada department of transport, is used by transpolar flights to Europe from the west coast of North America. Frobisher Bay, the largest town in the North American arctic (pop. [1961] 512), became the administrative centre in the eastern arctic. A second town in which federal government planning was active was a new town, Inuvik, built to replace Aklavik in the Mackenzie river delta.

No Eskimos were living in the far northern islands when they were first explored, although there had been in prehistory. In the 1960s settlement in the islands was restricted to four weather stations supported from a main base created in 1946 at Resolute Bay, Cornwallis Island. Some Eskimo families had been relocated in the northern islands from impoverished areas farther south.

The largest communities in the whole of the territories are not, however, a direct outgrowth of the trading settlements. They are the mining towns of Yellowknife, Port Radium, and Rankin Inlet, as well as some of the more complex settlements along the Mackenzie river.

Transportation.—Economic development of the territories has

been hampered by the lack of transport facilities. Until about the middle of the 20th century the usual form of transportation was by water; in Mackenzie this meant the Mackenzie river system. Traffic for the western arctic originates at railhead at Waterways, Alta., and is carried north from there by tug and barge, with transshipment by road around a 16-mi. stretch of rapids between Fort Fitzgerald and Fort Smith. From there, boats can reach Tuktoyaktuk on the Arctic ocean, where there is a second transshipment for ports in the western arctic. The shallowness of the channels in this area restricts shipping to schooners and small vessels. All coastal settlements in the eastern arctic are reached by sea and until the end of World War II were visited only once a year by ships. Expansion of the settlements and the rapid growth of military installations, particularly those associated with the DEW line, resulted in convoys of ships escorted by icebreakers penetrating northern waters. Harbour facilities are lacking and all unloading is by lighter.

In the Mackenzie district an all-weather transportation route was opened in 1949 with the completion of the Mackenzie highway from Grimshaw, Alta., to Hay River on Great Slave lake. Construction was continued thereafter to extend that road around the north end of Great Slave lake to Yellowknife and northward into adjacent mining areas. During the winter months tractor trains operate from many western settlements moving supplies and heavy equipment to isolated points. Construction on the 438-mi. Great Slave Lake railway, the first railway to cross the 60th parallel into the territories, began in 1962.

Passenger transportation has been provided increasingly by aircraft. Construction of all-season airstrips in many parts of the territories permitted scheduled flights by various companies along the length of the Mackenzie valley, to Cambridge Bay on Victoria Island, and to Frobisher Bay on Baffin Island. Where large aircraft are not warranted smaller airplanes on wheels, skis or floats operate from various centres, including Fort Smith, Yellowknife, Hay River, Aklavik and Frobisher Bay. The far northern weather stations and some of the DEW line sites are serviced entirely by aircraft.

NORTHWICH, a market town, urban district and parliamentary division of Cheshire, Eng., 17½ mi. E.N.E. of Chester by road, at the confluence of the Weaver and Dane rivers. Pop. (1961) 19,542. Northwich's streets are narrow and irregular, with some houses at fantastic angles because of subsidence resulting from the pumping of brine. Its brine springs have been used since Roman times, and the chemical industry, developed from the older salt trade, is a large concern. The centre of the salt trade moved to Winsford, several miles away, and the old Salt union has become the Salt division of Imperial Chemical Industries. There are also steel and iron works, leather, carpet and clothing factories.

NORTON, CAROLINE ELIZABETH SARAH (1808–1877), English poet and novelist, whose matrimonial lawsuits made her a notorious figure in Victorian society, was born in London, probably on March 22, 1808. One of the three beautiful granddaughters of the dramatist Sheridan, in 1827 she married the Hon. George Norton, brother of Lord Grantley. He proved to be a dull, quarrelsome husband, content to live off his wife's earnings and to make use of her Whig connections. Her friendship with Lord Melbourne secured him a judgeship, but in 1836 he brought an action against Melbourne for seducing his wife. This may have been a political move designed to discredit Melbourne, for the evidence was flimsy and the jury decided against Norton without leaving the box. He then refused his wife access to their children and her pleas were instrumental in introducing the Infant Custody bill, which was finally carried in 1839. In 1855 she was again involved in a prominent lawsuit when her husband refused to continue her allowance. Her indignant protests, which included *A Letter to the Queen*, had a great influence on the Marriage and Divorce act of 1857 which abolished some of the injustices to which married women were exposed.

Mrs. Norton's main outlet was her literary activities. She began writing while still a child, when a bookseller published her light-hearted satire, *The Dandies' Rout*, and she published volumes of poetry throughout her life. Her reputation stood high among her contemporaries: her name was coupled with that of Elizabeth Barrett Browning, and Hartley Coleridge, reviewing *The Dream, and other Poems* (1840) in the *Quarterly*, hailed her as "the Byron of modern poetesses." She also wrote four novels based mainly on her own unhappy experiences, edited various literary annuals and wrote many popular songs. She was a passionate, generous, indiscreet woman, whose charm is well conveyed by the portrait of her in *Diana of the Crossways* (1885) by George Meredith (*q.v.*), in which a painful incident in 1845, when she was wrongly supposed to have sold to the *Times* a political secret thought to have been revealed to her by her close friend, Sidney Herbert, is treated as true. Her husband died in 1875, and she had a brief period of happiness as the wife of Sir William Stirling-Maxwell before her death in London on June 15, 1877.

See J. G. Perkins, *The Life of Mrs. Norton* (1909); A. Acland, *Caroline Norton* (1948).

NORTON, CHARLES ELIOT (1827–1908), U.S. scholar and man of letters, was an idealist and reformer by temperament, who exhibited remarkable energy in a wide range of activity. Born in Cambridge, Mass., on Nov. 16, 1827, and graduated from Harvard in 1846, he opened a night school in Cambridge; was director of a housing experiment in Boston; worked zealously as an editor for the Union cause; was coeditor (1864–68) of the *North American Review* and one of the founders of the *Nation* (1865). From 1874 to 1898 he lectured on the history of art at Harvard, where he was one of the most popular teachers of the day and an "oracle of the humanities." A friend of many literary greats, including Carlyle, Emerson, Ruskin, Longfellow and Lowell, he contributed valuable editions of their letters and other biographical material.

Norton also wrote on art and edited collections of poetry, notably the poetry of John Donne (1895, 1905). Probably his best literary work was his prose translation of the *Divine Comedy* (1891–92). His *Letters . . . With Bibliographical Comment* were edited by Sara Norton and M. A. De Wolfe Howe (1913). Norton died on Oct. 21, 1908.

See E. W. Emerson and W. F. Harris, *Charles Eliot Norton* (1912); T. W. Higginson, *Carlyle's Laugh* (1909).

NORTON, THOMAS (1532–1584), English poet and playwright who, with Thomas Sackville, wrote *Gorboduc*, the earliest English tragedy, was born in London in 1532. Educated at Cambridge and admitted to the Inner Temple, London, in 1555, he contributed to *Tottel's Miscellany* (1557) and to Thomas Sternhold and John Hopkins' rhyming psalter (1562). He wrote *Gorboduc* in 1560; it was first printed in 1565 (*see* SACKVILLE, THOMAS; ENGLISH LITERATURE). He also translated John Calvin's *Institutes of the Christian Religion* (1561) and Alexander Nowell's *Catechism or First Instruction of Christian Religion* (1570).

Norton became member of parliament for Berwick in 1562 and entered into political and religious controversy, writing numerous anti-Catholic pamphlets. His punishment of the Catholics, as their official censor from 1581 onward, earned him the nickname of "rackmaster-general." At last he was deprived of office and thrown into the Tower of London. He died soon after his release, on March 10, 1584, at Sharpenhoe. (P. Dw.)

NORWALK, a city of Fairfield county, Conn., U.S., is located 14 mi. W.S.W. of Bridgeport on Long Island sound at the mouth of the Norwalk river. The site, purchased from the Indians in 1640 by Roger Ludlow and Daniel Patrick, was first settled in 1649 by a small group of colonists from Hartford.

In 1779, during the American Revolution, Norwalk was burned by Loyalist forces under Gen. William Tryon, colonial governor

New York, and it was from Norwalk that Nathan Hale crossed Long Island sound to Huntington, L.I., where he was captured by the British and executed as a spy. The manufacture of hats, long the town's principal industry, was begun before the Revolution. In the 19th century Norwalk was an important centre for shipbuilding and the production of earthenware, coaches, wagons, sleighs, tallow candles and shoes. Later textiles, clothing, electric and electronic equipment, typewriters and rubber products were added to the list of manufactures. From the time of first settlement Norwalk oysters were famed for both quality and quantity. After 1880, however, the oyster fishery declined because of overexploitation of the oyster beds and inadequate legal regulation of the industry. The rapid industrialization of the 20th century and the pollution of the waters by industrial wastes brought Norwalk's oystering virtually to an end.

The town of Norwalk, organized in 1631, contained two cities, Norwalk (incorporated as a borough in 1836 and as a city in 1893) and South Norwalk (incorporated in 1870), as well as the villages of Rowayton, East Norwalk, West Norwalk, Cranbury, Winnipauk, Silvermine and Broad River. In 1913 all this territory was consolidated and incorporated as the city of Norwalk. Pop. (1960) 67,775; standard metropolitan statistical area (Norwalk, Westport and Wilton), 96,756. For comparative population figures *see* table in CONNECTICUT: *Population*. (GL. W.)

NORWAY (KONGERIKET NORGE; KINGDOM OF NORWAY), is a country of northern Europe, occupying the western and smaller part of the Scandinavian peninsula. Its eastern frontier borders Sweden, except in the extreme north where Norway adjoins Finland and the U.S.S.R. It is bounded on the north, northwest and west by the Barents sea, the Norwegian sea and the North sea. The Skagerrak washes it on the south and southeast. The most southerly point is the island of Kråga near Mandal, the most northerly is Cape Knivskjelodden west of the North cape, on the island of Magerøy. The northernmost promontory of the mainland is Nordkyn, the southernmost, Lindesnes. The most western island, Steinsøy, lies off the mouth of Sognefjord and the easternmost point is Hornøya, near Vardø. The length of Norway (southwest to northeast) is about 1,100 mi. The extreme breadth is 267 mi., the narrowest 4 mi. The length of the coastline is difficult to estimate; excluding indentations and islands it is about 1,650 mi., but including the fjords and the islands it is probably 12,000 mi. The total area (including water area) is 125,181 sq.mi.; and, including Svalbard (*q.v.*), the Spitsbergen group of arctic islands, 149,139 sq.mi. Small islands also under Norwegian rule are Jan Mayen in the Arctic sea, and Bouvet and Peter I in the Antarctic. Queen Maud Land, on the Antarctic continental coast between longitude 20° W. and 45° E., is also under Norwegian control. The capital of Norway is Oslo.

This article is arranged in the following sections and subsections:

I. PHYSICAL GEOGRAPHY

1. Geology and Structure.—The rocks of Norway south of Hardangerfjord are mostly of Pre-Eocambrian age, consisting largely of schists, gneisses and migmatites of various kinds with basic, anorthositic intrusions near Egersund, and a few equally ancient sedimentary rocks in the Norefjell area. These Archaean rocks are interrupted in the Brevik-Drammen-Oslo-Hamar area by a fault-shattered belt about 20 mi. wide of lavas and plutonic rocks of Permian age flanked, especially on the western side and also at Oslo, by Cambro-Silurian sediments.

North of this is a square area, which includes Gudbrandsdal (*q.v.*) and the mountain massif of Rondane, of Eocambrian sparagmites and other sedimentary rocks, perhaps of similar age to the Torridonian of western Scotland. Between Rondane and Kvenangen, north of Tromsø, the rocks are largely of Cambro-Silurian age with a return of Eocambrian sedimentaries in northern Finnmark, and Pre-Eocambrian in southern Finnmark.

There are several small areas of Devonian rocks, mostly sandstone and conglomerate, such as in the Solund Islands (Solundøyane) at the mouth of Sognefjord, north of Florø and at Stjørna, near the mouth of Trondheimsfjord. The youngest solid rocks of Norway occur at Andøy, the most northerly island of the Vesterålen group, where there is a patch of about five square miles of Jurassic-Cretaceous rocks. Apart from this there are no Mesozoic-Tertiary sedimentary rocks in the whole of Norway, which is, in fact, one of the oldest land masses in the world.

Structurally the country may be divided into three areas by two lines: (1) along Hardangerfjord, through Granvin, Ulvik, north of Finse and Gol to Gjøvik; (2) north-northeast from the west coast about ten miles south of Bergen, to cross Sognefjord between Vik and Leikanger; continuing northeast, it separates Jostedal from Jotunheim, passes through Lom and thence north of Rondane to a little south of Røros, beyond which it passes into Sweden. The structure of the area to the south of the "Hardanger" line is of Cambrian or Pre-Cambrian age, although it may have been modified slightly by later earth movements. To the north of the "Leikanger" line the structure is almost entirely of Caledonian age, and the rocks have mostly been greatly altered from their original form, often to such an extent that it is now almost impossible to place them in the geological sequence. This applies especially to those in the western half of the country between Bergen and North Trøndelag.

Between the lines lie the great thrust belts of the Bergen arcs, the Gudvangen area, and the Jotunheim. The whole of northern Europe from Scotland to Scandinavia experienced a considerable compression in the mountain building stage of the Caledonian orogeny, which came to a culmination at the end of Silurian times. At that period, the Baltic Shield (now southern Norway, Sweden, Finland and the land to the east) moved nearer to North Atlantis, the continental land mass then to the west of Scotland. This produced great contortions, folds and faults in the rocks between. At either edge of the compression, that is, on the west coast of northern Scotland and in the belt between the Leikanger and Hardanger lines of Norway, the peripheral areas were forced to ride over those beyond, as great thrust masses. In Norway, the western rocks moved over the more easterly, and the area between the two lines is one of numerous overthrusts of great complexity. North of Røros the thrust planes are in Sweden, but they return to Norway in the far north, and divide Finnmark into the Pre-Eocambrian on the southeast of the line, which runs from near Reisduoddarhaldde to Rastigaissa and Tanafjord, and the altered Eocambrian rocks to the northwest.

At the same time, as is usual in such circumstances, there was considerable igneous activity. This formed an almost continuous

intrusion of granitic rocks south of Nordland to Sagfjord, and gabbro in the extreme west of Finnmark. Lofoten and Vesterålen comprise plutonic rocks, largely granite and syenite, which are also thought to be of Caledonian age, although this is not certain. The "Lofoten wall" is a striking topographic feature which seems to mark the boundary between massive rocks and the schistose gneisses to the southeast.

The Bergen arcs are a number of bands of varied igneous and altered rocks whose outcrops form a series of arcs centred on Bergen from whence their name is derived. They result from a horizontally curved folded structure of somewhat complex pattern, but since the different rocks are of more or less alternating resistance to erosion, the relief has a banded pattern and a series of concentric ridges and valleys encircles Bergen city on its eastern side.

Such intense compression as these Caledonian movements produced could not result merely in a simple set of thrusts, and there is a detached area of Cambro-Silurian sediments and Caledonian intrusive rocks with numerous thrust planes in the area from Jaeren to Hardangervidda.

2. Physiography.—*Mountains.*—Although these Caledonian structures are very much younger than the Pre-Cambrian and Pre-Eocambrian rocks, they still belong to relatively early geological time, and probably about 400,000,000 years have elapsed since this great upheaval. During that long period, the area has been land, and weathering and erosion have gradually worn away the rocks, until what is now left are the mere remnants of these ancient masses.

There is scarcely any lowland, and even the 20% of the country which lies below 500 ft. is mostly hills or valley floors. It seems certain that the erosive action of rivers had reduced Norway to a gently rolling peneplain by Miocene times with some mountain ranges such as the Jotunheim, Dovre and Rondane massifs rising about 3,300 ft. above it. Gentle, but long-continued, uplift then elevated this plain, so that its surface now forms the plateau of Jostedal and the accordant summit levels around Geirangerfjord to the north and the Hardanger district to the south, all at about 5,000 ft. This uplift greatly accelerated the flow of the rivers, and a new era of active downcutting was initiated. The valleys were deepened and especially rapid erosion occurred on the highest mountain summits, so that the Jotunheim, Dovre and Rondane now project less than 2,000 ft. above the fjeld, the elevated remnants of the old plain.

The highest peaks in Norway are in these areas. Galdhøpiggen (8,100 ft.) and Glittertind (8,104 ft.) are the only two to exceed 8,000 ft., and are both in the Jotunheim. The highest peak in Dovre is Snøhetta (7,474 ft.), and in Rondane there is Rondeslottet (7,162 ft.).

A further uplift in Pliocene times introduced a tilt, so that in southern Norway the *vidde* or high plain which is peripheral to the Miocene plain already described, descends from 3,600 ft. in the west to 2,300 ft. in the southeast. Occasional residual mountains rise out of this, as, for example, Gausta, 6,178 ft., near Rjukan.

Eastern Norway (*Østlandet*).—Tertiary earth movements intensified fluvial erosion and so have had a great influence upon the present topography. In the east (Østfold, Akershus, Hedmark, Oppland, Buskerud, Vestfold and Telemark) the drainage is south or southeasterly. The principal valleys and rivers often change name along their length, but they are generally known as: Østerdal, with the Glomma river (*q.v.*), 365 mi. in length, the longest Norwegian river; Gudbrandsdal, with the Lågen river, flowing into Lake Mjøsa (*q.v.*), the largest lake in Norway, 141 sq.mi. in area and 1,473 ft. deep, the outlet of which is the Vorma river, a tributary of the Glomma; Valdres-Begnadal-Ådal, which enters Tyrifjord (a lake); Hallingdal, where the Snarum river joins the outflow from Tyrifjord and becomes the Drammen river (*q.v.*; 192 mi.); Numedal (Lågen river, 212 mi.); and Tinnedal (Tinne river). The region is mountainous and the valleys carry the chief railways and roads converging on the coastal area between Kragerø and Oslo. Oslofjord primarily occupies a partly infilled and partly reexcavated geological graben. It has an area of 766 sq.mi. and is 62 mi. in length. Compared with the west coast fjords, its sides are relatively low. At the seaward end it is flanked mostly by bare rock, but the inner parts are wooded.

This part of Norway has the greatest number of lakes—many thousands. The general lower relief of the *vidde* as compared with the high plateau and mountains of the west led to a somewhat less intense glaciation, so that most of the valleys were not deepened sufficiently to be drowned by the sea and become fjords. Yet the glaciers modified the river profiles to produce frequent rock hollows, now flooded to form finger lakes.

Southern Norway (*Sørlandet*).—Aust- and Vest-Agder could be termed Southern Norway. The topography is very similar to that of eastern Norway with very little lowland beyond the river valleys. The principal ones are Niddal or Arendal (99 mi.), Tovdal (91 mi.), and Otradal with Setesdal (150 mi.). The coast is rocky along its whole length, and although very much indented contains only three fjords of any size. These are Topdalsfjord near Kristiansand, Lyngdalsfjord near Farsund, and Fedafjord.

Western Norway (*Vestlandet*).—The western portion of southern Norway comprises Rogaland, Hordaland, Sogn og Fjordane and Møre og Romsdal. It is the area of the greatest fjords and some of the most spectacular mountain and valley scenery. The fjords are characterized, especially in their upper reaches, by their precipitous sides which often rise 3,000 to 5,000 ft. almost sheer out of the water, and by their great but irregular depths. The deepest sounding in Sognefjord (*q.v.*) is 4,291 ft. The fjords were originally river valleys, adopted by glaciers during the Pleistocene, and greatly deepened and completely reshaped by them. At that time the North sea was dry or ice-covered, and the fact that their floors are now below sea level to their mouths is purely adventitious. As a result they are flooded by the sea and their water is salt. There are many similar valleys whose floors contain barriers of rock or moraine sufficiently high to prevent marine invasion. Hornindalsvatn (Hornindal lake) in northern Sogn og Fjordane is an example. It is the deepest lake in Europe (1,686 ft.), separated from Eidsfjord, a branch of Nordfjord, by a rock barrier only 3 mi. in length and of no great height. The lake surface is 174 ft. above sea level and has an area of 20 sq.mi. The longest fjords are Sognefjord (*q.v.*), 114 mi. (to Skjolden) and Hardangerfjord (*q.v.*), 77 mi. (to Odda). Because the fjords penetrate so far inland, the rivers are short and relatively unimportant.

Glaciation typically produces sharp steps in valley floors and also discordant valley-junctions (hanging valleys), so that Norway is a land of waterfalls. Vøringfoss, east of Hardangerfjord, has a sheer drop of 597 ft., the Syv Søstre (Seven Sisters) of Geirangerfjord, the Tokagjel falls near Norheimsund, the falls north of Odda and those at Rjukan are particularly famous. Rjukan is situated in Eastern Norway, but many of the most spectacular falls are in Western Norway. Many of the falls at Odda and Rjukan, as well as at other places, have been harnessed to produce hydroelectric power, which will probably be the most important single economic factor in Norway's future. At Rjukan the output of electricity approaches 1,000,000 horsepower, and surveys indicate that Norway could economically produce about 12,000,000 horsepower in this way, reckoning on the minimum water supply and 75% efficiency.

The glaciers often divided and thus encircled areas of land which may now have become islands. These are frequent along the whole of the west coast, but are found especially in Vestlandet. It is possible to navigate the coast with an almost continuous protection of islands on the western side, and this is so great an aid to shipping that they are termed the *skjaergård*, a similar word to the English *skerries*, and indicating "coast protector." Many of these islands are in the shelf (*strandflat*) of rather low, uneven rocky ground, which has an average height of about 150 ft. and forms a narrow fringe to the mountain land. They were created when the ice cut channels in the shelf. The *strandflat* is a true shelf, for in most parts it is bounded by cliffed mountain slopes on its landward edge and by an equally abrupt fall in level beneath the sea at its western edge. This latter is believed to be a fault scarp along most of its length, and to be genetically connected with the Norwegian channel, the great deep which lies off the south

and southwest coasts of Norway for about 560 mi. and reaches a maximum depth of 2,300 ft.; it is a true graben of Tertiary age. The inner limit of the *strandflat* is not, however, along a fault line, and it is believed that it was initiated largely by coastal glaciers at a time when the snowline was down to sea level prior, at least, to the last glaciation, and that later ice sheets smoothed out many of the irregularities left by the individual coastal glaciers. Wave action in a relatively higher-level sea has also added much to the feature, but many consider that in view of the width, plan and irregular relief of the *strandflat* it is unlikely that it was produced entirely by marine processes.

Vestlandet contains the only substantial low-lying coastal area of Norway—Jaeren, south of Stavanger. It is about 35 mi. in length and 8 mi. in width, and is the only large outcrop of Cambro-Silurian sedimentaries that flanks the open sea, which there is almost devoid of fringing islands. It provides the largest single area of arable farming in the whole country and also has considerable industrial development on sites favourable to factories.

Northern Norway (*Nordlandet*).—From Nord- and Sør-Trøndelag to Troms the country is very greatly reduced in width, and this portion, together with Finnmark, the most northerly *fylke* (county), forms Northern Norway. It is an area of high mountains and emptiness. Its countryside is largely occupied by a very great number of fairly small lakes and by wide, branching fjords. Since the glaciers there were shorter than in Vestlandet, and came from mountains of lower average height, the fjords are less deep. There are fewer islands also, although the *strandflat* is well developed. There are, however, the Lofoten, Vesterålen and Hinnøy islands. The last named is structurally uniform with the adjoining mainland across a narrow glacier-produced strait, but its southern end, which links geologically with the Lofoten group, trends toward the southwest, whereas the general trend of the main coast is here more nearly north-south. The line of islands thus diverges from the general coast and Moskenesøy, the most southerly large island of the Lofoten group, has about 50 mi. of open sea between it and the mainland. The scenery is spectacular. Small local Pleistocene glaciers eroded the land leaving precipitous, pointed peaks, the highest of which is Higrafstind (3,809 ft.) on Austvågøy. The sea around these islands is shallow over a wider area than elsewhere off the Norwegian coast, and this gives rise to the extensive fishing grounds for which the Lofotens are well known. The famous tidal whirlpool, the Maelstrom, occurs off Moskenesøy.

The topography of Finnmark differs markedly from other parts of Norway and is essentially an undulating *vidde* ranging from 1,150 to 2,000 ft. in height with a southeast-facing escarpment near the limit of the Caledonian thrusts. It is a country symbolic of icecap glaciation rather than of valley glaciers; and drumlins, eskers, ground moraine molded into long ridges, and similar glacial features are common.

Glaciers and Icecaps.—It is estimated that there are now about 1,700 glaciers existing in Norway, and that, together with plateau icecaps, they cover a total area of about 1,300 sq.mi., about half of which is in Vestlandet. Icecaps are typical of present conditions and mostly give rise to numerous short valley glaciers at places were they overflow from the plateaus. Jostedalsbreen, just north of Sognefjord, has an actual cap area of 315 sq.mi. at about 6,400 ft., and is the largest in continental Europe. It gives rise to 24 or more valley glaciers; the best known of these are Tunsbergdals-, Nigards-, Bøyum-, Suphelle-, Briksdals- and Kjenndalsbreen. Other icecaps are Folgefonni (85 sq.mi.) and Hardangerjøkulen (37 sq.mi.) to the south and northeast of Hardangerfjord respectively, and Svartisen (189 sq.mi.) and Blåmannsisen (48 sq.mi.), both in Nordland.

The only area of numerous valley glaciers not fed by icecaps is the Jotunheim, where glacial conditions in the past led to the formation of pyramidal peaks which contrast with the relatively flat top of the nearby Jostedal.

These glaciers and icecaps are not remnants of the last Ice Age, for about 3000 B.C. the temperature was at its highest (climatic optimum) in postglacial times. At that time all, or almost all, the ice would have melted. With the cooler conditions that followed, ice returned and archaeological evidence indicates that in the middle ages the glaciers were about the same size as today, although in the first half of the 18th century they were considerably larger. Most of them have been shrinking in the 20th century.

3. Climate.—The striking and unique feature of the climate of Norway is the presence of the largest positive temperature anomaly on the surface of the globe, which results in such unusual conditions as average temperatures within the Arctic circle which are higher than those of places farther east and as much as 20° S. This temperature anomaly results from the warm North Atlantic current (terminal section of the Gulf stream) and air drift across the Atlantic ocean onto the shores of Norway. January is the coldest month, and southeastern Norway then has a mean temperature of below freezing point (Oslo −4° C. [25° F.]), but the coldest parts in this area are the Glomma valley, between Tynset and Røros (near the Swedish border). At Røros (altitude 2,067 ft.) the January mean is −10.5° C. (13° F.) and an absolute minimum of approximately −37° C. (−35° F.) has been recorded. Even this intense cold has been exceeded near the Norway-Sweden boundary in Lapland. Along the western and northern Norwegian coasts winter temperatures are higher, the January mean being 2° C. (35° F.) in Bergen, −1° C. (30° F.) in Bodø and −5° C. (23° F.) in Vardø. In these coastal districts February is on the average colder than January. The number of days on which frost occurs varies between 45 at Ona and 240 in certain parts of Finnmark; North cape has about 190. The fjords are not penetrated by cold water from the open ocean and are always icefree except along shallow coastal stretches during unusually severe winters when small patches of ice form.

Summer temperatures range between slightly below 10° C. (50° F.) in the extreme north (Troms 11° C. [52° F.] July average), and 17° C. (62° F.) at Oslo in July. Røros, with much greater altitude, has 11° C. average in the same month. The southeast of Norway is the warmest part in summer. At Bergen the warmest month is also July (14° C. [57° F.] average). Absolute maxima are high: Skudenes, 29° C. (84° F.); Bergen 32° C. (90° F.); Oslo 35° C. (95° F.) and even Karasjok, in Finnmark, has recorded 31° C. (88° F.). The annual range increases from west to east generally and from south to north along the coast.

Though the southwest wind is usually prevalent over Norway and very marked in summer, yet the winter high-pressure area causes outflowing winds—northeast on the Skagerrak, south and southeast on the western coast and southwest on the northern. Gales are frequent on the western coast, averaging three to four per month in winter and one to two per month in summer. In the interior and east, gales are comparatively rare. Gales from the southwest bringing rain are the most common; next in frequency are gales from the northwest bringing snow. Calm weather is rare on the western coast but frequent in the interior. December and January are the stormiest months. Hail and thunderstorms are infrequent.

The number of days on which rain or snow falls is greatest on the northwestern and northern coasts, least in the southeastern districts and the interior of Finnmark. In the north and northwest precipitation occurs on 150–200 days in the year. On Dovrefjell and the southeastern coast the average is about 100 days. Snowfall is least frequent in the south (*e.g.*, at Mandal 25 snowy days out of 116 on which precipitation occurs), increasing to 50 days at Oslo and Dovrefjell, to 90 at Vardø and to 100 at the North cape. Hence in the north and in the upland tracts snow occurs at least as frequently as rain. Snow may fall in any month in Finnmark and in areas over 3,300 ft. above sea level. Precipitation exceeds 100 in. per annum in the mountains a few miles from the coast north and south of Sognefjord. On the outer islands there is a slight decrease; inland the decrease is rapid and great. On the eastern side of the mountain ridge, in the upper part of Gudbrandsdal, the average is less than 12 in. In the extreme south of the country the average is about 39 in. There is a diminution eastward along the northern coast and a further rapid decrease toward the northern interior, where the average is 16 in., with strongly marked local variations.

Cloudiness is intense. The coast of Finnmark has more than

three cloudy days to one clear day; in the interior of the country clear and cloudy days are about equally divided. Summer fog is frequent on all coasts but fog is rare in winter, though it occasionally occurs in the southeast. Sometimes in severe winters a frosty fog ("smoke frost") appears on the western fjords, caused by the cold land wind passing over the relatively warm water.

Norway was one of the first countries to establish a meteorological service; the Meteorological institute in Oslo was set up in 1866. There are also 825 stations where observations and measurements are taken. The stations at Bergen, on Jan Mayen Island, on Bjørnøya (Bear Island) in Svalbard and on the peaks of Fanaråken and Gausta are of special importance for weather forecasting. Forecasts are made five times a day and broadcast regionally from Oslo, Bergen and Tromsø.

4. The Midnight Sun.—Part, at least, of the sun's disk is above the horizon at the North cape continuously from May 12 to August 1, and at Bodø, in latitude 67° 17′ N., from June 1 to July 13. Even at Trondheim there is practically no night from May 23 to July 20, while the long twilight gives the extreme south of Norway no real darkness from the end of April to the middle of August. In winter, on the other hand, the sun does not rise above the horizon at the North cape for more than two months, when the aurora borealis or northern lights is often visible and there is only a twilight at midday. In the extreme south, midwinter night is 17½ hours long. (R. K. Gr.)

5. Vegetation.—The forests of Norway, which cover about a quarter of the country, consist chiefly of conifers. The principal forest regions are in the southeast and south. In the Trondheim area and in Nordland there are extensive forests of pine and spruce with the pine on the drier, higher and less congenial parts. In southeastern Norway the conifer tracts extend from sea level to about 3,000 ft.; in the Trondheim region the upper limit is 2,000 ft.; on the coast it is 1,200 ft.; farther north the spruce disappears and the upper limit of pine falls to 900 ft. at about latitude 70° N. Above and north of the conifers is the birch belt; next follow various species of willows and the dwarf birch; and below the snow line is the lichen belt in which the reindeer moss is always conspicuous but there are also a few flowering plants, shrubs and dwarf trees. Among the conifers there is a sprinkling of other trees—lowland birches, aspens and rowans in the high north, and ash, elm, lime, oak, beech and black alder in the lower south. The beech is much rarer than in Sweden and, in fact, flourishes only near the Skagerrak; there and elsewhere the extreme coastal region is destitute of forest. The richest flora is found in the inland fjord valleys. The Dovrefjell district contains within narrow limits a greatly varied arctic vegetation.

6. Animal Life.—The great forests were once the haunt of the bear, the lynx and the wolf. The bear and the lynx are now almost extinct. Wolves decreased very suddenly in southern Norway about the middle of the 19th century, probably because of disease, and continued to decrease thereafter in the north, but they are still found in the Røros district and northward to Finnmark where they are more common. Wolves are the worst enemy of the reindeer. The elk occurs in the eastern forests and near the coast in the Trondheim district. The red deer is confined chiefly to the western coast between the Haugesund district and Trondheimsfjord. On the high fjells there are wild reindeer, glutton, lemming and the now rare arctic fox. The wild reindeer, too, is now very rare in Finnmark, though large tame herds are kept by the Lapps. The lemming is noted for its curious irregular migrations; at such times vast numbers of these small animals spread down country, even swimming lakes and fjords. They are pursued by beasts and birds of prey, and even the reindeer kill them for the sake of the vegetable matter they contain. Hares and red fox are common all over Norway up to the snow line, and badger and hedgehog also occur in the south and southeast. The beaver, formerly widespread, began to decrease in the mid-18th century, but in the [illegible] that protection was introduced and this has saved it. It occurs only in a few of the southern valleys.

Game birds are abundant in most districts. Black grouse are widely distributed south of Finnmark. Hazel grouse are found mainly in the spruce forests of the southeast and east and fairly generally in the north, as are capercaillie which are ... near certain fjords. Woodcock and snipe are moderately ... The partridge, an immigrant from Sweden, occurs princ... the east and southeast. A very large proportion of the No... avifauna consists of migratory geese and ducks, various ... prey, golden plover, etc. These birds leave in autumn by ... well-defined routes—one from Finnmark into Finland ... Dissenters number about 135,00... half comprise members of the Lutheran Free Church, M... Baptists and Pentecostals. The Salvation Army has ... philanthropically since the 1890s.

4. Culture.—The Norwegians are well educated ... read in their own and in foreign literature. The overseas ...

[illegible] mercantile nation have long enriched their culture. In some [illegible] of government and welfare services Norway has led other European countries; women were enfranchised in 1907. The larger towns support one or more theatres and broadcasting services reach a good standard.

The struggle with the harsh, hostile, and sometimes untamable [illegible]ent has engendered a virile, imaginative and independent [illegible] within Norway, and has caused many migrations from its shores. Norway has produced explorers of the calibre of Fridtjof Nansen, Roald Amundsen and Thor Heyerdahl, and many fine seamen. The beauty of the mountains, fjords and shores is outstanding and well appreciated by Norwegians. The majority of the urban population have leisure cottages and cabins in these areas. They are owned or shared by all income groups and are an important factor in Norwegian life. High urban living standards, with a rural population thinly spread over a large and rugged country demand a constant effort by Norway's 3,700,000 people. Men and women work hard in both town and country and recreation is often also strenuous. Mountain walking is a common pastime; there are more than 200 youth hostels and the Norwegian touring club has about 40 huts and 45,000 members. The Association for the Promotion of Skiing, the major Norwegian sport, has about [illegible],000 members. (MA. D.)

III. HISTORY

A. PREHISTORY AND EARLY HISTORY

Stone and Bronze Ages.—The earliest traces of man in Norway are to be found in the far north, along the coast of Finnmark, [illegible] the west north of Stadlandet. Only primitive stone implements have been discovered, and the material is too scanty to supply evidence of when the people using these tools settled in these districts. The coastal fauna provided a means of livelihood for [illegible] fishermen and hunters, and migrants from Russia and Finland may have made their way south along the Norwegian coast [illegible] 7000 B.C. when the interior was still covered with ice, but [illegible] has also been advanced that these peoples came from [illegible] and followed the coast northward considerably later.

In the south of the country dwelling sites have been found dating [illegible] about 5000 B.C. Finds from these sites, which include [illegible] and stone tools from the entire coast, give a clearer idea [illegible] life of the hunters and fishermen. The implements vary [illegible] shape and are made of different kinds of stone; those of later [illegible] are more skilfully made. Rock carvings have been found, [illegible] near hunting and fishing grounds. They represent game [illegible] deer, reindeer, elk, bears, birds, seals, whales and fish, [illegible] for the survival of the coastal peoples.

Between 3000 and 2500 B.C. new migrants settled in eastern [illegible]. They were farmers who grew barley and kept cows and [illegible]. The hunting-fishing population of the west coast was also [illegible] replaced by farmers, though hunting and fishing remained useful secondary means of livelihood.

From about 1500 B.C. bronze was gradually introduced, but the [illegible] of stone implements continued; Norway had little riches to [illegible] bronze goods and the few finds consist mostly of the [illegible] weapons and brooches which only the chieftains could [illegible]. Large burial cairns built close to the sea are characteristic [illegible]. The motifs of the rock carvings differ from those [illegible] age. Representations of the sun, animals, trees, [illegible] and men were all now strongly stylized, probably as [illegible] connected with the religious ideas of the period.

[illegible] Age (500 B.C.–A.D. 1050).—Little has been found dating [illegible] the early iron age (the last 500 years B.C.). The dead [illegible] cremated and their graves contain few burial goods. During [illegible] centuries A.D. the people in Norway were in contact [illegible]-occupied Gaul. About 70 Roman bronze caldrons, [illegible] as burial urns, have been found. Contact with the [illegible] countries farther south brought a knowledge of runes. [illegible] known Norwegian runic inscription dates from the 3rd century (see RUNE). At this time the settled areas in the country [illegible], a development which can be traced by a study of place [illegible]. The oldest root names such as *nes*, *vik* and *bø* (cape, [illegible] and farm) are of great antiquity, dating perhaps from the Bronze Age, while the earliest of the groups of compound names with the [illegible] or [illegible] Bergen, Sarheim, [illegible] date from the first centuries A.D.

The period of the collapse of the Roman empire in the west (A.D. 400–600) [illegible] weapons and gold [illegible]. Hill forts were built on precipitous rock [illegible] defense against [illegible] tribes from the south. Excavation has revealed the stone foundations of farmhouses 60–90 ft. long (one even 150 ft. long), the roofs of which were supported on wooden posts. These houses were family [illegible] where several generations lived together, men and cattle under one roof. From this period and later (600–800) nascent communities can be traced. Defense works presuppose co-operation and leadership, so that petty states of some kind with a defense and administrative organization must have existed.

These states were based either on clans or tribes, *e.g.*, the Hørder of Hordaland in western Norway. By the [illegible] century these small states had assemblies (*thing*), where yeomen, free men who owned their farms, settled disputes in accordance with agreed laws. The small states or *fylker* (counties) were divided into smaller districts each with a *thing*. The larger *thing* united to form even larger units, assemblies of yeomen's representatives from the various regions. In this way the *lagting* (lawmaking assemblies) developed—the *Gulating* in the west, the *Frostating* in Trøndelag and the *Eidsivating* in the east. These had come into existence by about the year 900. The *thing* meeting place and the *hov*, the heathen temple, were usually situated on the best and oldest farms belonging to the chieftains and the wealthiest farmers.

The Vikings.—The years 800 to 1050 were those of the Viking (*q.v.*) age, when Scandinavians set out on innumerable plundering expeditions abroad. Surplus population, superior ships and weapons, well-developed military organization and a spirit of adventure seem to have combined to cause this great movement. The Norwegians mostly sailed westward, raiding and settling in Ireland, Scotland, England, France, the Shetlands, Orkneys and Hebrides, the Isle of Man and in the unpopulated Faeroe Islands and Iceland. Men of Norwegian descent settled in Greenland and undertook expeditions to Vinland (the northeast coast of America). Many Vikings returned home and this meeting with western Europe was decisive for the development of Norway.

B. MEDIEVAL NORWAY

Knowledge of the exploits of many heroes of the Viking age is derived from the scaldic poetry (*see* ICELANDIC LITERATURE) and from chronicles, such as the Anglo-Saxon Chronicle, written in the countries the Vikings raided or in which they settled. For the history of Norway [illegible] the work of the [illegible] the two centuries following the Viking age provided important sources [illegible] saga writers [illegible] Snorri Sturluson (d. 1241) whose *Heimskringla* provides biographies of the kings up to 1177. These sagas and the oldest known written records, laws and official documents date from the 12th and 13th centuries and throw light on the important period when the country was achieving political entity.

Formation of a United Norway (900–1035).—The force that lay behind the Viking expeditions [illegible] the formation of larger states in Norway. [illegible] strong enough to repel Viking [illegible] the chieftain [illegible]. To maintain his [illegible] he had to [illegible] territory.

By A.D. [illegible] the [illegible] of Lade [illegible] under his dominion an area [illegible] Trøndelag and [illegible] Hålogaland, now Nordland, the land so far north as Norwegians had settled—Ottar or Ohthere who visited King Alfred [illegible] in England was from the northernmost district. [illegible] in the country other chieftains and jarls ruled over territories of varying size. The Danish king owned [illegible] the land around [illegible] but Vestfold, the territory west of the [illegible] was [illegible] by powerful Norwegian chieftains. At [illegible] and at [illegible] in Vestfold are the sites of two large [illegible] a great variety of rich equipment has been found dating from this period

By that time, too, members of the Yngling dynasty had been ruling as kings in Vestfold for perhaps 150 years. Harald I Haarfager or Fairhair (d. *c.* 940), son of Halvdan the Black in Vestfold, carved out for himself a state in western Norway, decisively defeating his opponents at Hafrsfjord (near Stavanger) in a battle traditionally dated 872 but which probably took place *c.* 900. To posterity Harald stands as the man who united Norway, but he probably had effective control only in the west. Along the south coast and perhaps in the east he had some sort of nominal authority.

Harald's son Eric (Eirik) Bloodaxe (d. 954) quarreled with the chieftains and with his brothers and had to leave the country (*c.* 945), eventually becoming king of York, in England. He was replaced by Harald I's youngest son Haakon I the Good (d. *c.* 960), who had grown up at the court of Aethelstan in England. Haakon contented himself with the westcountry kingdom. He persuaded the yeomen to agree to the *leidang*, a system by which they themselves raised ships and crews for the king's use. Haakon fell fighting Eric's sons, of whom the eldest, Harald II Graafell or Graycloak (d. *c.* 970) subsequently gained control of the jarl of Lade's territory so that the whole coast from Haalogaland southward to Agder was united. But the jarls of Lade had not been finally subjugated and they continued to contest their territory with the descendants of Harald I well into the 11th century. The loser generally appealed to the Danish king who wanted to secure his position in the east.

In the late 10th century, the Vikings again attacked England. Among them were two descendants of Harald I, the future kings of Norway Olaf I Trygvesson and Olaf II Haraldsson, who both won wealth (danegeld) for themselves. On their wanderings they were converted to Christianity, and in Norway both tried to convert their subjects. Olaf I (reigned 995–1000) fell in battle against Sweyn I of Denmark and Eric, jarl of Lade. Olaf II (1015–30) conquered the Danish territory in the east and was thus the first king of all Norway. In the consequent clash with Canute, king of both Denmark and England, whom many Norwegian chieftains joined, Olaf was forced to flee to Russia (1028). On his return he fell in battle at Stiklestad (1030). Miracles were reported directly after the battle, Olaf was immediately reputed a saint and his body was enshrined in 1031. After Stiklestad Canute placed Sweyn, his son by his Anglo-Saxon mistress Aelfgifu, on the Norwegian throne. But Sweyn got no help from abroad and left the country, the saint's son Magnus the Good succeeding him in 1035.

Both Olafs brought with them missionaries from England, but it was Olaf II who first organized the work of conversion. He built churches and, advised by the Anglo-Saxon bishop Grimkell, drew up a church law which the yeomen ratified at the *thing*. The Anglo-Saxon missionaries trained Norwegians as priests. As a result church organization and ecclesiastical law in Norway, caligraphy and to some extent the earliest written Norwegian were all based on Anglo-Saxon models. By posterity St. Olaf has been regarded above all others as the lawgiver both for the church and the state, the two most potent institutions for the establishment of peace and order in the community (*see* also OLAF).

It is not known exactly how the *thing* administered and enforced the law. Men who were able to expound the law at the *thing* acquired special authority. By the 12th century they were called *lagmenn* (lawmen) and were drawn from among the yeomen themselves. The only punishments were fines and banishment. At first the king's influence was largely dependent on his presence so that he was constantly traveling about the country. But since punishment presupposed a central authority able to enforce sentences, the crown gradually extended its power.

Magnus I to Sigurd I (1035–1130).—Canute's empire disintegrated after his death in 1035. Peace was negotiated between the rivals Magnus I the Good (1035–47) and Canute's son Hardicanute so that after Hardicanute's death (1042), Magnus became king of Denmark. His position was challenged, however, and Harald III Hardraade or Hardruler (d. 1066), a half-brother of St. Olaf, who from 1046 shared the kingdom with Magnus, had to yield up Denmark. Harald, who had been in the service of the emperor Michael IV at Constantinople, controlled the chieftains rigorously. He set out with the Anglo-Saxon earl Tostig on a campaign against England and fell at Stamford Bridge in 1066 (*see* ENGLISH HISTORY).

Of the kings who followed, the brothers Magnus (1066–69) and Olaf III Kyrri or the Quiet (1066–93), Magnus II Barfot or Bareleg (1093–1103) and the brothers Eystein I (1103–22) and Sigurd I Jerusalem-farer (1103–30), only Magnus II was an active warrior. In two campaigns he subdued the Hebrides and the Isle of Man, fought in Wales and finally fell in battle in Ireland. Within Norway this was a period of peace and order. *Lendmenn* (royal thegns holding land from the king) and *aarmenn* (royal officials) managed the royal estates, collected fines and punished raiders and thieves. The king obtained some revenue from oversea trade, selling abroad fish, furs and walrus teeth from Greenland. The main trading centres were Bergen, Nidaros (Trondheim) and Oslo.

The Age of Civil Wars (1130–1240).—Before the death of Sigurd I, Harald IV (1130–36), a son of Magnus II, arrived from Ireland, claimed the throne and fought against Sigurd's son Magnus III the Blind (1130–39). Later others appeared saying they were kings' sons, and at that time all the king's sons, legitimate or illegitimate, had an equal claim to the throne. As these pretenders were each supported by some of the magnates, there was constant fighting. But few of the farmers were involved in these struggles and the work of establishing the church continued unhindered.

Originally the Norwegian church came under the archbishopric of Bremen and from 1104 under Lund, then part of Denmark. In 1152 the English cardinal Nicholas Breakspear (later Pope Adrian IV) went to Norway to establish at Nidaros a metropolitan see, the province of which was to comprise 11 bishoprics, 5 in Norway and 6 in the areas where Norwegians had settled in the Viking age. The western isles were under the nominal suzerainty of the Norwegian crown and Iceland and Greenland were economically dependent on the connection with Norway. The cathedral built at Nidaros was the largest and most magnificent cathedral in the north. Monasteries had been established in Norway in the first half of the 12th century and the church obtained a regular income from tithes.

The ecclesiastics were then sufficiently established to assist in extending the king's authority. In 1161, with the support of the church and of the magnates, Magnus IV Erlingsson (1161–84), the five-year-old son of Sigurd I's daughter, was chosen as king despite the fact that he was not a king's son. But he was legitimate and after his coronation (1163) he called himself "king by the grace of God," and affected to hold his kingdom as the vassal of St. Olaf, thus symbolizing the association of crown and church. The promoters of this alliance, Magnus' father, Erling Skakke or the Crooked and Archbishop Eystein (*q.v.*) also arranged the succession after Magnus; in the future the king's eldest legitimate son was to ascend the throne.

From then on the country's leading men, both lay and clerical, the royal officials and representatives of the yeomen were summoned on important occasions to take part in a great council. *Sysselmenn*, officials appointed by the king, were responsible for ruling the various districts and at the *thing* the *lagmenn*, then holding office from the crown, gradually took over judicial functions. The people's obligation to raise the *leidang* (army) was at length converted in peacetime into the first tax levied by Norwegian rulers.

Claimants to the throne still appeared. The most dangerous was Sverre (1177–1202), brought up in the Faeroe Islands and ordained priest. Both Erling and Magnus IV fell fighting against Sverre, who by 1184 was unchallenged king. He quarreled, however, with Archbishop Eric Ivarsson who in 1190 fled the country. The king was excommunicated and his enemies combined against him, peace between church and state being reestablished only after his death. Sporadic struggles continued, however, until 1240, when the last claimant to the throne was killed.

The Period of Greatness (1217–1319).—During the civil wars there had been long intervals of peace and the authority of the crown was steadily strengthened. From the time of Haakon IV

Haakonsson (1217–63) there was only one king in Norway and he wielded considerable power. From then onward a conscious attempt to organize the king's council and establish an efficient central government can be traced.

As undisputed king, Haakon IV had larger revenues than his predecessors. He used them to increase the splendour and prestige of the monarchy and to raise Norway culturally to a European level. He was crowned in 1247 by a papal legate and, copying English models, built in Bergen a royal hall of stone (Haakonshallen). He also showed great interest in literature, encouraging the translation into Norwegian of chivalric romances. *Konungs skuggsjá* ("The King's Mirror," *c.* 1250), a guide to conduct for princes which also throws light on the ideals and theories of the time, is a more original work. Haakon exchanged gifts and corresponded with the princes of other countries. He was on friendly terms with Henry III of England, which led in 1217 to a treaty of friendship and a commercial treaty by which Norwegian and English merchants could enter each others' country freely. This is the oldest commercial treaty known in the history of either country. On several occasions Haakon was granted the right to buy grain when its export from England was otherwise forbidden.

From 1250, when Haakon concluded a treaty with Lübeck, the German towns gradually acquired a dominating commercial position in Norway. Germans settled in the country, especially in Bergen, competing with the natives so successfully that they became a problem for both crown and city. But the Norwegians had become so dependent on the import of German grain and other goods that neither Haakon nor his successors could do more than attempt to limit the activities of German merchants.

Bergen was an entrepôt port for wares from abroad which were reexported to Iceland and Greenland. Iceland was torn by feuds in which Haakon intervened, with the result that in 1262 the Icelanders agreed to accept his suzerainty on condition that he enforced the peace and ensured the annual arrival in Iceland of six shiploads of merchandise. The settlers in Greenland had accepted (1261) the same conditions, the king agreeing to maintain regular communications between Greenland and Norway.

In 1262 Alexander III of Scotland, who had already tried to persuade Haakon to cede the western islands, attacked Skye and seemed about to invade the Hebrides. So Haakon sailed out to defend the Hebrides and Man (1263); but he had to give up the campaign and died on the Orkneys. By the treaty of Perth in 1266 Magnus V Lagaboeter or Lawmender (1263–80) ceded the Hebrides and Man to the Scots in return for an annual rent.

Magnus V is best known for his gradual replacement of the old regional laws by a national code, based mainly on the systems then in existence. These new laws ran everywhere except in the towns, which received their own code. These codes remained the law of the realm for more than 400 years. A new church law was drawn up by Archbishop Jon and an agreement to secure peaceful relations between church and state was worked out. The financial advantages then gained by the church led, after Magnus' death, to trouble between the archbishop and the regents governing on behalf of the young king Eric II (1280–99). The church was forced to give them up but retained the right to try spiritual matters in the ecclesiastical courts. Eric married (1281) Margaret (d. 1283), daughter of Alexander III, and was the father of Margaret (the Maid of Norway), heiress to the Scottish throne. He married (1293), as his second wife, Isabella, sister of the future Scottish king Robert I the Bruce.

German merchants and craftsmen became more and more noticeable in Bergen. In 1294 the Hanseatic cities secured exceptional commercial privileges in Norway, escaping nearly all the obligations and dues laid upon Norwegian merchants. From the time of Haakon IV the king had usually resided in Bergen, but as the royal revenues from trade declined and contact with the western isles dwindled, the eastern part of Norway became more important to the monarchy and foreign policy more concerned with Sweden and Denmark. Trained knights in armour were then superseding the *leidang* fleet as the basis of warfare. Eric's brother Haakon V (1299–1319) lived in Oslo where he built a fortress (Akershus). Haakon V kept a close hand on the administration of the country and, following French and English models, instituted a check on the activities of local officials.

Scandinavian Politics (1319–97).—In the middle ages, in Norway as elsewhere, the most important source of wealth was land. It has been calculated that about the year 1300 the king, the great men and the church together owned more than half the landed estates in Norway, and the independent farmers rather less than 40% of the cultivable land. The farmers paid tithes to the church, *leidang* tax to the king and often rent to the landowner, all of which had to be paid either out of what the farm produced or in fish. The ruling classes were therefore dependent on the farmers' efforts, so that when in 1349 the Black Death reached Norway from England and killed both rich and poor the country's economic foundations collapsed. It is estimated that between one- and two-thirds of the population died during the plague, but even the lower figure must have been catastrophic for so thinly populated a country. When the farmers left their farms or were unable fully to cultivate them, not only they, but also king, church and nobles lost the means of livelihood. The whole country became desperately poor and it took centuries for this economic regression to be overcome; this is one important reason why Norway failed to assert its own policy and to maintain its independence.

In the 14th century it became difficult for members of the few great families to find suitable marriage partners in Norway, with the result that Swedish noblemen often became the owners of large Norwegian estates. The royal family also looked to its neighbours for partners; Haakon V, who had no sons, married his daughter Ingeborg to a Swedish prince. Their three-year-old son Magnus VI Ericsson became king of Norway (1319–43) and of Sweden (1319–1363). The union of the crowns did not at first affect the government of the two countries. Most of the time while Magnus was a minor, a regency governed in Norway, and another was set up when Magnus gave up the Norwegian throne in favour of his younger son, the three-year-old Haakon VI (1343–80), but when Haakon came of age he began to rule Norway himself and also parts of Sweden in conjunction with his father.

Haakon VI chose as his queen, Margaret, daughter of Waldemar IV of Denmark, and their only son Olaf IV became king of Denmark (1375–87) and Norway (1380–87). He died at the age of 17, and was the last of the old royal lines in all three Scandinavian countries. Margaret, while taking over officially the government of both Denmark and Norway and a little later that of Sweden, worked for the union between the three Scandinavian countries which was ratified at Kalmar in Sweden when Eric of Pomerania (1397–1442) was crowned king of Denmark, Sweden and Norway.

(C. Jo.)

C. Danish Rule

Eric of Pomerania continued Margaret's unitary policy, with the consequence that, since support for the crown came primarily from Denmark, lands, offices and sees throughout Scandinavia were generally assigned to Danes. National resentment at this led to Engelbrekt Engelbrektsson's rebellion (1434) in Sweden, which was followed by two Norwegian peasant risings in the Oslo district under Amund Sigurdsson in 1436 and under Hallvard Graatopp in 1438. But the Danish nobility itself then turned against Eric, who was deposed in 1439, and Norway came to accept his nephew and successor Christopher of Bavaria (Christopher III of Denmark) as king in 1442. Henceforth till 1814 the Danish kings ruled Norway (*see* Denmark: *History*). The Norwegian fleet and army decayed, and Norway's written language gradually gave place to Danish; Germans plundered its coasts and monopolized its commerce, and after 1450 Danes began to appropriate the higher administrative posts. When in 1448 Karl Knutsson (Charles VIII) was chosen king by the Swedes and Christian of Oldenburg by the Danes, it was by force that Norway fell to the latter. The Norwegians protested, and in some districts Karl Knutsson was recognized as king, but the next year the Swedes assented to the separation. Christian I (1450–81) gave Norwegian estates and offices to his Danish subjects and Norway's ancient possessions, the

Orkneys and Shetland Islands, to the king of Scotland as security for a dowry which remained unpaid. His son John (Hans; 1481–1513; jointly recognized by Denmark and Norway in 1483) purchased the obedience of the Norwegian nobles by concessions to their power and by limitation of the trade privileges of the Hanseatic league. The imposing union continued in name, but the weakness of the nation and its government had been strikingly illustrated in 1455 when the Germans in Bergen besieged a monastery in which a high official had taken refuge and killed the official and a bishop.

After the exile and imprisonment of Hans's son Christian II (1513–23) the position of Norway was changed for the worse; the Norwegian council of state was abolished in 1536, and the country was ruled for a century and a quarter by Danish officials. Its churches and monasteries were sacked by Danes, and Danes were installed as pastors after the Reformation, which the Norwegians were compelled to accept in 1539. Soon Norway was dragged by Denmark into the Seven Years' War of the North (1563–70) against Sweden. However, the power of the Hanseatic league in Bergen had been finally broken during the reign (1534–59) of Christian III. The rule of the Oldenburg dynasty proved neglectful rather than tyrannical, and under it the mass of the peasants was not flagrantly oppressed. Christian IV (1588–1648), who founded Christiania (Oslo), may almost be said to have discovered Norway anew. He reformed its government, reorganized its defense and strove to develop its resources according to the principles of mercantilism, but his foreign policy involved the loss of Jemtland (Jämtland) and Herjedalen (Härjedalen), which were ceded to the Swedes by the peace of Brømsebro (1645). The Danish war of revenge against Charles X of Sweden resulted in further loss by Norway. Trondheim and Baahuslen (Bohuslän) were ceded by the peace of Roskilde (1658) and although the former was restored by the peace of Copenhagen (1660) the Norwegian population fell possibly below 450,000. From the middle of the 17th century, however, the Dutch and English made their influence felt, and the political status of Norway could no longer be regarded as a purely Scandinavian affair. The establishment of hereditary autocracy in Denmark by Frederick III in 1660 conferred some benefits upon Norway, such as better government control over the local officials and a more just system of taxation. The Norwegian peasant remained a freeman while his counterpart in Denmark was a serf. Norwegian law, already recodified by Christian IV, was again revised under Christian V (1670–99), who was well served by the Norwegians in his unsuccessful attempt to regain the lost provinces from Charles XI of Sweden.

Under the sons of these monarchs, Frederick IV of Denmark and Charles XII of Sweden, Norway was once more compelled to pay for Danish warfare against Sweden (the Great Northern War). Norwegian shipping, which had experienced a sudden boom in the 1690s, was severely depleted, partly because of the renewed war from 1709, and in 1716, when driven from continental Europe, Charles XII attacked Norway. Only his death, in 1718, averted the danger. During this war Peder Wessel, the greatest among a long series of Norwegian heroes who served in the Danish fleet, won undying fame: in 1716 he was ennobled under the name of Tordenskjold. Before the close of the 18th century increasing prosperity developed the national consciousness of Norway. The extensive cultivation of more land, the growth of the mining industry and especially of the timber trade with England gave rise to a great increase in wealth and population. In a century and a half the number of the Norwegian people was doubled, so that by 1814 the population was about 900,000. In 1788 the oppressive law (imposed in 1735) that grain should be imported into southern Norway only from Denmark was repealed. Due moreover to the Scandinavian policy of neutrality, Norway actually drew financial profit from the wars of the French Revolution.

In 1770 freedom of the press was introduced temporarily by the reforming zeal of the German doctor Johann Friedrich Struensee, who exercised at that time a more real power in Denmark-Norway than did his insane master Christian VII (1766–1808). The national aspirations of Norway were then at once voiced, though at first they went little further than the demand for a Norwegian university, which was to be conceded by Frederick VI in 1811. The crisis destined to break the union did not develop until 1807, when the coup against the Danish fleet, planned by the British foreign secretary, George Canning, drove Frederick, the crown prince regent, to abandon neutrality and to support Napoleon. Norway suffered great and immediate damage from a British blockade and was more or less cut off from Denmark, so that a separate administrative commission had to be set up. In 1809 the head of this commission, Prince Christian Augustus of Augustenburg, was elected by the Swedes as heir to Charles XIII of Sweden in pursuance of a plot, originated by the Norwegian national leader, Herman Count Wedel Jarlsberg, to transfer the allegiance of Norway to that country. Christian Augustus, however, relinquished his connection with Norway immediately after his election and the scheme was finally frustrated by his death in May 1810, whereupon the choice of Sweden fell upon Napoleon's marshal Jean Bernadotte, in the hope that so distinguished a soldier might recover Finland (taken by Russia in 1808–09). But Bernadotte was too wise to attempt this and planned to annex Norway instead. With this object he forced Frederick VI, by the treaty of Kiel (Jan. 14, 1814), to renounce his sovereignty over Norway in favour of the king of Sweden. In return for his help against his former master Napoleon, the allied great powers had given their support to Bernadotte's policy.

D. Union With Sweden, 1814–1905

The treaty of Kiel was, however, immediately repudiated by the Norwegians, who claimed the right to determine their own sovereignty. The leader of this independence movement was the viceroy Christian Frederick, who was heir to the Danish throne and hoped later on to be able to restore the Dano-Norwegian union. A representative assembly, convened at Eidsvoll, prepared and adopted on May 17, 1814, a national constitution based on the democratic models of the U.S., France (1791) and Spain (1812) and unanimously elected Christian Frederick as king of Norway. A Swedish invasion followed, but negotiations were almost simultaneously opened, and it was agreed that Norway should retain its independence and its new constitution, subject to a merely personal union under the Swedish king. Christian Frederick abdicated and left the country, and the terms drawn up in the convention of Moss (Aug. 14) were ratified and worked out in detail by an extraordinary *storting* (national legislative assembly) in November.

Reign of Charles XIV John (1818–44).—The settlement thus reached held from the first the seeds of conflict and misunderstanding. Even Bernadotte, who succeeded to the dual monarchy as Charles XIV John on Charles XIII's death in 1818, believed that circumstances would soon bring about the complete amalgamation of Norway and Sweden, as he had originally planned—a view rendered plausible enough by the poverty and trade depression in Norway which followed the end of the Napoleonic wars. Swedish opinion generally continued to regard Norway as a conquered country and the treaty of Kiel as the title deed to it. Such an attitude naturally made the Norwegians more than ever determined to guard and to emphasize their newly won independence. Moreover, the national constitution, based on Montesquieu's theory of complete separation between executive, legislature and judiciary (*see* Montesquieu, Charles Louis de Secondat), promoted conflict rather than collaboration between the first and second of these powers. The king, as head of the executive, controlled among other things the foreign affairs of both his kingdoms, on which he was advised by a Swedish foreign minister; and his Norwegian councilors were excluded from membership or even from attendance in the legislature. Thus, while the *storting* grew increasingly democratic, executive power still rested with a bureaucracy appointed by the crown. The king was principally resident in Sweden and was represented in Norway by a *statholder* or viceroy who was, until 1829, a Swede. Swedish influences predominated in all questions where the interests of the two countries differed.

Such a case arose in the "Bodø case" of 1818–21, when an English merchant who had been arrested on charges of smuggling and other irregularities succeeded, through British diplomatic pressure on the king and his Swedish advisers, in securing heavy damages

which the Norwegian government was reluctantly compelled to pay. But even earlier the inevitable conflict had begun. When the Norwegian *storting* passed a bill (1815 and again in 1818) for the abolition of titles of nobility, the king at once exercised his constitutional right of veto and only reluctantly sanctioned the bill on its being passed by a third successive *storting* (1821). A further dispute arose over the settlement with Denmark of Norway's share in the joint national debt of the two countries. Charles XIV John, with British mediation, concluded in Sept. 1819 a convention with Denmark, by which Norway was made liable for no more than 3,000,000 *riksdaler*. These terms, however, were only tardily accepted by the *storting* and the delay made the king doubt the Norwegians' sincerity and, apparently, contemplate a *coup d'état*. In July 1821 he assembled a force including 3,000 Swedish troops near Christiania (Oslo), ostensibly for maneuvers, having previously circularized the powers (June 1) with a note courting their sympathy for an attempt to force a revision of the constitution. Induced to abandon this idea, he submitted his proposals for revision to the *storting*, which, however, unanimously and repeatedly rejected them, thus coming to be regarded as the defender of the constitution against a would-be autocrat.

Trouble also arose over the king's attitude to the celebration of May 17 (on which day Christian Frederick had become king) as the anniversary of Norwegian independence, which he considered as a demonstration of disloyalty toward himself. His attempts to prohibit these celebrations culminated in 1829 in the *torvslag* or "battle of the market place," when an inoffensive gathering, which included women and children, was charged by soldiers on the orders of the Swedish viceroy. No one was wounded.

In addition to these conflicts between the executive and the legislature, an antagonism soon developed in the *storting* itself between the views of representatives of the old governing class and the growing democratic aspirations of the peasantry. The constitution of 1814 granted parliamentary suffrage to the peasants who owned their land or had rented it for five years and to the urban middle class. Nevertheless, for some time afterward political power remained in the hands of the old official class, from which the majority of the candidates for the *storting* were taken. The seeds of democracy, however, began to germinate after the "July revolution" in France and the similar disturbances throughout Europe (1830). From 1833 the peasant representation in the *storting* increased in number and acquired a competent leader in Ole Gabriel Ueland, and an opposition consisting of peasants and city liberals developed to challenge the supremacy of the bureaucracy in the legislature as well as in the executive. The first important victory for democracy was won in 1837, when, after considerable difficulty in obtaining the royal assent, the local government of the country was placed on a popularly elected basis—a measure which contributed more perhaps than anything else to awaken and educate the political consciousness of the general population.

The tension between the king and the *storting* reached its climax in 1836, when Charles XIV John arbitrarily dissolved the legislature and the latter retaliated by impeaching and fining a minister who had supported the king's decision. From this date to the close of his reign Charles XIV John became more conciliatory, acquiring before his death remarkable popularity with his Norwegian subjects. An important step toward this change was made later in 1836, when the post of *statholder* was conferred on Count Wedel Jarlsberg. Another royal concession was the permission, granted in 1838, for merchant ships to fly the Norwegian flag in all waters, its use having been previously severely restricted. The question of the general use of the national flag was one of the items under consideration by a mixed committee of Norwegians and Swedes at the time of the king's death.

Reign of Oscar I (1844–59).—Charles XIV John's son and successor Oscar I soon showed his desire to meet the wishes of the Norwegian people, decreeing that in all documents concerning the internal government of Norway that country's name was to stand first in the royal title; that Norway and Sweden should each carry its own national flag as the naval flag, with the mark of union in the upper corner; but the mark of union was also imposed on the Norwegian merchant flag.

The condition of the country had considerably improved, and the 1840s and 1850s were marked by important legislative reforms. The old privileges and restrictions in handicraft and trade were modified or abolished. The prison system was reformed and the criminal law was made less harsh. Freedom of religious worship for all Christians and Jews was introduced, although Jesuits, banished since 1624, were still banned from the country. New roads were made, the first railway built (1854), steamship routes established, lighthouses erected and trade and shipping developed. The abolition of the English navigation acts in 1849 and 1854 opened up a great future for the Norwegian merchant fleet. The removal of the English ban on export of machinery in 1843 made it possible to establish the first cotton textile factories and engineering workshops in Norway in about 1850.

However, the lower classes still felt the economic pressure of the rapid growth of population. Emigration to America rose to nearly 4,000 a year in the 1850s and averaged about 15,000 in the later 1860s. In the years 1849–50 the first nationwide labour movement was created by Marcus Thrane who found his strongest support among cottagers, artisans and town workers. But the movement was crushed through legal prosecution, and it was not till the 1870s that the first trade unions were organized.

In the 1850s Sweden and Norway abandoned the pro-Russian foreign policy followed by Charles XIV John. In 1851 Russia demanded for its frontier Lapps the right to fish on the Norwegian coast and to settle upon a portion of the coast of the Varangerfjord. Serious complications might have ensued if Russia had not been diverted by fresh developments in the Eastern question. During the Crimean War (1854–56) King Oscar concluded a treaty with England and France by which these countries guaranteed Norwegian and Swedish territory against Russia (the November treaty, 1855).

Reign of Charles XV (1859–72).—Because of King Oscar's ill-health his son, Crown Prince Charles, was appointed regent in 1857, and in 1859 he succeeded as Charles XV. He desired to inaugurate his reign by giving proof of his willingness to meet Norwegian claims, especially with regard to the problem of the office of viceroy. According to the constitution the viceroy might be either a Norwegian or a Swede. Since 1829 no Swede had held the post, and since 1855 it had been vacant. But the paragraph in the constitution still existed, and the Norwegians naturally wished to have this stamp of "dependency" obliterated. A proposal to abolish the office was passed by the *storting* in 1859. The king had privately promised that he would sanction the proposed change in the constitution; but when a violent outcry arose in Sweden, he refused his sanction.

In 1860 the Swedish government pressed for a revision of the Act of Union with the purpose of strengthening the institutional bonds between the two countries and of codifying the actual supremacy of Sweden in the union. Because of a strong resolution of the *storting*, based on the work of a special committee, the Norwegian government rejected the proposal, but its members disagreed over the form of the reply. The more obstinate among them resigned, and others, of a more pliable nature, were appointed; their leader was Frederik Stang, who had been minister of the interior from 1845 to 1856, and who hoped to bring about a better understanding between Sweden and Norway. This cause was aided by the king's advocacy of a revision of the Act of Union designed to inaugurate a real equality between the two countries. It was also strengthened by the growth of pan-Scandinavian sentiments in Norway, partly stimulated by fear of Germany. In 1865 a second union committee was appointed and its report was published in 1867. But opponents to the government soon showed that the new draft would emphasize the supremacy of Sweden and would considerably strengthen the union. The Stang ministry accepted it, but it was rejected by an overwhelming majority in the *storting* in 1871.

While the union movement was being fought, pan-Scandinavian sentiment had declined. Denmark's troubles over Schleswig-Holstein (1863–64) had threatened to draw Sweden and Norway into war on Denmark's side. At that time King Charles favoured a defensive alliance with Denmark, but the majority of the *storting*

would only consent if an alliance could also be effected with at least one of the western powers. As this was not achieved, the Danes were left isolated and their defeat in 1864 spread disillusion among the advocates of Scandinavianism in Norway and Sweden.

In 1869 a resolution was passed making the sessions of the *storting* annual instead of triennial. Its passage marked the final alliance between two opposition groups: the Peasant party led by Søren Jaabaek, and the city radicals, mostly lawyers, under the leadership of Johan Sverdrup. Thus was founded (although not yet formally organized) the great national democratic (liberal) party of the Venstre (the Left). In the *storting* they formed a strong majority which in 1872 carried a bill proposing that ministers should be admitted to the *storting* and should take part in its proceedings. In the preceding half century the government party had several times introduced a similar bill, but the opposition had feared lest the superior skill and experience of the ministers would give them undue influence. The opposition by that time had gained more confidence in its own strength, and Johan Sverdrup, at least, regarded the admittance of the ministers to the *storting* as a step toward full parliamentary government. But, on the advice of the Conservatives under Stang, the king refused his sanction and even insisted that the ministers should stay in office in spite of the *storting*'s vote of censure against them.

Reign of Oscar II (1872–1905).—In Sept. 1872 Charles XV was succeeded by his brother Oscar II, who in 1873 sanctioned the abolition of the office of viceroy, the president of the ministry being thenceforward recognized as the prime minister. Because of this change the *storting* had to alter the wording of the bill that was constantly brought up to propose the admittance of the ministers. It was again passed in 1874, 1877 and 1880, but the king steadily refused his sanction. In defiance of this veto the *storting* resolved (June 9, 1880) that the bill should be declared to be the law of the land, but the king and his ministers declared the resolution invalid. The prime minister, Stang, then resigned and was succeeded by Christian August Selmer, a firm Conservative who was intent on continuing the conflict, and the antagonism between the government and the *storting* increased. Not even after the sweeping victory of the Left at the elections in 1882 did the ministry and the king show any sign of yielding, and in Feb. 1883 the *odelsting* (the lower division of the national assembly) decided to impeach the whole of the ministry for having acted contrary to the interests of the country by advising the king to refuse his sanction. After ten months' trial, the *riksrett* (a court where the majority of the judges are taken from the *lagting*, the upper division of the *storting*) in 1884 sentenced Selmer and seven of his ministers to be deprived of their offices, while three were heavily fined. Selmer advised the king to ignore the judgment, and Oscar II had in fact had plans of a *coup d'état*, but after some hesitation he yielded, not least because he lacked the support of his Swedish government. However, in his declaration that the judgment would be carried into effect, he upheld the constitutional prerogative of the crown, and asked one of the ministers who had been fined to form a ministry. This ministry was a failure, and after another attempt to get a "ministry of reconciliation," the king was at last compelled to appoint Johan Sverdrup. Thus the first Left ministry in Norway came into being (June 1884). In the same year the two parties, the Left and the Right, became organized on a national scale, and the latter soon accepted the principle of ministerial responsibility to parliament although it has never been codified in the constitution.

The Struggle for Separate Diplomatic Representation and the Achievement of Independence.—During the years of the Sverdrup ministry (1884–89), some important reforms were achieved; trial by jury was introduced and the elementary school system was reorganized. The Left, however, was soon split, partly over a question of church reform. Sverdrup lost his absolute majority in the elections of 1888, resigned in 1889, and a Conservative ministry was formed by Emil Stang, the son of Frederik Stang. This was defeated in 1891 on the "Diplomatic question." The Norwegians wanted equal representation with Sweden on the special joint council handling foreign affairs (the ministerial council of state); after 1885 the Swedes were willing to grant this numerical equality, but only provided that the joint minister of foreign affairs should continue to be a Swede, and this the Norwegians would not accept. In 1891, after the *storting* had virtually censured its negotiations with the Swedes, the Stang ministry resigned, and a Left ministry under Johannes Steen was appointed. The Left then adopted a determined line of action in the union question, and the *storting* in 1892 and 1893 passed resolutions for the establishment of a separate consular service for Norway; but the king refused his sanction; the Left ministry therefore resigned in 1893, and Emil Stang formed a minority Conservative ministry. He gained no adequate support in the elections in 1894, and his ministry resigned in 1895. The Swedes then resorted to drastic measures and doubled their defense budget. On June 7, 1895, the *storting* yielded and ceased to press for a separate consular service; shortly afterward a coalition government was formed, with the conservative Georg Francis Hagerup as prime minister. A new committee of Norwegians and Swedes spent more than two years in fruitless labour on the question of separate diplomatic representation. At the elections in 1897 a stronger Left majority was returned, and in 1898 Hagerup was replaced by Steen. The appropriations for the defense were raised considerably during those years; another expression of the national feelings was the adoption, after bills for the purpose had been three times vetoed, of the "pure" Norwegian flag in 1898. In the same year universal political suffrage for men was passed. Women received local government franchise in 1901 and a restricted parliamentary suffrage in 1907. Universal political suffrage was extended to them in 1913.

The rising government expenditure caused by armaments and various social reforms was made possible by the rapid economic progress in the 1890s and by the introduction of state income tax in 1892 (made progressive in 1895). A fraction of the Left were, however, opposed to this development, and joined with the Right in a broad, conservative "consolidation party," which gained the majority at the elections in 1903. Hagerup formed another coalition ministry, and hoped to be able to settle the question of a Norwegian consular service on the basis of a Swedish-Norwegian agreement of March 24, 1903. Then suddenly, in Nov. 1904, the Swedish prime minister, E. G. Boström, submitted to Norway new conditions for the establishment of separate consuls. These conditions were almost unanimously considered unacceptable, and the Norwegians felt themselves compelled to take the matters into their own hands. Hagerup resigned, and in March 1905 Christian Michelsen (*q.v.*) formed a ministry of both parties, pledged to carry through the unilateral establishment of a Norwegian consular service. A bill to this effect was passed by the *storting* but on May 27, 1905, the king refused to sanction it. The Norwegian ministry immediately resigned; the king refused their resignation, but they declined to withdraw it. On June 7 the *storting* unanimously resolved that the personal union with Sweden was dissolved because the king was unable to have an alternative government formed. The resigning ministry was authorized to exercise the authority vested in the king.

The decision aroused bitter feelings in Sweden, but due to the influence of the king and of the Swedish Liberals and Socialists the *riksdag* (Swedish parliament) agreed to negotiate on the issue raised, on certain conditions. One of them was a general plebiscite in Norway; this was held on Aug. 13, resulting in 368,208 votes for severance of the union and 184 against it. On the other conditions an agreement was reached on Sept. 23. This provided for a neutral zone on both sides of the frontier, the Norwegians undertaking to dismantle some fortifications in the zone. On Oct. 26, after ratification by *storting* and *riksdag*, King Oscar II relinquished the crown of Norway. Failing acceptance by a Bernadotte, it was conferred upon Prince Charles of Denmark, grandson of King Christian IX, after a second plebiscite in which the voting was approximately four to one in favour of monarchy rather than a republic. On Nov. 25 the king, having adopted the name Haakon VII, and his wife Queen Maud, the youngest daughter of Edward VII of England, entered the Norwegian capital. (D. Ma.)

E. Modern Norway

Early 20th Century and World War I.—The truce to party politics created by unanimity on the question of terminating the

Swedish union did not long survive the retirement of Michelsen in Oct. 1907. The coalition government continued for five more months, under the leadership of its former foreign minister Jørgen Løvland, but for the next 12 years the Liberal or Left (Venstre) party generally maintained its predominance, though the elections of 1909 brought it a temporary setback in consequence of a split on the question of the Concession laws, which constituted the main political issue in the earlier years of that period. These laws were designed to control the power of foreign capital and, in the minds of the more radical politicians, of capital generally. They made the industrial exploitation of the natural resources of the country subject to a government concession, with eventual reversion to the state of the property involved, together with the plant and buildings erected upon it, without compensation. In consequence of the secessions from his party, Gunnar Knudsen's Liberal government, which was in power from 1908 to 1910, was succeeded by a coalition of Conservatives and moderate Liberals, first under Wollert Konow and then under Jens Bratlie, till 1913, after which Knudsen ruled without a break until 1920.

The industrial developments with which the Concession laws were concerned were, however, symptomatic of a fundamental change in the economic life of the country, which fortuitously coincided with the restoration of Norwegian independence in 1905 and had far-reaching political and social consequences, including a disturbance of the existing balance of political forces. It was in 1905 that Samuel Eyde founded Norsk Hydro, the great Norwegian nitrate organization, based on the use of hydroelectric power. The harnessing of Norway's enormous resources of water power started an industrial revolution with a suddenness which created problems and conflicts of capital and labour not previously experienced. Industrial disputes promoted the growth of organized labour and of a political Labour party the strength of which had hitherto been negligible. In these circumstances the dominance of the old Liberal party could not long continue.

On the outbreak of World War I the three Scandinavian countries at once proclaimed a policy of neutrality primarily designed to preclude any possibility of hostile action between them. They co-operated closely, and numerous conferences were held between their representatives. Norwegian shipping, however, rendered most valuable services to Great Britain, and from 1917 such services were the subject of a comprehensive agreement with the Norwegian Shipping association. Losses of life and tonnage were heavy, but the profits earned were extremely large. The wave of speculation which ensued brought temporary prosperity to a new and undesirable class of capitalists and thus further embittered the relations between capital and labour.

1919–39.—The Labour party, at this stage, was of an extreme revolutionary type, and in 1919 it joined the Third (Communist) International. Its growth in numbers, which in 1921 gained it 29 seats in the *storting*, reduced the Liberal forces to approximate equality with the Conservatives, though these old parties were still each considerably stronger than the Socialists: this situation and the adoption of a system of proportional representation (abandoned in 1949) led to a succession of short-lived governments, alternating between Conservative and Liberal, between 1920 and 1928.

In 1923 the Labour party withdrew from the Third International, and a Communist party was formed by its recalcitrant left wing. This split, however, did not entail any substantial loss, and in 1927 Labour became the strongest single party in the *storting*, with 59 seats. Its policy was still extreme enough to excite fear and suspicion in bourgeois circles, and when in Jan. 1928 it first assumed power as a minority government under Christopher Hornsrud it only survived for 18 days, being replaced by a Liberal administration under Johan Ludwig Mowinckel (*q.v.*), who remained prime minister till 1935, except for a break in 1931–32, when an Agrarian government under Peder Kolstad was in office. Kolstad died in March 1932, and the leadership passed to Jens Hundseid until the fall of the government in Feb. 1933. The elections of Oct. 1933, however, gave Labour 69 seats, and from 1935 they remained securely in power, under Johan Nygaardsvold, though without an overall majority until 1945.

After the settlement of the Concessions question, the principal domestic issue in the decade following World War I turned on the prohibition of intoxicating liquors, which had been introduced as a temporary expedient during the war and the continuance of which was supported by a referendum in Oct. 1919. The experiment proved unsatisfactory, leading to widespread smuggling and other evasions of the law, beside producing a trade conflict with Spain and Portugal which caused heavy loss to the fishing industry. The measure was repealed, except in relation to spirits, in 1923; the prohibition of spirits was likewise abandoned in 1927.

In external affairs the most important events were the recognition of Norwegian sovereignty over Svalbard (Spitsbergen) from 1925, and a dispute with Denmark over Norwegian rights in east Greenland, which was decided in favour of Denmark in 1933, by the Permanent Court of International Justice. For the last ten years preceding World War II Norway was seriously affected by the world economic crisis, and widespread unemployment promoted the progress of socialism.

World War II.—In the years following World War I, Norway had been a loyal and active member of the League of Nations, in the work of which Fridtjof Nansen (*q.v.*) played a conspicuous part. But the experience of the Italo-Abyssinian conflict shook the country's faith in the security offered by the league, and on July 1, 1936, Norway, together with its associates in the "Oslo group" (Belgium, Netherlands, Luxembourg, and the other Scandinavian states), repudiated the obligation to assist in the enforcement of sanctions under the covenant. The Norwegian government announced in April 1938 its intention to abstain from participation in the event of war.

On the eve of the outbreak of World War II in 1939 the Scandinavian countries together proclaimed their reversion to a policy of strict neutrality. This policy seemed at first sight to be more disadvantageous to the western allies than to Germany, which was able to use a long stretch of sheltered territorial waters for the conveyance of Swedish iron from the Norwegian port of Narvik. During the Russo-Finnish campaign of 1939–40, in which Norwegian sympathies were strongly pro-Finnish, France and Great Britain tried to induce Norway to abandon its neutrality sufficiently to allow the transit of Allied troops through Norway to Finland, but the request was refused. In Feb. 1940 British naval forces entered Norwegian territorial waters to rescue a number of Allied prisoners from the German vessel "Altmark," which had taken refuge in Jøssingfjord. On April 8 the Allies went further and announced the mining of various points in Norwegian territorial waters, with the object of preventing their use for the safe conveyance of German supplies. It was not, however, from the west that Norwegian neutrality was seriously threatened: on April 9, 1940, the country was suddenly invaded by Germany.

This event found the Norwegian people completely unprepared. During the interwar period, the defenses of the country had been neglected by all political parties for a variety of reasons. Faith in the protection afforded by the League of Nations and the prevalent view that the reduction of armaments was a virtue played an important part in the earlier stages. With the rise to power of the Labour party, motives of economy or of diverting expenditure from military to social objects combined with the ingrained pacifism of the older Socialists (who were also afraid that the army might be used in internal conflicts to the detriment of the working class) to produce a similar result. Halvdan Koht, the foreign minister, while he tried to the last to maintain a strictly neutral policy, was also obsessed with the idea that this neutrality was threatened from the west rather than from Germany. He accordingly ignored a number of warnings that reached him during the final days preceding the invasion.

The project of a German occupation of Norway, however, was under consideration in Germany as early as Oct. 1939, where it was strongly pressed by the admiralty. By the middle of Jan. 1940 the plan was adopted by Adolf Hitler, who had been more or less converted after an interview with the Norwegian traitor Vidkun Quisling (*q.v.*) in the previous month.

The destruction of the German cruiser "Blücher" by the Oscarsborg batteries in the narrows of the Oslofjord threw out the

German timetable sufficiently to enable the king and his government to escape from the capital to Elverum, where an extraordinary meeting of the *storting* voted full powers to the government to act during the emergency. The German demands, which included the appointment of Quisling as premier, were rejected by the king and his ministers, and active resistance by the improvised forces available began at once. This was continued for about two months, but by the beginning of June dangers on other fronts compelled the withdrawal of the assistance meanwhile provided by the Allies, including their abandonment of the port of Narvik (*q.v.*). The king and government moved to England, and active hostilities in the country came to an end. From London, nevertheless, the king and his ministers retained continuous radio contact with the loyal elements in Norway, while from the first they had succeeded in diverting practically the whole Norwegian merchant fleet to the service of the Allies. (*See* also WORLD WAR II: *German Campaigns in Denmark and Norway*.)

The Germans were slow to grasp the extent of the antagonism that they had aroused in the Norwegian population and made a particularly serious mistake in supporting Quisling and his party, who were despised by all but a fraction of the people. In the temporary depression induced by the fall of France, indeed, there was a dangerous moment when the presidential board of the *storting* was prevailed upon to request the abdication of the king and the resignation of the government. But when this demand was met with a dignified refusal a bolder spirit quickly developed, and in September Germany abandoned the hope of giving the occupation any appearance of voluntary acceptance by the Norwegians. A German *Reichskommissar*, Josef Terboven, was appointed, under whom various members of Quisling's party were given administrative charge of the different departments of state. On Feb. 1, 1942, Quisling himself was raised to the position of "minister president" over a puppet government of his supporters, but this move effected no real change in the situation.

A Home Front growing spontaneously from the uncoordinated efforts of individuals became increasingly organized under a central leadership whose members were soon in continuous touch with the Norwegian government in England. The directives issued to the people through secret channels by this organization found a ready and loyal response which seriously obstructed the plans of the occupying power and its puppets, while a large number of "illegal" newssheets kept the population informed. Resort to guerrilla warfare or to unauthorized acts of sabotage was wisely discouraged, though a secret military organization existed and was approved. The Home Front was drawn from all political parties and classes of the nation, and it thus fostered a new spirit of unity that ignored political differences.

Postwar Years.—Norway was liberated in May 1945. The wartime government headed by Johan Nygaardsvold immediately resigned and was succeeded temporarily in June by a coalition under the prime ministership of the Labour party leader, Einar Henry Gerhardsen (*q.v.*). A general election on Oct. 8 returned the Labour party again to power, with 76 seats out of 150. The Communists won 11 seats at the close of the war, but they lost them all in the election of Oct. 10, 1949, in which the Labour party increased its representation to 85. Gerhardsen continued as prime minister until Nov. 1951, when he was relieved for a time by his colleague Oscar Torp, resuming the premiership in Jan. 1955.

Domestic policy in those years mainly centred on problems of finance and reconstruction inherent in the postwar situation. These were for the most part approached on lines laid down in a program agreed upon by all parties at the close of hostilities. In its external affairs, however, Norway made a striking departure from its traditional attitude of neutrality. For the first few years, indeed, the aspiration of all the Scandinavian states was to build a bridge between the conflicting ideals of the western world and the U.S.S.R., while avoiding association with either side. As early as the close of 1947, however, Norway began to entertain serious misgivings, and the Communist coup in Czechoslovakia in Feb. 1948 convinced it of the impracticability of this "bridge-building" policy. The three Scandinavian states thereupon discussed the alternatives of association with the North Atlantic Treaty organization (NATO) and a neutral defensive alliance among themselves as preferred by Sweden); but early in 1949 agreement proved impossible, and Norway joined NATO. In Nov. 1959 Norway was a signatory to the convention setting up the European Free Trade association (EFTA), which came into effect in May 1960. Norway's application (1962) to join the European Economic community (EEC) was shelved following the breakdown (Jan. 1963) of negotiations concerning a similar application by Britain.

The elections of Oct. 12, 1953, followed an important amendment (1952) of the electoral law, which abolished the preponderance of rural over urban representation laid down in the constitution of 1814. At the elections of 1957 and 1961 Labour remained by far the largest party in the *storting*, although in 1961 it just lost its overall majority. But in 1963, after 28 years in office, the Labour party fell from power, and John Lyng, leader of the Conservatives, took office at the head of a coalition government on Aug. 28. On Sept. 18, however, Lyng's policy statement was rejected in the *storting*, and Labour returned to power under Gerhardsen.

In 1965 Labour was again defeated, 80 seats in the *storting* being won by the Conservative, Centre, Christian People's and Liberal parties, against Labour's 68. Per Borten, leader of the Centre party, became prime minister. Increased taxation in 1966 somewhat neutralized a major wage settlement negotiated by compulsory arbitration. Neither event hindered economic expansion, though credit restrictions were tightened in the autumn. On Jan. 1, 1967, a new wage-based pension plan came into force.

In 1955 Norway had celebrated the conclusion of 50 years of national independence and the jubilee of its king, to whose firm though strictly constitutional leadership the whole nation recognized its indebtedness. On Sept. 21, 1957, King Haakon died at the age of 85. His 54-year-old son was immediately sworn in as the new monarch, King Olav V (*see* OLAF). (G. M. G.-H.; X.)

IV. POPULATION

The population of Norway at the census of Nov. 1, 1960, was 3,494,089 as compared with 3,278,546 at the 1950 census and 2,814,194 in 1930. At Jan. 1, 1964, it was estimated at 3,680,622. The table shows its distribution over the 20 *fylker* (counties).

Norway is the most thinly populated country in Europe, with an average population density of 29 per square mile. Towns are few, and apart from Oslo (whose boundaries were greatly extended in 1948) and Bergen (*qq.v.*) none has a population of more than 100,000. According to the census of 1960 Trondheim had 58,196, Stavanger 50,949, Drammen 30,530 and Kristiansand 27,941. Most of the built-up areas are found along the coast, in the lowlands of the east (Østlandet), in the area around Trondheim (Trøndelag) and in the larger valleys. The most sparsely populated area is the north, particularly the county of Finnmark, where most of Norway's 20,000 Lapps are found. By mid-20th century less than one-tenth of the Norwegian Lapps (*samer*) were reindeer keepers; most had deserted their nomadic existence and settled as farmers and fishermen along the coast.

The population of Norway in 1801 was less than 1,000,000 but from 1815 there was a fairly rapid increase, much of it, however absorbed by emigration, chiefly to the United States. Between 1836 and 1936 the total number of emigrants was 860,694. After 1931 emigration declined considerably, in view of immigration restrictions in the United States and increased economic opportunities at home. Between 1946 and 1962 the number of emigrants was 34,809, with a peak in 1952 of 2,958.

The number of live births rose steadily from 41,321 (the lowest figure recorded in the 20th century) in 1935 to 70,727 in 1946. In 1963 it was 64,105. The excess of births over deaths was 27,546 in that year. The live-birth rate in 1963 was 17.5 per 1,000 inhabitants, the death rate 10.0. The marriage rate, at 9.5 per 1,000 inhabitants, reached its peak in 1946. In 1960 there were 1,789,403 men and 1,801,831 women—an excess of women over men of 12,428 as compared with 70,356 in 1930. The percentage of illegitimate live births fell from 7.1 in 1930 to 3.7 in 1960.

The age distribution of the population after World War II was strongly influenced by the great variation in the birth rate, the all from 1920 to 1935 and then the subsequent rise. While the popu-

lation as a whole has increased steadily, the proportion of old people has increased most.

V. ADMINISTRATION AND SOCIAL CONDITIONS

1. Constitution and Government.—Norway is a constitutional and hereditary monarchy. The constitution or fundamental law (*grunnlov*) was adopted by the constituent assembly at Eidsvoll on May 17, 1814, and amended at various times since. Executive power is vested in the king, exercised through a council of state consisting of the prime minister (*statsminister*) and at least seven other councilors (*statsråder*). The councilors are the heads of the ministries (*departementer*); they also sit in the parliament (*storting*) but do not vote. The king has no power to dissolve parliament, its life being fixed at four years. The 150 members (*stortingsmenn*) of parliament are elected directly by the people in electoral districts which correspond to the 20 counties.

The right to vote is enjoyed by all Norwegian citizens, men and women, over 21 years of age who have resided five years in the country. Candidates must have resided ten years in the country and must be over 21 years of age. Since 1953 candidates need not be resident in the constituency in which they stand for election. Substitutes as well as members are elected. Since 1961 the *storting* is elected in September every fourth year, and meets in Oslo on the first weekday in October each year, remaining assembled as long as is necessary. After the opening, parliament divides itself into two sections, the *lagting* consisting of 38 members and the *odelsting* of the remainder. A bill is first introduced in the *odelsting* and, if passed, is sent to the *lagting*. If the two sections do not agree, the bill is returned to the *odelsting* for further deliberation, and the *odelsting* may return it to the *lagting* with or without amendments. If the *lagting* still does not agree a joint session is held and a decision made by a two-thirds majority of the combined votes. A bill can become law without royal assent if passed by two ordinary sessions of parliament after two separate and successive elections (these sessions having to be separated by at least two other ordinary sessions of parliament) provided no divergent legislation has been passed between the first and last passage of the bill. Budget proposals and other questions not taking the form of bills are dealt with by parliament as a single body. There are a number of standing committees where most questions are discussed before reaching the full assembly.

Local Administration.—The country is divided into 20 *fylker* (see Table) including the cities of Oslo and Bergen. In 1964 there were 49 urban (*by-kommuner*) and 476 rural districts (*herredskommuner*), rearrangement having reduced their numbers from respectively 58 and 647 since 1962. The local districts are run by councils (*kommunestyre*) elected every fourth year. Each council elects a presidency of one-quarter of its members. In each county except Oslo and Bergen there is a county council (*fylkesting*) consisting of members of the commune councils. Each commune council elects one representative to the county council per 6,000 inhabitants of the commune. The county council is presided over by a chairman elected by the council from among its members. A county governor (*fylkesmann*) appointed by the

king supervises administration. The scope of municipal affairs in Norway is very wide. Revenue derives from local income tax, municipal trading profits and state grants.

2. Political Parties.—Of these the principal ones are: the Arbeiderparti or Labour party (with 74 seats in the *storting* of 1961–65), whose object is the development through parliamentary means of economic and social democracy where all able men and women associate in the responsibility for and control of their own livelihood; the Høyre or Conservative party (29), which regards the productive powers of individuals in free competition as the basis for the economic and social well-being of the whole community; the Venstre or Liberal party (14), which considers that the principles of respect for the individual and of national solidarity should be protected under government supervision; the Senterparti or Central party (16), formerly the Bondeparti (Farmers' or Agrarian party), which stands for a society where everybody is equally rewarded according to his contribution to the national product; the Kristelig Folkeparti (Christian People's party) (15), which holds Christianity as the foundation of democracy, defined as freedom, brotherhood and justice in accordance with the law of God; the Sosialistisk Folkeparti (Socialist People's party) (2) which urges disarmament, the country's withdrawal from NATO and a speedy course toward socialism; and the Communist party (0), with its dogmatic marxist program.

3. Taxation.—Direct taxes are levied by local authorities as well as by the central government on personal income and property. Taxes are progressive in relation to income and property, but are assessed according to the taxpayer's family responsibilities. Total taxes on an average income amount to about 25% of the income for a single person and 10% for a family of five. Tax on property varies from about 0.4% up to 1–2%. Maximum taxation payable is 80% of the income received.

4. Living Conditions.—*Wages.*—Wages are in general fixed by rates agreed upon by employers' and employees' confederations for a 2–4 years' period. Contracts may be amended within the period if the cost of living index numbers fluctuate beyond limits laid down. In the early 1960s male workers' average earnings in manufacturing and construction industries corresponded to a yearly income of kr. 10,000–15,000 ($1,400–2,100); farm workers' wages to about kr. 10,000 yearly. Depending on qualifications and responsibilities yearly salaries for office employees averaged about kr. 12,000–33,000 ($1,700–4,600), for technical employees kr. 13,000–47,000 ($1,800–6,600). About 75% of the economically active population are wage earners. Seasonal unemployment in construction and some other industries averaged about 30,000 in January and 4,000 in July.

Housing.—By 1960 the demand for housing had increased greatly because of the increase in population after World War II and the lack of building during the war. There was also a demand for improved living conditions resulting from a general rise in personal incomes. An average family spends 10–12% of its income on housing, light and fuel. Nearly all homes have electricity and main water supply, and in the towns and other densely settled areas no house is built without modern plumbing, and such amenities are being extended to rural areas.

Trade Unions.—In the 1960s about two-thirds of the total number of employed persons were members of trade unions or associations of employees. About 80% of these were members of unions organized by Arbeidernes Faglige Landsorganisasjon i Norge (Norwegian Federation of Trade Unions), the largest of which are the unions of Iron and Metal Workers, Municipal Employees, Building Industry Workers, Seamen, and Commercial and Office Workers. About 62% of all members of trade unions and employees' associations were employed by enterprises which are members of employers' associations, the most important of which is the Norsk Arbeidsgiverforening (Norwegian Employers' Confederation).

Social Security.—There are national insurance plans to meet most contingencies. Compulsory health insurance was enacted in 1909 and old-age pensions were introduced in 1936 for all citizens 70 or more years of age. There are accident-insurance plans (which originated in the 1900s) for industrial workers, seamen and

fishermen. Compulsory unemployment insurance was introduced in 1938; family allowances in 1946; and three-week vacations with pay for all workers in 1947 (extended to four weeks from 1965).

Health Services.—Norway had in the early 1960s more than 4,000 licensed medical practitioners and 2,500 dentists. In each of more than 400 public health districts a medical officer controls the enforcement of health laws, makes provisions against epidemic diseases and advises the local authorities on public sanitation. In some isolated areas he is the only available doctor. Medical care is introduced in elementary and secondary schools, and dental care for the majority of school children. Mass X-ray of the lungs is compulsory for all inhabitants. Norway has more than 200 general hospitals, in addition to hospitals for tuberculosis, mental hospitals and nursing homes for the mentally diseased and feebleminded. Hospitals are mainly controlled by public authorities, some being the care of humanitarian or religious organizations.

5. Justice.—A special feature of Norwegian legal procedure is that civil cases are usually brought first before a mediation council (*forliksråd*), from which an appeal lies to the commune courts (*by- og herredsrettene*), which are also tribunals of first instance. The town and county courts have a professional judge, sometimes assisted by two lay judges. There are five courts of appeal (*lagmannsretter*) in Oslo, Bergen, Trondheim, Skien and Tromsø, composed of three professional judges; and a supreme court (*høyesterett*) in Oslo, whose decision is final. The *lagting* (section of the *storting*) and the *høyesterett* together form the high court of the realm (*riksrett*) for the trial of ministers and members of the *storting* and the *høyesterett* itself. Criminal cases are tried either in the *lagmannsrett* with three judges and ten jurors, or in summary court (*forhørsrett*) with one professional judge, or in town and county courts with a professional judge, usually assisted by two lay judges. The *lagmannsrett* is for more serious offenses; the others for minor offenses. Capital punishment has been abolished (1905) except for certain military and treasonable crimes. There is a state police force subordinate to the ministry of justice.

6. Education.—This is financed jointly by the state, the municipalities and private funds. All instruction is free. Elementary education has been free and compulsory for all Norwegian children between 7 and 14 years of age since 1860. In the early 1960s there were more than 4,000 primary schools with about 430,000 pupils. There were also one-year primary continuation schools. Since 1959 the extension of school-leaving age to 16 has been authorized by law and this extension had been applied in some primary schools by the early 1960s. There are about 300 secondary schools (state, communal and private) most of which can grant certificates. There are also technical, industrial, art and other schools, and teacher-training colleges. Norway's two universities are at Oslo (1811) and Bergen (1948). Other higher educational institutions are the state colleges or institutes of agriculture (Ås district), veterinary science (Oslo), technology (Trondheim), a school of economics and business administration at Bergen, and an independent theological college at Oslo.

7. Defense.—The king is supreme commander of the armed forces. Under the ministry of defense is a defense staff with combined control of all land, sea and air forces. There is a system of local command areas for the three services. A considerable reconstruction of the armed forces was started in 1945 and accelerated after 1949, when Norway joined NATO. Compulsory military service in peacetime was fixed at 12 months; it was increased to 16 months in 1954 for army recruits and 18 months for the navy and air force. In the early 1960s the standing army strength was estimated at 23,000 men; but about 200,000 men could be mobilized at short notice in all branches, including the national guard. The army could mobilize field units corresponding to about two divisions, with many of the men trained in West Germany (where Norway after World War II maintained an occupation brigade of about 4,000). The national guard was formed in 1946 and soon had a membership of about 100,000, mostly volunteers. The air force had about 200 jet fighters and other aircraft. The navy had as its main strength three destroyers, five frigates, eight submarines, as well as a number of corvettes, minesweepers and motor torpedo boats. Coastal artillery, with powerful batteries left by the Germans, was concentrated in particular areas, and antiaircraft artillery was strengthened.

VI. THE ECONOMY

1. State Control and Ownership.—After 1945 (when the Labour party first secured a parliamentary majority) the economy of Norway was fairly strictly controlled and directed along the lines set out in the annual national budgets. Those budgets laid down economic policy in such spheres as investment, consumption, imports, exports, manpower and materials. A system of licences, quotas, price controls and subsidies was used to ensure the desired development of the national economy. The government also influenced economic development by direct or indirect ownership or part-ownership of mines, factories and other concerns in such fields as aluminum, hydroelectricity, chemicals and transport. State monopolies over grain and alcohol had been established before World War II. In 1960 Norway signed the European Free Trade association (E.F.T.A.) treaty.

2. Agriculture and Forestry.—Agriculture has remained one of the principal resources of the country, though in the early 1960s it supported 15% of the population, compared with 30% in 1930. According to the agricultural census of 1959, 2.7% of the land area was cultivated and there were more than 138,000 farms and holdings of 2 ha. or more, mostly small and nearly all owned by the farmers. Natural conditions are favourable to fodder growing and livestock keeping, and Norway is self-sufficient for nearly all livestock products. Only half the domestic consumption of cereals is produced in Norway; nearly 70% of grain harvested is barley and most of the rest oats. More than 1,000,000 tons of potatoes and over 3,000,000 tons of hay and straw are produced annually.

Farmers derive an important part of their income from forest holdings. Forests cover about a quarter of the land area. About 80% of the forest area is privately owned, while the state and local authorities own the rest. There are about 125,000 forest holdings. For centuries sawn and planed timber had been Norway's main forest export, but most of the timber is now exported as pulp and paper. In the early 1960s about 275,000,000 cu.ft. of timber were cut yearly for sale and about 1,500,000 tons of pulp and more than 800,000 tons of paper and paperboard were produced.

3. Fisheries.—According to the fishery census of 1960 there were more than 60,000 fishermen, of whom 45,000 had fishing as their sole or main occupation. Fishing vessels exceeded 36,000, of which about 12,000 were decked motor vessels, mostly owned by the fishermen themselves. Fishing is carried on for the most part close to the shore. Catches exceed 1,300,000 tons a year and consist mainly of herring and cod. Much of the herring catch is processed into oil and meal. Pelagic whaling was pioneered by the Norwegians in the antarctic early in the 20th century. Norway sends several whaling expeditions to the antarctic annually and whale and sperm oil are produced.

4. Industry, Mining and Power.—An extraordinary expansion in the industrial life of Norway set in at the end of the 19th and the beginning of the 20th century as the result of the development of cheap and plentiful hydroelectric power. This expansion was further accelerated after 1945. It has been particularly notable in the electrochemical and electrometallurgical spheres. The manufacture of pure nitrogen in the early 1960s was more than 300,000 tons (equivalent to about 1,500,000 tons of fertilizer products), and more than 500,000 tons of ferroalloys and aluminum were produced, nearly all for export. The construction of electrical and other machinery and shipbuilding also made marked headway. The mining industry, extracting mainly iron ore and pyrites, is concentrated mostly in the northern part of the country. Copper and zinc are by-products. The steel output was about 500,000 tons. The output of sulfur declined to about 45,000 tons compared with more than 100,000 tons in the early 1950s. The production of ferrosilicon became important.

After 1945 a high rate of investment, particularly in hydroelectric development, industry and shipping, was instituted. Of Norway's estimated exploitable water power of about 15,000,000 kw., more than 4,000,000 kw. had been harnessed by the early 1960s

The output of electricity per capita was the highest of any country in the world. As the result of this expansion, the industrial production index had more than doubled since 1949. In farming, fishing and forestry, production also improved through mechanization despite the loss of labour to industry.

5. Foreign Trade.—Norway's foreign trade, which had always been large in relation to population, increased further after 1945, and by the early 1960s the value of imports ran at nearly kr. 16,000,000,000 and that of exports at about kr. 8,000,000,000. The trade deficit was largely financed by freight earnings of the merchant fleet. Principal imports were machinery and apparatus, ships ores and metals, fuels, chemicals and textiles. Exports included pulp and paper, fish, fish products and marine oils, fertilizers and other chemicals, and ores and metals. Relatively few types of commodity are exported; the products of the pulp and paper industry, the electrochemical and electrometallurgical industries and the fisheries together account for about 60% of exports. The chief trading partners were the United Kingdom, West Germany, Sweden and Denmark.

The Norwegian merchant fleet amounted in the early 1960s to more than 13,000,000 gross tons (ships over 100 gross tons), about half the tonnage consisting of tankers. This fleet, the fourth largest in the world, lost half its tonnage during World War II but was rapidly rebuilt after 1945, with replacements mostly from British and Swedish yards. The majority of the vessels are engaged in overseas traffic between foreign ports.

6. Currency and Finance.—The unit of currency is the krone, divided into 100 øre. The value of the krone is fixed at 20 to the pound sterling and (since devaluation of sterling in 1949) at 7.14 to the U.S. dollar. In the early 1960s the gold and foreign exchange holdings of Norges bank (the Bank of Norway) totaled about $300,000,000.

Norges bank, founded in 1816 and state-owned since 1949, is the sole note-issuing institution. During World War II the note circulation increased sixfold to about kr. 3,000,000,000, largely because of heavy drawings (about kr. 11,000,000,000) made on Norges bank by Germany. More than half this sum was repaid by Germany after the war, but, as a result of postwar reconstruction and economic expansion, the note circulation exceeded kr. 4,000,000,000 in the early 1960s.

The state budget had so increased as to become a decisive factor in the national economy, expenditure and revenue averaging kr. 11,000,000,000 and kr. 10,000,000,000 respectively. Taxes on income and capital raised about one-fifth of the revenue, the rest deriving mostly from purchase tax and other indirect taxes. The national debt stood at about kr. 14,000,000,000 of which one-sixth was owned abroad.

7. Communications.—Norway, with its long, narrow stretch of land, its fjords, mountains and islands and its sparse population, presents transport problems of especial difficulty. Coastal shipping and ferry connections play an important role, hydrofoil craft being used on some routes. The public road system totaled more than 33,000 mi. in the early 1960s. There were then about 500,000 motor vehicles, of which more than 300,000 were private cars. The first railway, from Oslo to Eidsvoll, was opened in 1854. The railway system covers more than 2,750 mi., of which more than 40% is electrified. International air traffic to western Europe is based on the airports of Oslo, Stavanger, Kristiansand and Bergen. Connection with transworld services is made via Copenhagen, Den. All-year daily internal services operate from these airports and also from Ålesund, Trondheim, Bodø and Tromsø. Seaplane services operate from April to October in northern Norway.

Telecommunications have a special importance in Norway because of its physical character. Telegraph and telephone services are mostly nationalized. In the early 1960s there were about 100 telegraph stations and 2,000 long-distance telephone stations, with about one telephone per five inhabitants. There are international telephone services and radio-telegraph and telex services. Broadcasting and television are the monopoly of the Norwegian National Broadcasting service (Norsk Rikskringkasting). Its headquarters are in Oslo, and there are 40 substations transmitting the national program; some substations transmit a local program for a short time daily. It was expected that in 1965, 80% of the population would be covered by television. *See* also references under "Norway" in the Index. (L. H. Hg.)

NORWEGIAN LANGUAGE is one of the Scandinavian languages (*q.v.*). Written Norwegian exists in two distinct and rival norms, known since 1917 respectively as *bokmål*, "book language," and *nynorsk*, "New Norwegian," but also referred to by their older names of *riksmål*, "national language" and *landsmål*, "country-wide language." The former, which may be called Dano-Norwegian since it stems from the written Danish introduced during the union of Denmark and Norway (1380–1814), has been modified in the direction of Norwegian speech by three spelling reforms (1907, 1917, 1938); the latter, which may be called New Norse since it was intended by its creator Ivar Aasen (1813–96) to carry on the tradition of Old Norse, was interrupted in the 15th century. Dano-Norwegian and New Norse are legally equal and are taught in all schools in forms regulated by the ministry of church and education under mandate from parliament. A permanent advisory language commission (*Språknemnda*) was appointed in 1952, with an equal number of representatives for each language nominated by various interested institutions. Governmental planning and natural diffusion have gradually reduced the differences between the two norms; and their eventual amalgamation in *samnorsk*, "common Norwegian," was envisaged—a plan which met with vigorous opposition.

Spoken Norwegian is divided into urban and rural dialects; the former has spread at the expense of the latter. Urban speech falls into standard and substandard social dialects. Standard urban

speech is reasonably uniform throughout the country and serves as a model, although some educated people prefer to speak a normalized New Norse or retain their rural dialects. The standard urban dialect is a compromise between traditional Norwegian speech habits and written Dano-Norwegian, as developed by the old official and professional class. Substandard urban dialects are closer to the surrounding rural dialects of each city, being historically the speech of rural-urban migrants. The rural dialects differ from parish to parish, but fall into broad regional types which reflect the paths of communication in medieval and early modern times: western (the fjord country from Romsdal to Setesdal), eastern (from Telemark to the Swedish border and north to the Dovre mountains), Tröndər (in the trading area of Trondheim), and northern (the three northernmost counties). New Norse has its strongholds in the western dialects, on which Aasen drew most heavily for his grammatical and lexical framework.

In general, Norwegian is a language with a complex, musical phonology, a greatly simplified grammar and an internationalized vocabulary. While the vocabulary is basically native, it contains a great number of originally Low German words for features of urban culture; in addition it has adopted the usual international words for modern technology and borrows new terms freely, most recently from English. New Norse is somewhat more puristic than Dano-Norwegian and attempts to eliminate especially the German and Danish elements from its vocabulary.

Great variety and flexibility are tolerated and even encouraged in the written language in Norway. Writers often resort to local urban or rural dialects. The most widespread and firmly entrenched is Dano-Norwegian, in which are written all daily newspapers, most translations from foreign languages, and from 80% to 90% of original writing. In the schools about 75% of the children learn it as their primary medium of writing.

NORWEGIAN LITERATURE. Among the literatures of modern Europe, Norwegian literature is remarkable for being so comparatively late-flowering and yet at the same time so impressively deep-rooted. Not until after the separation of Norway from Denmark in 1814, which brought with it a large measure of political independence, is it possible to point to a corpus of literature that is unambiguously Norwegian; yet so vigorous and so luxuriant was its development that by the end of the 19th century Norwegian literature—particularly by virtue of the massive achievement in drama of Henrik Ibsen (*q.v.*)—occupied an influential position.

Early Literature.—The roots of Norwegian literature reach back over 1,000 years, beyond the early Christian era and into a pagan past; there it becomes inextricably intertwined with early Icelandic literature. Although a large part of this early literature was composed either in Iceland or elsewhere in Scandinavia by Icelanders, the Norwegian element in it is considerable and indisputable, even though this cannot always be isolated and defined; in many instances, it is obvious that some of the literature derives from a time before the Scandinavian settlement of Iceland in the 9th century; and in other cases it must have happened that the composers of the works had resided for long periods in the mother country of Norway. At all events, Norwegian literature as it eventually took shape in modern times would have been unthinkable but for the impetus and the specific direction given to it by this ancient literary tradition—above all, by the mythological and heroic lays of the *Poetic Edda* (*see* Edda), by the scaldic poetry and by the myths of the sagas (*see* Icelandic Literature; Germanic Mythology and Heroic Legends).

Three Latin works from the late 12th century have perhaps more philological than strictly literary interest. *Historia de antiquitate regum Norvagiensium* (*c.* 1180), a history of the Norwegian kings from Harald I Haarfager to Sigurd I Jorsalafar, was written by Theodricus, a Benedictine monk from near Nidaros; *Profec Danorum in Terram Sanctam* (*c.* 1200) describes a crusade fro the years 1191–92 in which Norwegians and Danes took part; a *Historia Norvegiae* (discovered by P. A. Munch in 1849 in Sc land) offers an interesting but historically unreliable account Norway, in not very good Latin, giving brief details of No way's geography and fauna and including some interesting marks about the Lapps. The seminal influence of Snorri Sturl son's *Heimskringla*, a history of the kings of Norway to 11 written in Iceland in the first half of the 13th century, is al clear. Of great interest to the historian is *Konungs skugg* ("The King's Mirror"), written in Norway *c.* 1250; this is didactic work in verse which discusses the manners, customs an practices of the day. In the 13th century, the ballad also flou ished as an oral tradition, of which the *Draumkvæde* ("Drea Ballad"), a great visionary poem, is the most impressive survivi example. It describes the dream of Olav Aasteson, who sle from Christmas Eve to Twelfth Day, and, awaking in time to ri to church, recounted there the substance of his dream of purgator hell and heaven.

Translation was much encouraged by King Haakon V Magnu son during his reign (1299–1319); and a translation, with com mentary, of the Bible was begun, but progressed only as far a Exodus 18.

Danish Domination: 14th to 18th Centuries.—From th 14th century onward, the destiny and culture of Norway becam increasingly closely linked with and subservient to those of Den mark. Political union between the two countries came in 138 more and more the Danish language began to impose itself throug out the territory, especially in the towns, until it eventually becam both the official and the literary medium; and Copenhagen wi its university, established itself as the cultural capital of the "twi kingdom." Not until after the Reformation are there faint sig of renewed literary activity in Norway itself, after centuries virtual silence: Absalon Pederssøn Beyer (1528–75) and Pede Claussøn Friis (1545–1614), two clergymen, left their marks th former by his description of and rather nostalgic apologia fo Norway, *Om Norgis Rige* (written 1567; published 1781), and th latter by his translation of Snorri Sturluson. The most origina and most conspicuously Norwegian writer of this age was, how ever, Petter Dass (*q.v.*), whose *Nordlands Trompet* (*The Trum pet of Nordland*) gives a lively picture in verse of the life of a clergyman in northernmost Norway; although almost certain completed before the turn of the century, this work was no printed until 1739. His verses still live; the religious poems his contemporary, Dorothe Engelbretsdatter (1634–1716), on th other hand, possess only historical significance.

Distinguished above all others in this Dano-Norwegian tradi tion is Ludvig Holberg (*q.v.*), the "Molière of the North"; Nor wegian by birth, he lived for the greater part of his life in Copen hagen where he held a series of academic appointments at th university. From his first *succès de scandale*, the publication his mock-heroic poem *Peder Paars* in 1719, until his death he dominated Scandinavian literature; by his comedies of the 1720s— the best known of which are *Jeppe paa Bjerget* (*Jeppe of the Hi* and *Erasmus Montanus*—by his volumes of essays *Moral Tanker* (1744) and *Epistler* (1748–54), by his novel *Niels Kli* (1741, originally written in Latin) and by his scholarly and his torical publications, he has rightly come to be regarded both a the founder of modern Scandinavian literature and as the crea of the modern Dano-Norwegian literary language (*see* also Dan ish Literature).

In the second half of the 18th century, there was little nativ literary talent in evidence within Norway, apart perhaps from Christian Tullin (1728–65), a Christiania businessman, whose nature poems have some merit. But there were other signs tha Norway was beginning to assert its cultural aspirations: a Roya Norwegian Society of Learning was established in 1760 in Trond heim; and the so-called Norwegian society (Det norske Selskab rather less official but no less vigorous for that, was formed in 1772 by some young Norwegians resident in Copenhagen after one of their number, Johan Nordahl Brun (1745–1816), had wo

a literary competition with his tragedy *Zarine* (1772). This society, which lasted until 1812, set out to resist what its members felt to be the excessive German influence on Scandinavian literature; in addition to acting as the focus for a number of minor literary talents—Claus Fasting (1746–91), Claus Frimann (1746–1829) and Jens Zetlitz (1761–1821), for example—it provided the stimulus for the one deathless work associated with it: the uproarious tragicomedy *Kierlighed uden Strømper* ("Love Without Stockings"), written in 1772 by the gifted but wayward Johan Herman Wessel (*q.v.*). But when seen in historical perspective, the society's achievements were probably rather more nationalistic than strictly literary.

The Age of Wergeland.—After 1814 a new, exciting and difficult age began for Norway: difficult, because the problems—political, economic, social—were formidable; exciting, because an opportunity seemed to be offered for developing an independent and genuinely Norwegian culture and way of life. But there were deep differences of opinion as to how this could best be achieved. There were those, of whom J. S. C. Welhaven (*q.v.*) was the chief representative, who insisted that the existing Danish element in the country's culture should not, and indeed could not, be neglected; on the other hand there were those, for whom Henrik Wergeland (*q.v.*) was the acknowledged leader and spokesman, whose nationalistic pride led them to demand that the break with Denmark be as abrupt and complete as possible. In literature, as well as life, Welhaven stood for a coolly intellectual approach, for restraint and control, for a conscious sense of artistry, of which his own sonnet-cycle *Norges Dæmring* ("Dawn of Norway," 1834) is a characteristic product. Wergeland's was a more passionate and revolutionary spirit, impatient for action, politically engaged, aggressive and spontaneous, of which his enormous epic poem *Skabelsen, Mennesket og Messias* ("Creation, Humanity and Messiah," 1830) is a youthful but not untypical example, although it is generally held that his best poetry is to be found in the maturer works, like *Jan van Huysums Blomsterstykke* ("Jan van Huysum's Flower-Piece," 1840), for example, and *Den engelske Lods* ("The English Pilot," 1844). It was Wergeland who, by the sheer force of his personality, dominated the age: as a poet, as an orator, as a social reformer, even; and the clash between him and Welhaven, between the two factions associated with them—the "Patriots" and the "Intelligentsia," as they were called, respectively—and between the two viewpoints they represented, marked the beginning of an ideological conflict that persisted throughout the century and that still persists, in various modified forms.

National Romanticism.—The literature of the mid-19th century, often referred to as Norway's "national romanticism," continued to reflect the country's larger aspirations. A lively interest in its own native past underlay the compilation and publication, between 1841 and 1844, of the *Norske Folkeeventyr* ("Norwegian Folk Tales") by Peter Christen Asbjørnsen and Jørgen Engebretsen Moe (*see* ASBJØRNSEN, P. C. AND MOE, J. E.); in 1853 M. B. Landstad (1802–80) performed a similar service for the country's folk songs by bringing out his *Norske Folkeviser* ("Norwegian Folk Ballads"); P. A. Munch (1810–63) by his eight-volume history of the Norwegian people (1851–63) encouraged popular pride in the nation's great historical traditions; while Ivar Aasen (1813–96) was the creative spirit behind the *landsmål* movement, the establishment of a literary language based on rural dialects that were fairly intimately linked with the Old Norse language (*see* NORWEGIAN LANGUAGE). Many of the literary publications of these years—and not least the earlier works of Ibsen and Bjørnson in the 1850s and 1860s—turned consciously, both for inspiration and for their thematic material, to Norway's heroic past, and to what seemed to be its most direct modern descendants and natural heirs—the peasants. To these years belongs also the lyric poetry of Aasmund Olafsson Vinje (1818–70), the most striking characteristic of which is what the author himself called its "twin-sighted" ambivalence (*tvisyn*).

Realism.—In 1855 Camilla Collett (*q.v.*), Wergeland's sister, published *Amtmandens døttre* ("The Governor's Daughters"); this novel, by virtue of its discussion of the place of women in society and in marriage, might well be taken as marking the beginning of that trend in Norwegian literature which, with encouragement and stimulus from the immensely influential Danish critic Georg Brandes (*q.v.*), culminated in the 1870s and the 1880s in the realistic "problem" literature of Ibsen and Bjørnson and their contemporaries. *Samfundets støtter* (*Pillars of Society*), in 1877, was the first of a succession of problem dramas by Ibsen which soon created for their author a worldwide reputation—although it should not be overlooked that by this date he already had more than a quarter of a century of dramatic authorship behind him, including his two important verse dramas, *Brand* (1866) and *Peer Gynt* (1867), and his long and ponderous "double-drama" in ten acts, *Kejser og Galilæer* (*Emperor and Galilean*, 1873). *En fallit* (*A Bankruptcy*), the first substantial drama of this type by Bjørnstjerne Bjørnson (*q.v.*), appeared in 1875, following his highly successful debut in 1857 with *Synnøve Solbakken*, the first of a series of "peasant tales." Although never the world figure that Ibsen became, Bjørnson was the leading personality of his age within Norway, not only in literature as a novelist, dramatist and lyric poet but also in many aspects of public affairs.

Traditionally associated with Ibsen and Bjørnson to form the "Big Four" of Norway's literature are the novelists Jonas Lie (*q.v.*) and Alexander Kielland; among them they made of the years 1879 to 1884 something of a minor miracle of productivity: Ibsen's *Et Dukkehjem* (*A Doll's House*), *Gengangere* (*Ghosts*), *En Folkefiende* (*An Enemy of the People*) and *Vildanden* (*The Wild Duck*); Bjørnson's dramas *Leonarda*, *Det ny system* (*The New System*), *En Handske* (*A Gauntlet*), *Over Ævne I* (*Beyond Our Power*) and his novel *Det flager i byen og på havnen* (*The Heritage of the Kurts*); Lie's novels *Rutland*, *Gaa Paa* ("Go Ahead"), *Livsslaven* (*One of Life's Slaves*) and *Familjen paa Gilje* (*The Family at Lilje*); and Kielland's *Garman & Worse*, *Arbeidsfolk* ("Workers"), *Skipper Worse*, *Gift* ("Poison") and *Fortuna*. Lie's first novel, *Den Fremsynte* (*The Visionary*, 1870), did not appear until its author was 37; his sense of telling detail, so typical of his art, is however seen more clearly in some of the later works, *Tremasteren 'Fremtiden'* (*The Barque "Future,"* 1872) and *Lodsen og hans Hustru* (*The Pilot and His Wife*, 1874), for example, and later still in *Kommandorens døttre* (*The Commodore's Daughters*, 1886); while the works of the final section of his career, such as *Onde Magter* ("Evil Powers," 1890) and *Trold* (1891–92), tell of the secret and uncontrollable forces that lurk deep in the personality. Kielland was the foremost stylist of his age, an elegant and witty novelist, though possessed of a strong social conscience and an active reforming zeal that owed much to his admiration for John Stuart Mill; after a prolific decade of authorship in the 1880s, during which he wrote eight novels, three plays and a number of shorter pieces, he virtually gave up writing and produced little during the rest of his life.

In the literature of the 1870s, with its emphasis on the individual's right to free development and free expression in defiance of the allegedly stultifying influence of organized authority—the state, the church, the press—and of outmoded convention, there was a belief in the possibility of social improvement that can only be called optimistic; in the following decade, a growing skepticism and even disillusionment made these literary attacks more bitter and more audacious, and they were directed against many of the social institutions widely regarded as essential to "respectability"—the family, marriage, religion. The publication of *Fra Kristiania-Bohêmen* ("From the Christiania Bohème") in 1885 by Hans Jaeger (1854–1910) created, by its seeming advocacy of sexual licence, a great public scandal. The most extreme exponent of Naturalism in these years was however probably Amalie Skram (1846–1905), especially in her four-volume novel *Hellemyrsfolket* ("The People of Hellemyr," 1887–98). Much more difficult to classify, but also a much greater writer, was Arne Garborg (*q.v.*), in whose works the successive movements of romanticism, realism, naturalism and neo-romanticism can be seen stratified. His wider reputation was first established with the novel *Bondestudentar* ("Peasant Students") in 1883, in which the details of student life in the Norwegian capital in the 1880s are movingly described; and he continued in the naturalist style in a

number of later novels. He was also a dramatist and critic; but many would claim that his greatest achievement was the poem-cycle *Haugtussa* (1895), some poems from which were set to music by Edvard Grieg.

The New Irrationalism.—A deliberate break with the older and more socially orientated literature came with the 1890s, when the established great ones of Norwegian literature came under fire from the new generation of writers. The real manifesto of the new ideas was the essay published in 1890 in the periodical *Samtiden* by Knut Hamsun (*q.v.*), "Fra det ubevidste Sjæleliv" ("From the Unconscious Life of the Mind"), which exhorted writers to give their attention rather to what was individual and idiosyncratic than to what was typical and everyday. Hamsun's own early novels splendidly exemplify these ideas: *Sult* (1890; *Hunger*), *Mysterier* (1892; *Mysteries*) and *Pan* (1894); his later novels, of which his *Markens Grøde* (1917; *Growth of the Soil*) is the best known, are in this respect less extreme, as well as being more moralist, more conservative, though still shot through with a strong and sometimes savage irony. Hamsun won the Nobel prize for literature in 1920. More than 20 of his novels—practically his entire output—have been translated into English.

Lyric poetry also flourished with new vigour in this decade, the most remarkable figure being Sigbjørn Obstfelder (1866–1900), whose lyrics and prose poems show a close affinity with the prevailing Symbolist movement in Europe; Nils Collett Vogt (1864–1937) also produced some of his best lyrics in the '90s. In drama, the new spirit found clearest expression in the works of Gunnar Heiberg (1857–1929), who combined a sharply satirical wit with a lyric deftness, whereby sometimes the one predominates as in *Kong Midas* (1890), and sometimes the other, as in *Gerts Have* ("Gert's Garden," 1894); both his *Balkonen* (*The Balcony*, 1894) and his *Kjærlighetens Tragedie* (*Tragedy of Love*, 1904) are impressive in their erotic force.

Of the same generation as Hamsun, and in large measure sharing his preoccupation with the irrational side of human conduct, was Hans Kinck (1865–1926), a writer of tremendous power and penetration; Kinck however was a much more reflective and intellectual writer than Hamsun, and his work was more analytical, especially his verse-drama *Driftekaren* (*The Drover*, 1908) and his three-volume novel *Sneskavlen brast* (*The Avalanche Broke*, 1918–19).

The 20th Century.—Surprisingly for a country in which, in the persons of Ibsen and Bjørnson, the tradition of drama had been so strong, the real achievements in Norwegian literature in the first half of the 20th century were made less in drama than in the novel—especially in the works of the later Hamsun, of Kinck, of Sigrid Undset and of Olav Duun—and in lyric poetry; drama, with the exception of the later works of Gunnar Heiberg and the plays of Nordahl Grieg, produced by comparison little of conspicuous merit. Throughout the early decades of the century a strong tendency toward regionalism showed itself in a number of ways, particularly but not exclusively in the novel, whereby an author became identified with some particular region or even valley; to emphasize this local connection, many authors deliberately adopted a form of language—either of *landsmål* (later called *nynorsk*) or of *riksmål* (later called *bokmål*)—that was strongly coloured by dialect. The west country was, for example, represented by Jens Tvedt (1857–1935); the east by Hans Aanrud (1863–1953); the south by what was almost a "school," including the brothers Thomas and Vilhelm Krag (1867–1913 and 1871–1933) and Gabriel Scott (1874–1958); and the "middle north" region of Trøndelag by Olav Duun, Johan Bojer (*q.v.*), Peter Egge (1869–1959) and Kristofer Uppdal (1878–1961)—the latter's ten-volume novel-cycle *Dansen gjenom skuggeheimen* ("The Dance Through the Shadow World," 1911–24) being one of the most remarkable products of this age. Pervasive, too, was the tendency, again most strongly marked in the novel, to treat the conflicts that arose in Norwegian society from the spread of industrialism—a process to which Norway was subjected rather later than most other European countries, and also rather differently. The most expressly proletarian writer, both by upbringing and by the themes in his works, was the novelist Oskar Braaten (1881–1939); but altogether superior as an artist is Johan Falkberget (1879–) who writes in his novels with understanding, affection, and his ... insight about the miners of Røros in central eastern Norway, especially in *Christianus Sextus* (1927–35) and in *Nattens brød* ("Bread of Night," 1940 *et seq.*).

Two other great figures in the history of the novel in the first half of the century were Sigrid Undset (*q.v.*), who won the Nobel prize for literature in 1928, and Olav Duun (*q.v.*). Though the setting of Miss Undset's novels ranges in time from the late Middle Ages to the 20th century, their general concern is to examine the whole problematic range of women's loyalties within the framework of their role in society and at various times in history. ... her historical novels, the three-volume *Kristin Lavransdatter* (1920–22; Eng. trans. 1923–27) is one of the undisputed masterpieces of Norwegian literature; the later *Olav Audunssøn* (4 vol. 1925–27; trans. as *The Master of Hestviken*, 1928–30) is generally thought less successful. Of her modern novels, the early *Jenny* (1911) is forcefully realistic; the later ones, including *Gymnadenia* (1929; *The Wild Orchid*, 1931) and *Den brændende busk* (1930; *The Burning Bush*, 1932), were written after her conversion to Roman Catholicism, and bear the clear imprint of this conversion. Duun's masterpiece is his *Juvikfolke* (1918–23; *The People of Juvik*, 1930–35), a novel cycle in six volumes in which he follows the fortunes of a Trøndelag family through the century beginning with Norway's independence from Denmark and ending with World War I; his strength as a novelist lies chiefly in his profound understanding of the deeper sources of human conduct, and in his penetrating insight into life as an endless conflict.

In the years immediately before World War I, several lyric poets of merit made their debut: the easily spontaneous Herman Wildenvey (1886–1959), the disciplined and reflective Olaf Bull (*q.v.*), the dramatically intense Tore Ørjasæter (1886–), and the mystical *landsmål*-poet Olav Aukrust (1883–1929). Between World Wars I and II, however, it was more particularly the socially committed writers who impressed their personalities on the age, particularly the poet Arnulf Øverland (*q.v.*), whose poems of this period showed a steady drift toward the polemical; the novelist and critic Sigurd Hoel (1890–1961); and the dramatist and critic Helge Krog (1889–1962). Another distinguished "engaged" author of these years (though of a slightly later generation) was Nordahl Grieg (*q.v.*), who was killed in World War II.

After the war, a number of writers who had already created something of a reputation for themselves before 1940 further consolidated and enhanced their position. Tarjei Vesaas (1897–), a *nynorsk* novelist and poet widely regarded as the heir to Olav Duun, wrote a remarkable series of novels, beginning with the highly symbolic *Huset i mørkret* ("House in Darkness," 1945) and including *Bruene* ("Bridges," 1966); Cora Sandel (pseudonym of Sara Fabricius, 1880–), who had made her first major contribution to literature with her *Alberte* trilogy (1926–39; Eng. trans. 1962–65), continued to write after the war, as did Aksel Sandemose (1899–1965), Danish by birth but Norwegian by adoption, an experimental writer whose novels of the 1930s many people found shocking; and Johan Borgen (1902–), whose most accomplished early work was probably his short stories, and who made a new reputation with his *Lillelord* trilogy (1955–57) and with the autobiographical *Barndommens rike* (1965).

NORWICH, ALFRED DUFF COOPER, 1st Viscount (1890–1954), British author and politician who, as first lord of

the admiralty (1937–38), ordered the mobilization of the British fleet during the Czech crisis of Sept. 1938. The agreement the British and French governments made with Hitler and Mussolini at Munich a few days later met with his strong disapproval and he resigned from Neville Chamberlain's government on Oct. 1, 1938. When Winston Churchill formed his wartime coalition government in May 1940, Duff Cooper returned to office. His knowledge and love of France secured him the appointments as British envoy to the French Committee of National Liberation in north Africa (Nov. 1943–Sept. 1944) and as ambassador extraordinary and plenipotentiary to France (Sept. 1944–Oct. 1947). He was knighted in 1948, and was created a viscount in 1952.

Duff Cooper was born in London on Feb. 22, 1890, and educated at Eton and at New college, Oxford, before entering the foreign office. During World War I he was commissioned into the Grenadier guards (1917), served with them in France and was decorated (1918). In 1919 he married Lady Diana Manners, daughter of the 8th duke of Rutland (whose beauty became famous through her appearance in the leading role in Max Reinhardt's spectacle, *The Miracle*). The measure of the Duff Coopers' devotion was given most movingly by Duff Cooper in his autobiography, *Old Men Forget* (1953). Having entered politics, he was Conservative member for Oldham from 1924 to 1929, when he lost the seat. He reentered parliament in March 1931, as the victor in a stormy by-election in the old St. George's division of Westminster, a seat he held until 1945. He fought the by-election in 1931 as champion of Stanley Baldwin, who was then the object of a violent newspaper attack. While in parliament Duff Cooper held various ministerial offices. He was respected but failed to endear himself to the house. Indeed, he probably never tried to do so. He wrote several books of which the best is *Talleyrand* (1932), a biography of the French statesman. *The Rainbow Comes and Goes* (1958), *The Light of Common Day* (1959) and *Trumpets From the Steep* (1960) are the three volumes of his wife's autobiography. He died at sea near Vigo, Spain, on Jan. 1, 1954. (J. F. B.)

NORWICH, GEORGE GORING, Earl of (1585–1663), English royalist who played a prominent part in the second phase of the English Civil War, was the son of George Goring of Hurstpierpoint and Ovingdean, Sussex. Knighted in 1608, he became a favourite with James I and his court. He accompanied Prince Charles to Spain in 1623 and later helped to negotiate his marriage with Henrietta Maria. He was made Baron Goring in 1628 and a privy councilor in 1639. He benefited from monopolies granted by Charles I, including those for gold and silver thread, for tobacco, and for the licensing of taverns. As the rift widened between Charles and parliament, Goring devoted himself and his fortune freely to the royal cause. He went with the queen to the Netherlands to raise money for the king in 1642 and, as ambassador to France, he negotiated with Mazarin for money and arms in 1643. These proceedings were revealed to parliament in Jan. 1644 by an intercepted letter to Henrietta, and Goring prudently remained abroad until 1647, when he received a pass from the parliament under the pretext of seeking reconciliation. In Nov. 1644 the king had renewed for him the title of earl of Norwich previously held by his uncle.

Goring had little success as a military commander. The Kentish levies, which he led, were dispersed by Fairfax at Maidstone in June 1648. Then, having failed to raise royalist support in London, he moved into Essex but was besieged in Colchester until compelled by starvation to surrender unconditionally (Aug. 1648). He was condemned to death on March 6, 1649, but, partly because of petitions for mercy, the house of commons reconsidered Norwich's case, and his life was spared by the speaker's casting vote. He next joined the exiled court of Charles II, who employed him to negotiate with the duke of Lorraine for a marriage between the duke's daughter and the duke of York, and for help toward an expedition to Ireland. Norwich had, however, no more success as a diplomatist than as a general. He became captain of the king's guard at the Restoration, and in consideration of the fortune he had expended in the king's service a pension of £2,000 a year was granted to him. He died at Brentford on Jan. 6, 1663, and was buried in Westminster abbey. (S. R. Bt.)

NORWICH, a cathedral and university city, county and parliamentary borough, and county town of Norfolk, Eng., on the navigable river Wensum, 20 mi. W. of the east-coast seaport of Great Yarmouth and 111 mi. N.E. of London by road. Pop. (1961) 119,904.

In the middle of the city lies the market place (markets held twice a week), overlooked by the red-brick City hall (1938), centre of administration and housing the civic regalia; the flint Guildhall (1407–13) with its Tudor council chamber; and the magnificent 15th-century parish church of St. Peter Mancroft, where Sir Thomas Browne (1605–82), author of *Religio Medici*, is buried. Prominent on a mound to the east is the castle (12th century, refaced 1833–39) and since 1894 the principal museum and art gallery. It is particularly rich in archaeology and paintings of the Norwich school; outstanding are the Colman family's gift collections of John Crome (1768–1821) and John Sell Cotman (1782–1842). On low ground near the Wensum stand the cathedral and remains of the Benedictine monastery founded (1096) by Bishop Herbert de Losinga two years after the ancient see, founded by St. Felix, had been moved from Thetford. The cathedral church of the Holy Trinity is largely 12th century, with a distinctive Norman apse and nave, enhanced by Perpendicular and other additions; it is 461 ft. long. The roof of the nave was built by Bishop Walter Lyhart (1449–72) to replace a wooden roof, and that of the chancel by Bishop James Goldwell (1472–99) who also built the lofty stone spire, 315 ft. high. The many treasures of the cathedral include the pre-Norman bishop's throne, the only example north of the Alps of a throne in the ancient basilican position and still used by Herbert's successors, numerous painted bosses, 14th-century examples of local painting and well-preserved 14th–15th-century cloisters, the largest in England. The extensive precincts are entered from the ancient fairground of Tombland by the richly sculptured Erpingham gate (1420) and St. Ethelbert's gate (1316). Life's green in the precincts contains the grave of Nurse Edith Cavell (*q.v.*). South of the City hall stands the Central Public library (1963), a rectilinear building of flint, glass and concrete containing an American library, and a courtyard fountain, given by the 2nd Air division, 8th U.S.A.A.F., in memory of the 6,032 members who lost their lives 1941–45; there also are the Colman and Rye libraries of local history (40,000 volumes), the City library (1608) and the Norfolk and Norwich Record office. Adjacent are the Assembly rooms, the finest example of Georgian architecture in Norwich, built by Thomas Ivory (1754), now a municipal cultural centre. Among the city's 30 medieval churches are St. John Maddermarket, rich in memorials to great Norwich citizens including Nugent Monck (1878–

KENNETH SCOWEN

ELM HILL, A SIDE STREET IN NORWICH

1958), founder of the nearby Maddermarket theatre; St. Andrew's church in which parish Anthony Solen established the first Norwich printing press (1567) and where, about 1602, John Robinson, pastor to the Pilgrim Fathers, troubled the church by his radical puritanism; and the rebuilt Saxon church of St. Julian, with a modern chapel dedicated in memory of Julian of Norwich, the 14th-century anchoress and mystic who wrote the *Revelations of Divine Love* there. St. Andrew's hall, which takes its name from the neighbouring church, is the nave of the former church of St. John the Baptist, built by the Dominicans in the 15th century. Later it housed the Dutch congregation and is now an exhibition and concert hall. Nearby are three municipal museums, the mainly medieval Strangers' hall (domestic life), the 14th-century flint Bridewell (local industries) and St. Peter Hungate church (ecclesiastical museum). Significant in the history of nonconformity are the Congregationalist Old Meeting house (1693), the Unitarian Octagon chapel (Thomas Ivory, 1754) and the Quakers' Gildencroft (1699, rebuilt).

Fast railway passenger and freight services link Norwich with London (two hours), the east coast and the midlands. The river port, taking ships up to 600 tons, with 400 ft. of public quay and a yachting station for pleasure craft, imports coal, timber and grain. A new 35-ac. livestock market was opened in 1960; with the city's corn, vegetable and provision market, and 1,500 retail shops, it serves a large agricultural hinterland. Norwich ranks high among English cities in the making of footwear, which employs 9,000 workers and exports to western Europe and the Commonwealth. Other main industries with an export trade are the manufacture of wire netting, packing machinery, heating-plant and electric motors, and the production of mustard, soft drinks and confectionery; insurance, banking and printing are also important. Norwich was subjected to a series of heavy air attacks during World War II and since then extensive rebuilding and town planning have taken place.

Schools include the Grammar school, founded by Edward VI although there was previously a monastic school on that site. George Borrow and Horatio Nelson were pupils. Establishments for advanced education include a teachers' training college, an art school, and the City college which attracts students from all parts of the Commonwealth; in 1963 the University of East Anglia was opened in the pastoral setting of Earlham park, long associated with the Gurneys, a Quaker family of bankers and social reformers, among whom was Elizabeth Fry. Prominent features of the city's cultural life are the Archaeological society, Philharmonic society, Art circle and the Maddermarket theatre. The Norwich festival of choral music and the arts is held triennially. There are two television broadcasting stations. Increasingly Norwich attracts tourists both for its own interest and as the approach to the Norfolk coast and the system of lakes known as the Broads.

The first permanent settlements on the site were Saxon villages on the gravel terraces above the Wensum, three miles north of the site of the Roman town of Venta Icenorum (Caistor St. Edmund). One of them, Northwic, where coins were minted (925–940) by Aethelstan, gave its name to the subsequent town, already a thriving trading centre when sacked by the Danes (1004). By the Norman Conquest it had 5,500 inhabitants and during the next seven centuries was one of the most prosperous of English provincial towns; by 1662 it was probably the largest with nearly 30,000 inhabitants. The surrounding fertile country provided timber, hides, grain and wool (stone was brought from overseas) and sustained the early building, leather, brewing and woolen industries, which were financed by a prosperous 12th-century Jewish community. Enormous impetus was given to the wool trade when Edward III induced Flemish weavers to settle in 1336, and again when Dutch, Flemish and Walloon Protestant refugees came in the reign of Elizabeth I. In 1579 there were 6,000 foreigners in a population of 16,000. A generation later many Norfolk Puritans left to found townships in the new American colonies. In 1643, at the time of the Civil War, the Puritans were dominant, churches and the cathedral were sacked, and Bishop Joseph Hall was forced to leave his palace.

Recurrent outbreaks of bubonic plague, particularly severe in 1349, 1579 and 1665, destroyed a third of the population. Unsuccessful peasant revolts were led by John Litester (1381) and Robert Ket (Kett) (1549). The first charter dates from 1158 and a second charter was given by Richard I in 1194. Henry IV's charter of 1404 made Norwich a county, with a mayor and two sheriffs. It became a county borough in 1888 and the title and dignity of Lord Mayor was bestowed upon the chief magistrate in 1910. Since 1298 it has returned two members to parliament.

Pevsner, *The Buildings of England: North-East Norfolk and Norwich* (1962); W Hudson and J. C. Tingey, *Records of the City of Norwich*, 2 vol. (1906–10).

(F. D. SA.)

NORWICH, a city of southeastern Connecticut, U.S., is located 13 mi. N. of New London, at the confluence of the Yantic and Shetucket rivers which there form the Thames; one of the seats of New London county. Norwich is accessible to the sea by way of a Thames river channel capable of handling ships up to about 10,000 tons. Shipbuilding and shipping were important in the 18th century, and from the American Revolution to the American Civil War firearms were made there. Subsequently, however, Norwich became an important centre for the manufacture of textiles, vacuum bottles, metal and leather products, machinery paper boxes, clothing, plastics and chemicals.

The town was founded in 1659 by settlers from Saybrook under the leadership of Capt. John Mason and the Rev. James Fitch. The land was purchased from Uncas, a Mohegan chief and an early friend of the settlers, who is buried under a monument on Sachem street. The city, part of the town of Norwich which also included Norwichtown, Taftville and part of Yantic, was chartered in 1784. In 1951 the city and the town were consolidated and a council-manager form of government was inaugurated.

Norwich is the birthplace of Benedict Arnold and the home of the Huntington family, many members of which were leaders in early American civil and military affairs. Many houses dating from the 17th and 18th centuries still stand. These include the Leffingwell inn (1666) and the Glebe house (1748). Pop. (1960) 38,506; for New London–Groton–Norwich standard metropolitan statistical area *see* NEW LONDON. For comparative population figures *see* table in CONNECTICUT: *Population*. (W. D. LO.)

NORWID, CYPRIAN KAMIL (1821–1883), the most original and least appreciated Polish poet of the 19th century, whose works have been rediscovered in the 20th century and have influenced modern Polish writers, was born at Laskowo-Gluchy near Warsaw, on Sept. 21, 1821. In 1837 he began to study drawing and painting; and in 1842 set out for Italy. In 1846 after an incident with the Russian envoy in Berlin, he was arrested and, on his release, deported to Belgium. He went to Rome again in 1847 and to Paris in 1849. In 1852 he sailed for the United States but in 1855 returned, via England, to Paris, where he led a life of penury and obscurity and where he died on May 22, 1883.

His lack of literary success in his own day was due to the idiosyncratic and difficult style of his many writings in prose and verse—poems (*Poezye*, 1863), plays (*Krakus*, publ. 1863; *Wanda*, publ. 1901; *Kleopatra*, publ. 1904) and treatises (*e.g.*, *Promethidion*, a treatise on aesthetics, in prose and verse, included in *Poezye*) His poetry is essentially philosophical. It shows profound understanding of history, respect for the individual, a fine sense of irony, intellectual integrity and a self-effacing subordination to his subject which results in the utmost verbal economy. Norwid's work was restored to posterity by Zenon Przesmycki (Miriam) who began publishing his works in 1901. For portrait *see* article POLISH LITERATURE.

See J. Pietrkiewicz, "Introducing Norwid," *The Slavonic and East European Review*, vol. xxvii (1948); translations of Norwid's letters and poems in *Botteghe Oscure*, vol. xxii (1958). (L. R. LA.)

NORWOOD, a city of Hamilton county in southwestern Ohio, U.S., is completely surrounded by the city of Cincinnati (*q.v.*). Norwood, originally Sharpsburg after John Sharp, one of its earliest settlers, began as a crossroads coach stop in 1809. Its position on the upland between the Great and Little Miami rivers, away from the early major routes of commercial travel, resulted

in very slow growth compared to nearby valley cities. It was laid out in 1873, incorporated as a village under its present name in 1888 and chartered as a city in 1903. By 1900 it had become a minor railway centre and residential suburb, especially for merchants of Cincinnati. Soon after, it began attracting industries that wished to locate in Cincinnati but found the larger city too crowded. Leading industries include printing and lithographing and the manufacture of automobiles, automobile bodies, paints, machine tools, electric motors, playing cards, women's shoes, office equipment, laundry machinery and cans. Norwood is the seat of Athenaeum of Ohio, a Roman Catholic college for men, founded in 1829 as the Seminary of St. Francis Xavier. For comparative population figures on Norwood (part of the Cincinnati standard metropolitan statistical area) *see* table in OHIO: *Population.*

(J. L. TH.)

NOSE, the organ of the sense of smell in man and other animals; it also acts as a filter and a warmer for inspired air.

See OLFACTORY SYSTEM; SMELL AND TASTE.

NOSE, DISEASES OF. Diseases of the nose lead to dysfunction, characterized chiefly by impaired nasal breathing. The primary function of the nose is to serve as an air conditioner for all the inspired air before it reaches the lungs, but the nose also serves as an organ of smell, the olfactory sense.

Diseases of the nose are subdivided into acute and chronic rhinitis (rhinitis meaning an inflammatory reaction of the mucous membrane lining of the nose). In the acute form, such as a head cold (*see* COLD, COMMON), rhinitis is accompanied by a profuse watery discharge, which always impairs nasal breathing. Unless secondary infection occurs, these symptoms last for a period of usually seven days. Allergic rhinitis, which produces similar symptoms, may be caused by any allergen, such as ragweed or dust, and is commonly called hay fever (*q.v.*). The symptoms of this condition persist and do not subside until the offending allergen is discovered and removed. Chronic rhinitis, which usually is due to repeated attacks of acute rhinitis, produces in the early stages hypertrophy or enlargement of the mucous membrane, termed hypertrophic rhinitis. The hypertrophy leads to impairment of nasal breathing and usually is accompanied by a thick, tenacious discharge. If this condition persists for a long period of time it is followed by atrophy and the presence of dry offensive-smelling crusts, a condition called atrophic rhinitis.

Impairment of nasal breathing frequently is occasioned by irregularities or deformities of the central partition of the nose (nasal septum), occurring as a general rule as the end result of external injury to the nose. The tip and nasal vestibule of the nose are prone to staphylococcus infection because of the presence of hair follicles inside the nose.

Continued irritation from infection or allergy can give rise to nasal polyps, usually on the middle turbinate. Gradual enlargement of these polyps leads to increasing difficulty in breathing through the nose. *See* also NOSEBLEED; SINUS.

See W. W. Morrison, *Diseases of the Ear, Nose and Throat* (1948); R. L. Cecil and R. F. Loeb (eds.), *A Textbook of Medicine*, 10th ed. (1959).

(G. W. McA.)

NOSEBLEED (EPISTAXIS) is common and usually of little importance in childhood. It may result from local conditions or inflammation, small ulcers or polypoid growths, or severe injuries to the skull. Vascular disease, such as high blood pressure, may provoke it, and such diseases as scurvy and hemophilia also may be responsible for it. Usually it is easily controlled by rest, application of cold and pressure. On occasion it may require expert care.

(F. L. A.)

NOSTRADAMUS (1503–1566), a French astrologer of Jewish descent, who is still remembered for his prophecies. His real name was Michel de Notredame or Nostredame, and he was born at St. Rémy in Provence on Dec. 14, 1503. At Avignon he studied philosophy, and then at Montpellier he read medicine, graduating in 1529. He first practised at Agen, and in 1544 established himself at Salon, near Aix, where he became noted for fine work during outbreaks of the plague at Aix and Lyons.

Nostradamus began to make his prophecies about 1547, publishing at Lyons in 1555 a book of rhymed prophecies entitled *Centuries*. Astrology was at a peak at this time, and an enlarged second edition, dedicated to the king, was published in 1558. The *Centuries* consisted of quatrains grouped in hundreds, each set of quatrains being called a century.

Some of Nostradamus' prophecies seemed to have become fulfilled, and his fame became such that he was invited to visit Catherine de Médicis and himself received the duke of Savoy at Salon. Charles IX appointed him physician-in-ordinary. He died on July 2, 1566, but his predictions were eagerly read for long after. Much controversy has been aroused because of the indefinite nature of their meaning, and some have been believed to foretell the distant future. The famous 33rd quatrain of the 5th century, *e.g.*, has been interpreted as a prophecy of the "drownings" of Nantes under the Committee of Public Safety, 1793:

> "Des principaux de cite rebelle
> Qui tiendront fort pour liberte r'avoir,
> Detrancher masles, infelice meslee
> Cris, hurlemens a Nantes piteux voir."

That is: "The city's leaders in revolt, will in the name of liberty slaughter its inhabitants without regard to age or sex. There will be screams and howls and piteous sights in Nantes." (*See* CARRIER, JEAN BAPTISTE.) The prophecies have been the subject of many commentaries, but in 1781 they were condemned by the Congregation of the Index, the body set up by the Roman Catholic Church for the examination of books and manuscripts.

See E. Bareste, *Nostradamus* (1840); C. A. Ward, *Oracles of Nostradamus* (1891); E. Leoni, *Nostradamus: Life and Literature* (1961).

(CH. A. R.)

NOSY BE (NOSSI-BÉ; Be, "great," Nosy, "island"), a volcanic island about 8 mi. off the northwestern shore of the Malagasy Republic (Madagascar), is 19 mi. long and 12 mi. wide with an area of 129 sq.mi. Pop. (1956) 25,787. It has numerous craters and crater lakes and its highest point is Mt. Passot (1,079 ft.). The climate is hot and damp with temperatures ranging from 35° to 18° C. (95° to 64° F.) and a rainfall of 78 to 118 in. a year. Nosy Be is an island of sugarcane and aromatic plants, with forests containing lemurs, a great variety of birds, strange spiders and an endemic frog. Its chief products are sugar and essential oils for perfumery. It also produces rum, quality cacao, vanilla, black pepper, and bitter oranges. The chief town and capital is Hellville, on a sandy bay on the southern shore. It is a seaside resort, a port of call for the Messageries Maritimes (foreign services shipping line), with excellent anchorage, a centre for the coasting trade along the western shores of Madagascar, and the river port for Ambanja on the mainland opposite. There is an airfield at Fascène (7 mi.).

The arrival of Captain Passot's warship "Colibri" in 1840 was the first step in the cession of the island to the French. A treaty of protection was signed between Queen Tsioméko and Captain Passot and the latter named the town Hellville after his commander in chief, Admiral de Hell. Some houses dating from that time are the only curiosities in a town built of iron-roofed bungalows and with no outstanding features. The island is part of Majunga province and has been administered from Madagascar since 1896.

(J. AR.)

NOTARY (NOTARY PUBLIC), a public official whose chief function is to authenticate contracts, deeds and other documents by an appropriate certificate to which is attached the notarial seal.

In Roman law the *notarius*, from which the modern term comes, was originally a slave or freedman who took notes of judicial proceedings in shorthand. The work of the modern notary, however, corresponds more to the Roman *tabularius*, who took and preserved evidence. In medieval times the notary was an ecclesiastical officer nominated by a church official to preserve evidence by attesting important documents. His duties were, and are, mainly secular.

The notary is today appointed by a secular official such as a governor or a president of a republic. This appointment is usually made on application and becomes effective on payment of a fee, the taking of an oath of office and, in many parts of the United States, on deposit of a bond with sureties conditioned upon the proper performance of his duties.

In the United States, qualifications for the position of notary vary little from state to state. In general, a notary must be a citizen of legal age, a resident of the place in which he desires appointment and a person of good moral character. In about 12 states of the United States a woman may not qualify for the position. In countries such as France and Italy and in Quebec, Canada, which follow the civil-law tradition, there are educational requirements similar to those for lawyers and other professions.

In the United States a special jurisdictional problem exists for notaries. The jurisdiction of the notary's office is a state or, in some states, only the county in which he resides; thus, a notary appointed for the District of Columbia may not act in Virginia or in the Maryland suburbs of Washington. If a document is to be used in a county or state in which the notary is not ordinarily qualified to act, a certificate is usually required from an official such as a county clerk showing that the notary is authorized to act in that jurisdiction.

In the civil-law countries of western Europe, including Scotland, and in the Latin-American and French areas of North America, the office of notary is a much more important position than in the United States and England. In these places a notary may be roughly described as a "lawyer" who specializes in the law relating to real estate, sales, mortgages and the settlement of estates but who is not allowed to appear in court. Documents prepared by him or authenticated in the proper manner are, in these countries, admissible in court without further proof of their authenticity. The notary guarantees the identity of the parties.

In the Anglo-American law countries, on the other hand, courts will not accept the facts that a notary has certified as true except in the case of a bill of exchange protested abroad. Nor may a notary draw up legal documents such as wills, contracts, mortgages and deeds for a fee, for such work constitutes the practice of law. Nevertheless, many statutes require that the authenticity of specified documents be certified by a notary, the most common in the United States being those requiring the acknowledgment of a deed conveying land. An acknowledgment is a declaration by the person who has executed (*i.e.*, signed) it that he in fact executed it. It is made before a notary who certifies to that fact and to the identity of the acknowledger. A notary should not, therefore, take the acknowledgment of a person who does not appear before him or from a person who is not known to him unless evidence of identification is presented.

Certain other officials may be given notarial functions by statute, such as justices of the peace, consular officials, certain military officers and various court officials. (A. DM.)

NOTITIA DIGNITATUM, an official list of all offices, civil as well as military, in the eastern and the western halves of the Roman empire. It was one of the duties of a high official, known as the *primicerius notariorum,* to prepare and issue the diplomas of their appointments to all the higher officials of the empire. The insignia of each office were represented on the relevant diploma; and hence the *primicerius* of the west as well as of the east had a list of all the officials in his half of the empire together with information about their subordinates. The surviving *Notitia Dignitatum* happily includes lists of the officials in both parts of the empire and is one of the chief sources of information about the administration, civil as well as military, of the late Roman empire. In addition the *Notitia Dignitatum* gives much geographical knowledge of great value.

The extant manuscripts include copies of the illustrations of the various officials' insignia of office. The problem of the precise date of the document is of great importance and has been much debated. The truth may be that the *Notitia* was drawn up toward the end of the 4th century but was revised and more or less brought up to date in later decades. It was the opinion of J. B. Bury, which has been widely accepted, that the text which survives is a copy of the lists which were in the hands of the *primicerius* in A.D. 427 or not much later. It does not follow, however, that the *Notitia* gives an accurate picture of the administrative hierarchy as it existed in that year. Thus, although the imperial officials in Britain are recorded, it does not follow that Britain was still under Roman administration in 427: these officials would not have been erased from the list unless Britain had been formally ceded to some non-Roman power. They were retained in the record in the hope that the administration of Britain, which seems to have been lost to the empire *c.* 410, would one day be resumed by the emperors. But, when used with care, the *Notitia* is of fundamental importance.

The text was edited by O. Seeck (1876) and it was reprinted in 1962. (E. A. T.)

NOTKER, a name borne by several medieval ecclesiastics. BLESSED NOTKER BALBULUS (*c.* 840–912), "the Stammerer," entered the Benedictine monastery of St. Gall, Switz., and became librarian in 890 and then master of its school. He is known for his composition of sequences, a rhythmic text following the gradual of the Mass, and is commemorated on April 6.

NOTKER (*c.* 940–1008), named bishop of Liège in 972 by his uncle, the emperor Otto I, was active in the reform of his own clergy and that of the abbey of Lobbes, whose Abbot Heriger is the author of the *Lives* of saints attributed to Notker.

NOTKER LABEO (*c.* 950–1022), monk and master of the monastic school at St. Gall, whose translation of sacred and secular Latin texts into Old High German earned him the epithet of "the German." (H. G. J. B.)

NOTORNIS (TAKAHE) (*Notornis hochstetteri*), a chicken-sized flightless gallinule (family Rallidae) of South Island, New Zealand. It is a colourful species with brilliant blue and coppery-green plumage and a large red bill, continued onto the forehead in a frontal shield. Considered extinct for 50 years, the notornis was rediscovered in 1948, living in small groups in several remote, thickly wooded glacial valleys at 2,000 ft.

It is a browsing species, stripping seeds from grasses by running the bill along the stems. The nest is on the ground and the two eggs are dull cream with brown blotches; the young are black and downy. Both parents are believed to share in the incubation, and the young may be able to breed at the age of one year. See also RAIL. (W. J. BE.)

NOTRE DAME, UNIVERSITY OF, a Roman Catholic institution of higher learning for men, at Notre Dame, Ind., was founded in 1842 by brothers of the Congregation of Holy Cross, a religious community that originated in France. *See* SOUTH BEND.

NOTTAWAY, a river of western Quebec, Can., drains Lake Mattagami at 765 ft. above sea level and flows northward 140 mi. into Ruperts bay at the south end of James bay. Many rivers flow into Lake Mattagami, the largest being the Bell, Chibougamau and Waswanipi, and each adds over 150 mi. to the main stream. The swift-flowing Nottaway with its many rapids and falls was explored by Robert Bell, Canadian government geologist, in the 1870s. (J. D. I.)

NOTTINGHAM, EARLS OF. This English title was created in 1377 for JOHN DE MOWBRAY (1365–1383), and after his death it was recreated in 1386 for his brother and heir, THOMAS (*c.* 1366–1399), who became duke of Norfolk in 1397 (*see* NORFOLK, THOMAS MOWBRAY, 1st Duke of). The earldom remained a subsidiary title in the Mowbray family until the death of JOHN (1444–1476), 4th duke of Norfolk. It was then recreated for RICHARD (d. 1483), duke of York (*see* YORK, RICHARD, Duke of), who was murdered in the Tower of London, and the title was then granted in 1483 to WILLIAM DE BERKELEY (d. 1492), on whose death the title lapsed. HENRY FITZROY (*c.* 1519–1536), an illegitimate son of Henry VIII, held the title as a subsidiary honour to the dukedom of Richmond. On his death without heir, the earldom reverted to the crown until it was re-created for CHARLES HOWARD (*c.* 1536–1624), Lord Howard of Effingham (*see* NOTTINGHAM, CHARLES HOWARD, 1st Earl of). On the death of CHARLES (1610–1681), 3rd earl of this line, the earldom became extinct but the barony of Effingham passed to his cousin and heir male.

HENEAGE FINCH (1621–1682), the lord chancellor, was created earl of Nottingham a few months before his death on Dec. 18, 1682. The Finch family was of Kentish origin, and Thomas Finch (d. 1563) was knighted for his part in suppressing Sir Thomas

Wyat's rebellion in 1554. His son, Sir Moyle Finch (d. 1614), married Elizabeth, daughter of Sir Thomas Heneage; she was created countess of Winchilsea in her own right in 1628. Her fourth son, Sir Heneage Finch (d. 1631), a distinguished lawyer, was speaker of the house of commons, recorder of the City of London and the father of Heneage Finch, the lord chancellor. The latter was called to the bar in 1645, appointed solicitor general at the Restoration, attorney general in 1670 and lord chancellor in 1675. He was created baron in 1674 and earl of Nottingham in 1682.

DANIEL (1647–1730), 2nd earl, took a prominent part in politics after 1688 and was secretary of state 1688–93 and 1702–04. He was a Tory who had considerable influence over Mary II, but suspicion of Robert Harley and Henry St. John led him to join the Whigs in 1711. In 1729 he inherited the earldom of Winchilsea, and thereafter the earldom of Nottingham was merged in the Winchilsea title. The earldoms passed in 1826 to GEORGE (1791–1858), 10th earl of Winchilsea and 5th earl of Nottingham, who adopted the additional surname of Hatton. CHRISTOPHER (1936–), 11th earl of Nottingham and 16th earl of Winchilsea, succeeded in 1950.

NOTTINGHAM, CHARLES HOWARD, 1ST EARL OF, and 2ND BARON HOWARD OF EFFINGHAM (1536–1624), English lord high admiral who commanded the fleet in the defeat of the Spanish Armada. He was the eldest son of William, 1st Baron Howard of Effingham, lord high admiral. He was closely connected with Elizabeth I, since his father's sister, Elizabeth Howard, was the mother of Anne Boleyn. He was sent as ambassador to France in 1559 to congratulate Francis II on his accession and was general of the horse under the earl of Warwick in suppressing the rebellion of the north in 1569. Next year he commanded a squadron sent to watch the Spanish fleet which came to conduct the queen of Spain from Flanders. In the parliaments of 1563 and 1572 he represented Surrey. He succeeded to his father's title of Lord Howard of Effingham in 1573; was installed a knight of the Garter in 1575; and made lord chamberlain of the household in 1584, an office he retained until he became lord high admiral in 1585. He was one of the commissioners for the trial of the conspirators in the Babington plot and of Mary Stuart in 1586.

When the English naval forces were mobilized against the Armada, Howard hoisted his flag as commander in chief on the "Ark" in Dec. 1587 and in May 1588 sailed with the main fleet from the river Thames to join Sir Francis Drake's advance force at Plymouth. Drake became his vice-admiral and John Hawkins his rear admiral. These two, with five other officers, formed his council of war and the harmony that his personality and authority imposed upon his more brilliant subordinates was an important factor in the victory. Like them, he was eager to seek out the Spanish fleet upon its own coasts. But when he at length won Elizabeth's consent, adverse winds thrice frustrated him and while he was refitting in Plymouth after the third attempt, the Armada appeared off the Lizard (July 19). In the ensuing actions, the English ships outsailed and outmaneuvered the enemy, but Howard, at first probably outnumbered and even outgunned (for short-range fire), did not dare to close with them. Instead, he harassed them from longer range, plucking "their feathers by little and little," and shepherding them slowly up the English channel. Rasher spirits criticized these tactics, but, as Sir Walter Raleigh said, "had he entangled himself with those great and powerful vessels, he had greatly endangered this kingdom of England." He was perhaps more open to criticism for lagging behind the rest of the fleet to attack the crippled "San Lorenzo" at Calais on July 29, at a moment when the Armada, its close formation broken by the English fireships, was straggling in disorder past Gravelines. Nevertheless, he contributed nobly to a famous victory and his fame hardly needed the support of the rather one-sided "Relation of Proceedings," published in *State Papers Relating to the Defeat of the Spanish Armada*, ed. by Sir J. Laughton for the Navy Records society (1894), drawn up at his direction. (*See* ARMADA.)

Howard's next important service was the expedition of 1596 to Cadiz, which he commanded jointly with the earl of Essex. Supported by the council of war, he rejected Essex' proposals for further operations after the capture of the town and the next year Essex' anger was increased when the queen created Howard earl of Nottingham (Oct. 1597). Nottingham was again busy with preparations against invasion in Feb. 1598; and also in the summer of 1599, when he was given the exceptional office of lord lieutenant general of England. In 1601 he took a leading part in suppressing Essex' rebellion and served as a commissioner at his trial. It was to Nottingham that Elizabeth named James I as her successor on her deathbed.

Under the new king Nottingham continued in his office of lord high admiral. He was one of the commissioners to treat with Spain in 1604 and went as ambassador extraordinary to receive the Spanish ratification of the peace treaty in 1605. He served on numerous commissions, including those on the union of England and Scotland in 1604, for the trial of the conspirators of the Gunpowder plot and of the Jesuit Henry Garnett in 1606, and for reviewing the articles and rules of the order of the Garter in 1611 and 1618. He attended Princess Elizabeth to Flushing with a squadron on her marriage to the elector palatine in 1613. Nottingham, who, unlike many of the Howards, was a stanch Protestant, was commissioner in Surrey for inquiring after recusants, and in the diocese of Winchester for hearing ecclesiastical causes; he sat on the government commission for discovering and expelling Roman Catholic priests, and was mentioned in 1602 from Douai as one of the three enemies most feared by the recusants. On the report of the commission on the navy in 1618, Nottingham, who was over 80, vacated his office of lord high admiral (Jan. 1619), though no blame was attached to him for the abuses then exposed.

He died at Haling house, near Croydon, Surrey, on Dec. 14, 1624, and was buried at Reigate, a monument being later placed to his memory in St. Margaret's church, Westminster.

Nottingham married first, in 1563, Catherine, daughter of Henry Carey, 1st Lord Hunsdon; and secondly, in 1603, Margaret, daughter of James Stuart, earl of Murray. Charles (1579–1642), his second son by his first marriage, succeeded as second earl of Nottingham. On his death without male issue, he was succeeded by his half brother, and when he died childless in 1681 the earldom became extinct. (R. B. WM.)

NOTTINGHAM, a municipal, parliamentary and county borough (1888), the county town of Nottinghamshire, Eng., stands on the river Trent 123 mi. N.N.W. of London by road. The town was raised to the status of a city in 1897 and the title and dignity of lord mayor was conferred in 1928. Pop. (1961) 311,899.

The main feature of the city is the Old Market square, 5½ ac. in extent, one of the largest in England and which has existed from Norman times. Dominated on the eastern side by the Council house, opened in 1929 replacing the earlier Exchange building of 1726, the square is flanked by shops with a central area reserved for pedestrians.

Nottingham is linked with the Robin Hood folk legend, commemorated in the Robin Hood statue by James Woodford on the Castle green. In the Low Pavement and Castle Gate are some fine examples of 18th-century houses. It was at Standard hill that King Charles I raised his standard in 1642, marking the outbreak of the English Civil War. The castle was demolished in 1651 on the orders of parliament. William Cavendish, the 1st duke of Newcastle, built on the site in 1674 a town mansion, which was burned during the Reform Bill riots of 1831; the burned-out shell was acquired and renovated by the corporation (1875–78) and now houses the museum and art gallery.

The oldest parish church is St. Mary's, a mainly Perpendicular cruciform structure with a fine central tower. St. Peter's dates from the 12th–15th centuries. St. Nicholas' was rebuilt in 1678 after it had been demolished by the Parliamentarians during the Civil War. Nearby in Castle Gate is Newdigate house (1670), where the French Marshal Tallard, who was taken prisoner at the battle of Blenheim (1704), lived. The Roman Catholic cathedral of St. Barnabas, designed by Augustus Pugin, was consecrated in 1844.

The grammar school, founded in 1513 by the benefaction of Dame Agnes Mellors, moved in 1868 to its present buildings on Arboretum street, and is known as the High school. The Notting-

ham High School for Girls (1875) is one of the Girls' Public Day School Trust foundations. University college was opened in 1881 and was moved to its present site of more than 260 ac. on Highfields in 1928, the land being given by Lord Trent (Jesse Boot, founder of Boots Pure Drug company). The university was incorporated in 1948 and began to confer its own degrees in 1950. The old University college buildings on Shakespeare street now house the Nottingham and District Technical college. The Theatre Royal on Theatre square (1865) replaced an earlier theatre built in 1760 in St. Mary's Gate. A new Civic theatre was opened in 1963. Trent Bridge cricket ground, one of the finest in the country, is the home of Notts County Cricket club.

The Arboretum was opened as a park in 1852. The Elizabethan Wollaton hall, together with its park of 744 ac., was bought by the corporation in 1925. The hall houses the Natural History museum. Newstead abbey (11 mi. N.W. of the city), a 12th-century Augustinian priory converted into a residence in 1540 and the ancestral home of Lord Byron, is owned by the corporation and contains the Roe-Byron collection. The grounds are also open to the public.

The Trent is navigable as far as Nottingham for barge traffic. The city is linked by a two-hour rail service with London, and is a centre of main roads.

Nottingham is in the heart of the east Midland coalfield, and there are three collieries within the city boundaries. Frame knitting as a trade was important there by the close of the 17th century and with the inventions of spinning machinery by Richard Arkwright and James Hargreaves, Nottingham became a centre for the hosiery trade, which it still is. It was famous for the making of lace and although this trade has declined its lace is still in demand as a fashion fabric. There are allied industries of dyeing and bleaching and much knitted wear is manufactured.

Nottingham has important pharmaceutical and tobacco industries and is the location of one of the largest bicycle plants in the world. Many other trades are carried on, notably light engineering, brewing and furniture manufacture, forming a diversified economy which has given the city continuous prosperity.

The settlement probably grew up because at this point an ancient highway crossed the Trent. The Anglo-Saxons, who occupied the site in the 6th century, gave the settlement the name of Snotingaham, the ham or village of Snot's people. Occupied by the Danes in the 9th century, it was one of five towns of the Danelaw and in pre-Conquest times was known as a city. After the Conquest the Normans founded the Norman borough which existed side by side with the older Saxon borough, both having separate administrations until about 1300. Nottingham's first known charter (1155) confirmed to the burgesses the liberties they had held under Henry I, referred to a market on Saturdays and forbade the working of dyed cloth, except in Nottingham, within ten leagues of the borough. King John confirmed this and granted a guild merchant. Henry III allowed the burgesses to hold the town in fee farm, and Edward I granted them a mayor and two bailiffs. Henry VI in 1449 confirmed all preceding privileges, first incorporated the mayor and burgesses, instituted the office of sheriff and granted that the town, except the castle and jail, should be a county of itself. Parliaments were held at Nottingham in 1334, 1337 and 1357, and it was the scene of the conference of the judges with Richard II in 1387. In the course of its history several fairs were granted to Nottingham; one, the Goose fair, is still held for three days in October. In 1815 it was the centre of riots organized by the Luddites (*q.v.*).

Nottingham's literary associations include Byron, D. H. Lawrence, Philip James Bailey, Samuel Butler and Henry Kirke White.

NOTTINGHAMSHIRE, a midland county of England, is bounded north and northwest by Yorkshire, west by Derbyshire, south by Leicestershire and east by Lincolnshire. It is roughly oval, 51 mi. long by a maximum of 27 mi. wide, and its geographical area is 859 sq.mi.

Physical Features.—The higher western part of the county forms the eastern fringe of the southern Pennines, and the lower eastern part merges into the lowlands of Lincolnshire. The rocks are sedimentary, and mainly dip gently eastward or southeastward with little disturbance. The Coal Measures are exposed along part of the western border and extend east beneath newer formations to underlie the whole county except a small area in the south. Below the Coal Measures are grits and limestones which in several parts, and notably in the Eakring area near the centre, yield oil. Above the Coal Measures and to the east is a narrow belt of dolomitic or magnesian limestone, with a sharp west-facing scarp, and having the highest land in the county, more than 600 ft. O.D. (Ordnance Datum) near Kirkby-in-Ashfield. To the east again is a belt of Bunter Sandstone, much of which was occupied by the old Sherwood forest. The outcrop is 40 mi. long from Bawtry in the north to Nottingham in the south, and is about 6 mi. wide. The high porosity of the sandstone makes the area almost riverless, and forest and heath is the natural vegetation. Most of east Nottinghamshire consists of Keuper rocks, especially the red Keuper Marl, again forming a west-facing scarp. This area abounds in small streams with comparatively deep valleys, and it is bisected by the vale of the river Trent, covered with alluvial deposits, including patches of river gravel. In the extreme south of the county Keuper and Lias rocks are covered by thick boulder clay which forms the Wolds, rising to about 400 ft. O.D., and extending into Leicestershire.

The river Trent enters the county in the southwest and, curving left, forms the Nottinghamshire-Lincolnshire border in the northeast. Originally the middle Trent drainage discharged eastward via the Ancaster gap, but during the Pleistocene era it flowed through the Lincoln gap for a time, the Trent cutting a shallow trench between Nottingham and Newark-on-Trent and depositing gravels between Newark and Lincoln along a part of its course now abandoned. Its diversion to a still more northerly outlet to the Humber is a comparatively recent development. In the extreme north of the county the Bunter and Keuper rocks decline beneath a low but very fertile alluvial and peat fenland, now artificially drained.

Climate varies little over the county, but because of its situation well to the east in England, Nottinghamshire's range of mean monthly temperature is fairly wide (Jan., 3° C. [38° F.]; July 16° C. [61° F.]). Ground frost occurs on an average of 100-120 days a year, and the Trent vale is especially susceptible to it. The prevailing wind is southwest to west, but cold northeast to east winds are common in spring. The mean annual rainfall varies between 22 in. and just over 30 in., falling evenly both in winter and summer. The mean daily sunshine figure for Nottingham is 3.63 hr., but cloud and fog are frequent in winter, and the December average is only 0.90 hr.

Most of Nottinghamshire is either heavily industrialized and urbanized, or else intensively farmed, but the Sherwood forest area includes large tracts of seminatural vegetation, in the form of oak and birch woods with an undergrowth of bracken interspersed with open areas of heather, ling and gorse. In earlier times the red deer was abundant, and wolf, pine marten, polecat, badger and otter were all common in the forest, but only the last two are still found. More than 150 varieties of birds are still encountered in the county, but many are resident only in the forest area. In 1961 the National trust owned 3,784 ac. in the county. (F. A. BA.)

History.—Implements of Paleolithic Age have been found in the limestone caves near Creswell, on the Derbyshire border, together with the remains of the mammoth, hyena, cave lion and rhinoceros. Evidence suggests Mesolithic settlements in the north of the county, and more frequent Neolithic and Bronze Age settlements in the open country of the south and east. There are noted Bronze Age settlements at Clifton, and Iron Age sites at Broxtowe. In pre-Roman times there seems to have been a crossing of the Trent, near the site of Nottingham, for the tracks along which salt was carried from Cheshire and Worcestershire. The width of the Trent, with Sherwood forest running immediately on its north, seems to have caused the deflection of the Fosse way northeast-

ward from Leicester toward Lincoln via Newark; thus all the larger Roman sites are on this line, including those at East Stoke, East Bridgford (Margidunum) and Willoughby, while a settlement (Segelocum) at Littleborough shows the Roman penetration from across the Trent westward. The earliest Anglian settlers advanced, not later than the 5th century, either from Lincolnshire along the Fosse way, or from Leicestershire down the Soar valley, and settled in the fertile districts of the south and east. At the end of the struggle between Northumbria and Mercia, the area that later became Nottinghamshire remained as part of Mercia; after the treaty of Wedmore (878), Nottingham became one of the five Danish boroughs. For a short period after the breakup of Mercia the area became annexed to the earldom of the Middle English, but in 1049 it was again included in Leofric's earldom of Mercia. The first mention of the shire of Nottingham occurs in 1016, when it was harried by Canute. The boundaries have remained practically unaltered since the time of the Domesday survey. The growth of the great ecclesiastical "Liberty of Southwell" dates from the period when the archbishop of York was unable to maintain himself in the Scandinavian and heathen north; Southwell minster was founded in the mid-10th century, and the land granted to support the minster was the core of the liberty. At this time, too, Nottinghamshire was transferred from the see of Lichfield to that of York in the province of York, where it remained until 1837, when the archdeaconry was transferred to the see of Lincoln. In 1884, however, a new diocese of Southwell was created, in the province of York, which contained the counties of Nottingham and, until 1927, Derby.

In Domesday Book the fief of William Peverel represents the "Honour of Nottingham" and in 1068 he was appointed constable of the castle which the Conqueror had raised in Nottingham. The chief lay tenant was Roger de Busli, while the archbishop's lands remained undisturbed. The Staunton family probably held land at Staunton at the time of Domesday Book, and other well-known families such as the Pierreponts made their appearance in the county before 1300. Archbishop Cranmer was a descendant of the Cranmers of Aslockton. After the Dissolution several of the monastic houses in the county became the homes of powerful landowners, in an area now familiarly known as the "Dukeries"; Welbeck abbey (since 1953 an army training school) became the seat of the Cavendish family, Rufford abbey that of the Saviles, and Newstead (now owned by the city of Nottingham) that of the Byrons. Further royal grants of land in Sherwood forest included Clumber park, the seat of the dukes of Newcastle (now owned by the National trust), and Thoresby hall, that of the Earls Manvers. Wollaton hall, built for Sir Francis Willoughby in 1580–88 and till 1925 the seat of Lord Middleton, but now owned by the city of Nottingham and containing a natural history museum, is the most spectacular of the great buildings, but only Thoresby hall is still privately occupied, and both Clumber and Rufford have been pulled down. Other great ecclesiastical buildings and ruins include the priories of Thurgarton, Worksop and Blyth. Southwell (*q.v.*) minster, cathedral since 1884, is a magnificent Norman church, with exquisite 13th-century carving in the Chapter house.

Until 1568 Nottinghamshire was normally united with Derbyshire under one sheriff; on the other hand until the 19th century there were two clerks of the peace, one for the shire and one for the extensive secular jurisdiction of the "Liberty of Southwell and Scrooby" which covered the old lands of the archbishop of York, and was paralleled by the ecclesiastical jurisdiction of Southwell chapter and prebends, or the "Peculiar of Southwell."

Among notable historical occasions in the history of Nottinghamshire there may be mentioned the frequent presence of King John in Nottingham or in his manor at Edwinstowe, and his death at Newark. The county was chiefly on the Yorkist side in the Wars of the Roses, and Lancastrian Henry VII defeated the Yorkist pretender Lambert Simnel at Stoke near Newark in 1487. At the beginning of the first Civil War Charles I raised his standard at Nottingham, and at the end surrendered (1646) to the Scots commissioners at Southwell after the prolonged siege of the Royalist-held Newark. Of the old castles the principal remains are those at Newark; there is a fine motte-and-bailey earthwork at Laxton. Laxton is famous as the only village in England that has retained the open-fields system of agriculture. Scrooby was the home of some of the original Pilgrim Fathers.

Population and Administration.—The area of the administrative county, which excludes Nottingham, is 815.1 sq.mi. and its population (1961) was 591,089. The city of Nottingham (pop., 311,899) is a county borough, and there are four municipal boroughs, East Retford (17,792), Mansfield (53,218), Newark-on-Trent (24,651) and Worksop (34,311). There are ten urban and six rural districts. There are six county constituencies, each returning one member to parliament.

The increase in population (by census) from 1901 to 1951 was 92.7%, nearly three times the national increase. The only old towns are Nottingham, Newark-on-Trent, Retford, Southwell, Mansfield and Worksop (*qq.v.*), the remainder being modern residential, industrial or colliery towns.

Shire hall, an 18th-century building by John Gandon, is in the centre of the city of Nottingham but administratively it is in a parish of its own, exclusive of the city. A large new county hall has been built in West Bridgford at Trent bridge facing the famous cricket ground of the Nottinghamshire County Cricket club.

The Economy.—From early times Nottinghamshire has been an industrial as well as an agricultural county. About 73% of the total area is under cultivation. A large part of the county was occupied by Sherwood forest and though most of the old timber had been felled by 1600, the area was still preserved as a royal forest. Reafforestation began in the 18th century and is now carried on by the Forestry commission. Hops used to be grown in the Newark area, and Warsop was a centre for liquorice; but neither are grown there now. The principal crops are barley, wheat, oats, sugar beet, potatoes and grass. There are orchards and market gardens; apple and pear are the principal trees planted, the original Bramley's seedling being raised there. Beet sugar factories are at Colwick and Kelham. Dairy farming (mostly Friesian cattle) occupies most of the heavier land. Sheep have increased in number since 1955 and pigs and poultry are also reared.

The malting and woolen industries flourished in Norman times, and coal and gypsum were mined at an early date. The woolen industry declined in the 16th century, but with the invention of the stocking frame in 1589 by William Lee of Calverton, the hosiery trade was soon established, and Nottingham remains its centre. Many cotton mills were built in the 18th century, together with a few silk mills. The manufacture of tambour lace in the 18th century, greatly increased by the introduction of new machines in the 19th, made Nottingham the world centre for cheap laces, especially curtains, and it still retains this position. Three modern major industries are bicycles, tobacco and pharmaceutical goods, and there is some heavy engineering. The early gypsum mining produced the famous Nottinghamshire alabasters of medieval times, now used for plaster and cement. Nottinghamshire is a principal centre of the gravel industry, there being big deposits in the Trent valley and elsewhere, and clay and sand are also largely extracted. Limestone and sandstone are quarried, and some oil is pumped from wells in the Eakring area. Molding sand is found in the Mansfield area.

The principal mineral extracted has always been coal. First mentioned in 1259, when Queen Eleanor complained of the smoke from the sea coal at Nottingham, the open coal seams in the extreme west of the county began to be developed in the 16th century by men such as Sir Francis Willoughby, whose fortune from coal enabled him to build Wollaton hall at the end of the reign of Elizabeth I. The invention of the steam pump made it possible to extract coal from greater depths, and collieries now extend as far eastward as Boughton, Bilsthorpe, Gedling and Cotgrave. Nottingham is a centre of the garment industry. It has also been for a long time a distribution centre for a large area and the ancient Goose fair still survives, as an amusement fair.

The Midland and Eastern region of British railways serve the county. The river Trent is navigable throughout the county, and the Idle from Bawtry to the Trent. The canal system is largely disused and the small boatbuilding industry at West Stockwith has

completely disappeared since the decline of sailing vessels.

NOUAKCHOTT, capital of the Islamic Republic of Mauritania, west Africa, lies on a plateau near the Atlantic coast, about 270 mi. N.N.W. of Dakar, Senegal. Pop. (1961 est.) 5,510. Although it is in the Sahara, its situation near the sea makes the climate bearable (it has 5 in. of rain during August–October). Before it replaced St. Louis as the capital in 1957, Nouakchott was only a small administrative post with about 400 inhabitants. The new city includes residential districts, an administrative centre, a commercial quarter and a workers' suburb. Between the plateau and the airport is a projected industrial area with power station and slaughterhouses. Water is supplied from wells at Idini. (J. D.)

NOUMENON, a philosophical term put into currency by Kant (*q.v.*) and not much used except in definite reference to his doctrine. In the Kantian system the term "noumena" means things-in-themselves as opposed to "phenomena" or things as they appear to us. According to Kant the human mind is such that it can never penetrate by its speculative powers to things-in-themselves, but can only know phenomena. Thus we have the odd position that noumena, or the contents of the intelligible world, are just the things to which thought can never penetrate. The term, however, is a relic of an early period of Kant's mental development. In his fully mature or critical position he held that the noumenal was inaccessible to the speculative reason, and yet that we are not altogether excluded from it, since the practical reason, *i.e.*, our capacity for acting as moral agents, assures us of the existence of a noumenal world wherein freedom, God and immortality have a real place.

The relation of noumena to phenomena in the Kantian system is a most difficult one; and, in view of the fact that the acutest intellects in Europe have been engaged vainly for more than a century in reconciling the various passages on the subject, the safest conclusion is that they are irreconcilable. The course adopted by Kant's immediate successors in German idealism was to reject the whole conception of noumena, for the reason that what is essentially unknowable has no existence for our intelligence.

Kant, however, protested strongly against this development when it was propounded by Fichte, and held that he had precluded it by his "refutation of idealism": he stood unshakably to the belief in an absolutely real world behind phenomena.

Kant's position may be illogical as he himself stated it, but it is the expression of a sound principle: we must connect it with his general tendency to recognize the dynamic side of things. He saw, what so many of his successors failed to see, that the world as we know it is an expression of power; and he could not imagine whence the power could come if not from a world beyond phenomena. *See* PHENOMENON.

NOVA AND SUPERNOVA. A nova is a variable star that brightens up for a short time to a luminosity far exceeding that of its normal state. A supernova is a nova of great absolute brightness, and is distinguished by a type of spectrum different from that of common novae.

Novae.—Although the initial stages never have been observed, except for recurring novae, the objects subject to nova outbursts are almost certainly stars. The increase in brightness of a star during a nova outburst may be from a hundredfold to a millionfold, and it takes place within a few days. The brightness after maximum may decline at various rates, and it often fluctuates. After a few years, the brightness of the nova remnant usually becomes steady again. Only a few dozen good light curves of novae are recorded.

Some of the novae of greatest apparent brightness are Nova Persei 1901, Nova Aquilae 1918 (almost as bright as Sirius) and Nova Puppis of 1942. Around the remnant stars of these novae gas clouds can still be observed, expanding with velocities of hundreds of kilometres per second. The spectra of these clouds show emission lines of atomic hydrogen, the nebulium lines and λ 3727 of doubly and singly ionized oxygen atoms. The spectral changes from the outburst to the final stages are complex. During the first hours Nova Persei 1901, Nova Herculis 1934 and Nova Lacertae 1936 had continuous spectra with absorption lines, similar to A- and B-type stars. Later on, normal and forbidden emission lines of the elements hydrogen, helium, carbon, nitrogen, calcium, iron, titanium, scandium, chromium, strontium, yttrium and others appear. These lines are widened around their normal places because light comes from shells of gas expanding about the star, the front portions approaching the earth, the rear receding. The dark lines, on the other hand, can originate only in that part of the shell between the earth and the disk of the remnant star that furnishes the background light. Since this part of the shell moves toward the earth, a shift toward the violet results. Spectra of the postnova stars are mostly continuous, with no pronounced absorption lines showing. Even 100 years after a nova outburst, however, faint emission lines are present whose Doppler broadenings indicate that gases steam off the remnant stars with velocities of about 200 km. per second. (*See* DOPPLER EFFECT.)

The absolute magnitudes of novae at maximum brightness can be determined only if the distances are known. There are several methods for estimating the distances, such as from the strength of the "steady" absorption lines due to the presence of interstellar gases along the line of sight to a nova. The most reliable distances are obtained from the observation of the angular diameter of the ejected gas clouds and the comparison of their lateral rates of expansion with the spectroscopically observed radial velocities of these clouds. Thus the absolute magnitudes at maximum of Nova Herculis 1934, Nova Aquilae 1918, Nova Persei 1901 and Nova Puppis 1942 were found to be respectively $M_v = -5.5$, -9.0, -9.2 and -10.0. Common novae therefore reach an absolute visual luminosity in the range from 10,000 to 1,000,000 times that of the sun. The total energy emitted during a large nova outburst in the visual range is of the order of 10^{45} ergs, equal to the radiation from the sun during 10,000 years.

Novae in the Milky Way and in the great nebula in Andromeda (Messier 31) appear most often in the densely populated parts, perhaps at the rate of from 20 to 50 per year. A few common novae have also been discovered in small nearby galaxies, such as NGC 205, the faint elliptical companion of Messier 31.

The spectra of recurrent novae such as T Corona Borealis (1866, 1946) and R. S. Ophiuchi (1898, 1933, 1958) differ materially from those of the bright common novae, and their range in brightness from maximum to minimum amounts to less than nine magnitudes. As to the cause of nova outbursts it has been conjectured that they represent the transition from a normal star into an electronically degenerate star whose density is of the order of 10^6 g. per cubic centimetre.

Supernovae.—These become much brighter than common novae. Pending on the determination of a reliable distance scale for extragalactic nebulae which, in individual cases, is probably uncertain by as much as a factor ten, it seems certain that the brightest supernovae at maximum attain an absolute visual brightness several billion times that of the sun. In any event supernovae often become as bright or brighter than the galaxies in which they appear. For instance, the brightest supernova discovered in the 20th century (in Aug. 1937) was 100 times brighter than the dwarf spiral galaxy (IC 4182), in which it appeared. The total radiation emitted by a bright supernova as visual light during one year is of the order of 10^{50} ergs or more, or equal to the energy radiated by the sun during 1,000,000,000 years.

The light curves of supernovae are varied. Most of those that could be observed sufficiently frequently show a rapid rise during a few days to maximum brightness, near which they may stay for a week or two. The decline in brightness is generally smooth and amounts to 15 or more magnitudes in the course of a few years.

The difference between the brightness at maximum and the final stages is much greater than for common novae.

Most if not all spectra of supernovae have so far defied identification, representing thus one of the most tantalizing puzzles of modern astronomy. Spectroscopic observations reveal at least two types of supernovae. The spectra of bright supernovae, type I, are closely comparable at corresponding times after maximum. They show a bewildering and changing array of wide bands of unknown origin. Some of the fainter supernovae have a type II spectrum that is characterized by a strong ultraviolet continuum and faint emission lines that have been interpreted as atomic hydrogen lines, enormously broadened because of their origin in gas clouds ejected with velocities of 5,000 to 7,000 km. per second. The spectra of supernovae of the type II somewhat resemble those of bright common novae such as that of Nova Sagittarii 1936.

Altogether about 60 supernovae have so far been definitely identified as such. A concerted search by Fritz Zwicky and J. Johnson at Palomar, from 1936 to 1941, netted 19 supernovae. From this search a frequency of one supernova per galaxy per 360 years was derived, if only 1,200 of the brightest galaxies are considered. Supernovae appear in all types of galaxies. In contradistinction to novae, supernovae appear most often in the thinly populated parts of galaxies.

Three supernovae that have made their appearance in the Milky Way system have been definitely identified from historical records. The supernova of 1054 A.D. in Taurus, which was observed by the Chinese to be brighter than Venus, has given rise to a nebulosity, known as the Crab nebula, the gases of which expand with a mean velocity of about 1,100 km. per second. A blue star of the 16th apparent magnitude, with a completely featureless continuous spectrum, may be the very hot dwarf remnant star from the supernova outburst of 1054 A.D. The Crab nebula is also a strong radio source and the continuous visible radiation is polarized giving rise to a most puzzling basket weave pattern when the nebula is subjected to the method of composite analytical photography.

Tycho's Nova of 1572 and Kepler's Nova of 1604 are the other two historically recorded supernovae in the Milky Way. In neither case could a stellar remnant be found, but some expanding wisps of emission nebulosities have been observed in the locations of the two supernovae.

Large ringlike nebulosities such as the famous Cygnus loop are suspected to be remnants of supernovae whose outbursts date more than 10,000 years ago. In the second half of the 20th century radio surveys have led to the discovery of objects like the strong radio source in Cassiopeia, which is associated with diffuse gaseous condensations showing radial velocities of the order of 5,000 km. per second, which indicates that it might be the remnant of a supernova of type II.

No initial stage of any supernova has ever been seen, and it is not certain whether all initial stages are stars. For instance, a large gas and dust cloud, becoming unstable and collapsing, could be the cause of some supernovae. Another likely cause for some supernovae is the collapse of ordinary stars into neutron stars a few kilometres in diameter and with a density of the order of 10,000,000 tons to the cubic centimetre, equal to the density within atomic nuclei.

The further study of supernovae is of importance because they involve a series of new phenomena that promise to clarify views on the evolution of stars, galaxies and the universe in general. Supernovae also bid fair to serve as distance standards for the mapping of the universe to the limits reached with the largest telescopes.

NOVACULITE is a hard, compact, homogeneous, finely granular rock closely resembling chert and consisting of nearly pure silica. The rock has typically a vitreous lustre and white colour. It breaks with conchoidal fracture, and thin edges are translucent. The largest known deposits, Devonian in age, are in the Ouachita mountains of Arkansas and Oklahoma where novaculite occurs as beds from a few inches to ten feet thick, interbedded with shales, forming many of the mountain ridges. It was first quarried in the early 19th century to make whetstones for sharpening fine tools; hence its name, Latin *novacula*, "sharp knife." Indians used novaculite for weapons and implements. Novaculite has been considered to be metamorphosed chert, replacement by silica of a dolomite or limestone, and a deposit of colloidal silica accumulated on the sea floor. (A. W. G.)

NOVAK, VITEZSLAV (1870–1949), Czech composer and teacher. Born at Kamenitz (Kamenice-on-Lipa), then in Bohemia, on Dec. 5, 1870, he studied at the Prague conservatory under Dvorak and in 1909 joined the teaching staff there. His early music was influenced by the romantic school, but after he made a visit to Moravia his music shows a national character. He was also influenced by Debussy and Richard Strauss. His work includes four operas, two ballets and the orchestral works *V Tatrach* ("In the Tatra"), the "Slovakian Suite" and others inspired by Hans Christian Andersen and F. L. Celakovsky. *De Profundis* for orchestra and the "May Symphony" were among his works written during World War II. He also wrote chamber works, songs and many choral works including the "Autumn Symphony." His pupils included many Czech composers of the following generation. He died at Skutec on July 18, 1949. (J. S. Wn.)

NOVALIS, the pseudonym of Georg Friedrich Philipp, Freiherr von Hardenberg (1772–1801), German poet and important early Romantic theorist, was born on May 2, 1772, on his father's estate of Oberwiederstedt in Prussian Saxony. His family, which belonged to the Protestant Lower Saxon nobility, had also called themselves de Novali in the 13th century. After completing his schooling he began to study law, first at Jena (1790), then in Leipzig. Meetings with Schiller, his friendship with F. von Schlegel and his introduction to the critical philosophy of Kant and Fichte's *Wissenschaftslehre* were landmarks in these years. He read philosophy and history as well as law and after finishing his studies in 1793, at Wittenberg, he used his period of training in local government to enlarge his knowledge further, particularly in natural sciences. In 1795 he became engaged to the 14-year-old Sophie von Kühn. Her death in 1797 turned him into a citizen of two worlds, life and death. Six *Hymnen an die Nacht* (1800; Eng. trans., *Hymns to the Night*, 1948 and 1960), prose poems interspersed with verse, celebrate death as entry into a higher life in the presence of God. In 1797 he went to Freiberg to study mining and in 1800 took an administrative post in the Saxon salt works. In 1798 he had again become engaged, to Julie von Charpentier, but died of tuberculosis on March 25, 1801, at Weissenfels, before he could marry. His last years were astonishingly creative, filled with encyclopaedic studies and with the draft of a philosophical system based on Idealism. A giant collection of fragments—even now not fully exhausted—was to be the basis of a "scientific Bible." His real poetic work also belongs to this period.

Two collections of fragments which appeared during his lifetime, *Blütenstaub* (1798) and *Glauben und Liebe* (1798), indicate the range of his mind, which attempted to unite poetry, philosophy and science in an allegorical interpretation of the world. He wrote two novels, both fragments, the natural philosophical *Die Lehrlinge zu Sais* (1798; Eng. trans., *The Novices of Sais*, 1949) and *Heinrich von Ofterdingen* (1799–1800; Eng. trans., 1842), his most important work. Like his Romantic friends, Novalis believed that Heinrich von Ofterdingen (a *Minnesinger* who only survives as a name) was the author of the *Nibelungenlied*. Set in an idealized vision of the middle ages, the book's theme is the mission of the poet to transform the world into the poetry of fairy tale through the magic power of the imagination, symbolized by the blue flower for which the hero searches. The essay *Die Christenheit oder Europa* (1799) depicts the history of Christianity as the threefold process of unity, disintegration and new unity. A universal Christian church was to restore, in a new middle ages, a Europe which had been split by Reformation and Enlightenment. Appearing only after Novalis' death, the essay was long understood as establishing the trend of the Romantic generation toward the Roman Catholic Church.

Novalis' influence on the later Romantics and on symbolism in

Germany, France and England was considerable, although it was his *Geistliche Lieder* (1799; Eng. trans., *Sacred Songs*, 1956) which had the most direct effect. Encouraged by F. D. E. Schleiermacher (*q.v.*), he meant these to be hymns for the new church he envisaged.

NOVA LISBOA, a town of Angola, southwest Africa, chief town of the district of Huambo. Pop. (1960) 70,629, including 53,526 Africans, 12,510 Europeans and 4,589 mixed. Nova Lisboa, founded in 1912 and originally intended to become the capital of Angola, lies in the heart of the country, 300 mi. S.E. of Luanda, at an altitude of 5,580 ft., and enjoys a climate suitable for European settlement. It is an important centre of the road network, internal airlines and the Benguela railway. Its railway repair shops are the largest in Africa. The town has a considerable industrial and commercial activity—shipping maize, wheat, rice, fruit, hides and skins—and an active cultural life. It was called Huambo till 1928. (A. A. G. P.)

NOVARA, a town of northwest Italy, region of Piedmont, capital of the province of the same name, lies on the Agogna river, 29 mi. (47 km.) W. of Milan by road. Pop. (1961) 90,699. The town is situated on a low, flat ridge above the surrounding plain of the Po. The cathedral was rebuilt 1863–65 except for the 10th-century octagonal domed baptistery and the 11th-century campanile. The basilica of S. Gaudenzio was built 1577–1659, and the town hall dates from the 13th century. The 15th-century palazzo del Podestà (mayor's palace) stands beside an 18th-century loggia. The 12th-century castle is used as a prison. Other features are a museum of antiquities, the Istituto Geografico di Agostini and the much-restored Broletto, an assemblage of buildings of various dates. Novara is on the main railway from Milan to Turin; other lines run to Genoa, Bergamo and the shores of Lake Maggiore. It is at the intersection of national highways. The most important industry is the production of various kinds of cheese, especially Gorgonzola. Minerals, chemicals (especially gas), metals, textiles, glass, ceramics, electrical equipment and clothing are also produced. Novara is an important sport and tourist centre.

Known as Novaria to the Romans, the town has a rectangular plan probably surviving from those days. After a long period of independence it accepted the protection of Milan in the 12th century. In 1706 it passed to Savoy and was ruled in turn by Austria, Savoy, France (when it was the capital of Agogna *département*) and again Savoy. The scene of Austrian victories in 1821 and 1849, it became part of the kingdom of Italy in 1861.

NOVARA PROVINCE stretches from the Pennine Alps and the Swiss frontier to the flat Po valley. Lake Maggiore forms part of its eastern boundary. The Simplon tunnel is partly in the province. Chief towns are Domodossola, the resorts of Intra and Stresa, Arona, Borgomanero, Omegna, Galliate and Trecate.

NOVA SCOTIA, a province on the east coast of Canada, composed of the peninsula of Nova Scotia and the adjoining island of Cape Breton. The extreme length from southwest to northeast is 371 mi. (Nova Scotia 266, Cape Breton 105); breadth 59 to 75 mi.; area 21,425 sq.mi. The isthmus of Chignecto, 17 mi. wide, connects it with the province of New Brunswick. The capital of Nova Scotia is Halifax (pop. [1961] 92,511; metropolitan Halifax, 183,946).

PHYSICAL GEOGRAPHY

Geology and Physiography.—Nova Scotia is composed of five upland and as many lowland areas. The former are underlain by hard crystalline rocks and comprise: (1) the Southern upland, which embraces the southern half of the peninsula and rises gradually from the coast to elevations of 600 ft.; (2) North mountain, a narrow, flat-topped belt (590 ft. high) extending for 120 mi. along the Bay of Fundy shore from Cape Blomidon to Brier Island; (3) the Cobequid mountains (average elevation 840 ft.) stretching for 71 mi. across Cumberland county from the head of the Bay of Fundy almost to Northumberland strait; (4) the highlands of eastern Pictou and Antigonish counties (elevation 800 to 900 ft.); (5) the upland belts and northern tableland (Cape Breton highlands, elevation 1,200 ft.) of Cape Breton Island.

The lowland areas are underlain by softer sedimentary rocks. The three more important are the Annapolis valley, a long trough-like depression lying between the steep walls of North mountain and the Southern upland; the lowlands surrounding Minas basin; and the lowland between the Cobequid mountains and Northumberland strait.

Nova Scotia has a myriad of lakes, short rivers and streams. The salt water Bras d'Or lake (*q.v.*) of Cape Breton Island is particularly large and well known. The Bay of Fundy tides exceed 50 ft. in Minas and Cumberland basins, resulting in large areas of tidal marshlands.

Climate.—The climate of Nova Scotia is under both continental and oceanic influences, especially along the southwest coast which is both milder and wetter than other parts of the province. The average annual temperature is 45° F. along this coast, but only 40° in the interior uplands where temperature extremes of 95° in summer and −35° in winter have been recorded. Similarly, the frost-free season varies from 100 days or less in the uplands to 140 days along the south shore, Northumberland strait and in the Annapolis valley, and to 160 days in the Yarmouth area. Rainfall is normally ample and well distributed throughout the year—an annual average of 55 in. on the south coast; 40 in. elsewhere in the province. Less than one-fourth falls as snow; fog occurs on as many as 90 days along the southern shore.

Vegetation.—Slightly more than 15,000 sq.mi. (70% of the province) is forested. Softwood stands account for 55% and hardwood stands for 6%, while the remainder is mixed. Balsam fir, spruce (red, white and black), eastern hemlock and white pine are the principal softwood species while yellow birch, sugar maple and red maple are the main hardwood types. With the widespread abandonment of agricultural land from 1900 the forested area has been continually expanding.

Nova Scotia has approximately 50,000 ac. of tidal marshland around Annapolis, Minas and Cumberland basins and along Northumberland strait. Dikes were begun by the Acadians in the early 1700s and the marshes are now largely in agricultural use.

Animal Life.—Nova Scotia has an abundance of wildlife which attracts many sportsmen to the province. Moose and especially deer are common. In addition there are many fur-bearing animals, including the bear, raccoon, beaver, muskrat, woodchuck, rabbit and red squirrel. Of the many species of birds, partridge (grouse) and ducks are most popular as game. Speckled trout and Atlantic salmon are the most valued fresh-water fish.

HISTORY

Nova Scotia may well have been the Markland of early Norse and Icelandic voyages, and Cape Breton was visited by the Cabots in 1497–98, but not until 1605 was any attempt at permanent colonization made by Europeans. In that year, Pierre du Guast sieur de Monts (1560–c. 1630) and Samuel de Champlain (1567–1635) after an unsuccessful attempt on an island in Passamaquoddy bay, founded the first settlement north of Florida on the north shore of Annapolis basin. The habitation was destroyed by English colonists from Virginia in 1613. In 1621 Sir William Alexander obtained a grant to the whole peninsula from James I and named it Nova Scotia (Latin for "New Scotland"), replacing the French name Acadie, à descriptive word of the Micmac Indians. Two settlements were established but with the restoration of Nova Scotia to the French by the treaty of St. Germain-en-Laye in 1632 most of the Scottish settlers returned home. French and British control of the peninsula alternated until the treaty of Utrecht (1713) when it passed into the possession of Great Britain. France retained the present areas of Cape Breton, Prince Edward Island and New Brunswick, and constructed the mighty fortress

of Louisburg on Cape Breton Island. In 1749 Halifax was founded as a counterpoise to Louisburg, and more than 4,000 British colonists were sent out. Moreover, the British attempted to exact allegiance from the French Acadian population. In 1755, fearing that the Acadians could not be neutral in the case of war, Gov. Charles Lawrence decided that they must either take the oath of allegiance or be deported. With their refusal there followed the tragic expulsion (made famous in Longfellow's *Evangeline*) in which approximately 6,000 Acadians were forced to leave the colony. After France lost its North American colonies in 1763, many returned to Nova Scotia, took the oath of allegiance and obtained new lands. (*See* ACADIAN.)

Soon after the Acadian expulsion, promises of free lands lured settlers from New England, Yorkshire, Ireland and Scotland. In 1758, in deference to the New Englanders in Halifax, the first popular assembly was elected. Cape Breton and Prince Edward Islands became parts of Nova Scotia in 1763, although Prince Edward Island was detached six years later and has remained a separate province ever since.

At the beginning of the American Revolution about one-half of the settlers in Nova Scotia were of New England origin but they did not share all the grievances of the southern colonists. The province strove to retain its neutrality through the struggle, although four delegates from Cumberland went to the continental congress in Philadelphia. At the close of the war about 35,000 Loyalists flocked to Nova Scotia and, as a result, New Brunswick and Cape Breton became separate colonies in 1784. Cape Breton was reunited with Nova Scotia in 1820.

In the first half of the 19th century a substantial increase in population (Scottish, Irish, Negroes) occurred along with new wealth and increased trade. The timber trade and fisheries boomed, and Nova Scotia shipbuilding enormously expanded. The colony had 2,583 vessels in 1846, representing one-third as much tonnage as that of France. However, political life lagged behind because of the peculiar privileges of a small official class. The struggle for responsible government, which marked the 1830s and 1840s, finally met with success in 1848 when Nova Scotia became the first British colony to have the principle of responsible government recognized.

Nova Scotia prospered greatly between 1855 and confederation as a result of improved British trade, the reciprocity treaty (1854) with the United States, and the American Civil War. The province bitterly opposed a union with Upper and Lower Canada, but the dynamic leadership of Charles Tupper (*q.v.*) led the province into confederation in 1867 (with New Brunswick, Ontario and Quebec). The case of the opposition was carried to London by the great orator and journalist, Joseph Howe (*q.v.*), but finally even he accepted a state of federated provinces.

Nova Scotia has had a sense of grievance ever since confederation and one political election (1886) was even won on the platform of secession. Several adverse factors including abrogation of the reciprocity treaty in 1866, the cessation of the American Civil War, the opening of the Canadian west and the changes in shipbuilding from wood and sail to steel and steam retarded the economy. Politics in the 20th century have largely turned on the province's economic status in spite of improvements effected by the steel and coal industries, by local manufactures, and by the development of Halifax, along with Saint John, N.B., as Canadian winter ports. In 1926 and 1934 royal commissions investigated the economic problems and reported in favour of better terms for the province. World War I stimulated the provincial economy along many lines but the depression that followed was not checked until the late 1920s. Another boom occurred during and after World War II and in the early 1960s economic progress continued to be favourable, net value of production having doubled since the war.

The province has had several disasters of international concern. Springhill has been the scene of three coal-mine explosions, one occurring in 1958 when 75 men were killed or died as the result of a "bump." The collision of two steamships, one carrying TNT, explosive acid and benzine, in Halifax harbour in 1917 resulted in the death of nearly 2,000 people.

There are seven national parks in Nova Scotia, six of which are national historic parks. Cape Breton Highlands National park is located in the northern part of the island and has equipped recreational and camping grounds. The Fortress of Louisburg National Historic park is also on the island, located at the site of the ruins of the French fort built between 1717 and 1758. An exact replica of the habitation built by Champlain has been erected at Port Royal. Fort Anne National Historic park commemorates early French settlement and a British fort at the present site of Annapolis Royal. Grand Pré National Historic park is located near Wolfville and preserves a site of early Acadian history made famous by Longfellow's *Evangeline*.

The Citadel at Halifax is also a national historic park. In addition there are numerous historic sites, plaques and cairns in all parts of the province.

POPULATION

The population of Nova Scotia was 737,007 in 1961, with slightly over one-half living in the rural areas. Almost two-fifths of the population was in the urban areas of Halifax and Sydney. More than 75% were of Anglo-Saxon origin while 11% were Acadian French. The latter live mainly in Digby, Yarmouth, Shelburne and Richmond counties.

There are 18 counties in the province.

*Nova Scotia: Places of 5,000 or More Population**

*Populations are reported as constituted at date of each census.

GOVERNMENT AND PUBLIC FINANCE

The administration of Nova Scotia consists of a lieutenant governor appointed and paid by the federal government, and by custom a resident of the province; a premier and cabinet representing the party in power; federally appointed judges; and a nonpolitical civil service. The legislative assembly of 43 members meets at Halifax; elections may be called any time within a five-year period. Nova Scotia is represented in the federal government in Ottawa by 10 senators (from 1873). Membership in the house of commons is adjusted after each census; it was 12 after the 1956 census.

There are 2 incorporated cities, Halifax and Sydney (*qq.v.*) and 40 incorporated towns. In addition there are 24 municipalities, of which 12 are county municipalities and 12 are district municipalities representing 6 divided counties.

Under the terms of confederation the province is concerned with the protection of persons and property, transportation and communications in local undertakings, natural resources, education, health and welfare, and the incorporation of companies. The sources of revenue collected for provincial purposes are various and are augmented by federal government subsidies and grants as well as various tax-sharing agreements.

EDUCATION

Public education dates from 1811 and is compulsory, free of charge and nondenominational. In the second half of the 20th century there were approximately 2,000 schools, with about 125,000 attending elementary classes and 20,000 in secondary schools. There were approximately 5,000 attending classes in private schools and another 8,000–9,000 receiving precollege training in various other classes. The major institutions of higher learning are Dalhousie university, Halifax; University of St. Francis

Xavier, Antigonish; and Acadia university, Wolfville. Others are College Ste. Anne, Church Point; Convent of the Sacred Heart, Halifax; University of King's college, Halifax; Pine Hill Divinity hall, Halifax; Mount St. Vincent college, Halifax; Nova Scotia Agricultural college, Truro; Nova Scotia Technical college, Halifax; Holy Heart seminary, Halifax; Maritime School of Social Work, Halifax; and St. Mary's university, Halifax. The Nova Scotia Teachers' college (formerly the provincial normal school) at Truro was established in new quarters in 1961 and a new two-year teacher-training program was introduced.

MAJOR PHYSICAL FEATURES AND INDUSTRIAL AREAS OF NOVA SCOTIA

PRODUCTION

Agriculture.—Nova Scotia has very little agricultural land (under 5% of the total area). Aside from the Annapolis valley, the marshlands around Minas and Cumberland basins, and areas along the Northumberland strait shore, most of the province is too rugged, or has soils which are too thin and infertile to support the industry. Mixed farming (often part-time) is the rule with an emphasis on dairying in proximity to the larger urban centres. Over one-half of the cropland is in hay, with a large additional acreage in pasture. The Annapolis valley is well known as an apple-growing region, although production has declined because of the curtailment of the British market after World War II. Small fruits and vegetables are also grown commercially in that area. There is a livestock specialization in association with the marshlands and an increased egg and poultry production encouraged by the Bermuda market. Blueberry production has also increased greatly after World War II.

Forestry.—Lumbering was long the chief industry of Nova Scotia and, although the timber resources account for little more than 2% of the Canadian total, it is still a major source of provincial income. Most of the forests are privately owned and this, together with the dependence of the industry on a great many small waterways, has resulted in many scattered, small-scale lumber operations. A few large-scale operations, notably the pulp and paper mills at Liverpool (Brooklyn), New Germany, Hantsport, Point Tupper and Sheet Harbour, have developed along the larger river systems.

Mining.—Coal is the most important Nova Scotia mineral. The principal mining centres have been Glace bay, New Waterford, Sydney mines, and Inverness on Cape Breton Island; Stellarton and Westville in Pictou county; and until 1958, Springhill in Cumberland county. Several additional coal mines have been permanently closed. There are iron ore reserves in the Nictaux-Torbrook area but the ore for the blast furnaces at Sydney is imported from Newfoundland. Gold production reached a peak in 1939 (29,943 oz.), but had declined to negligible amounts by the second half of the 20th century. Large deposits of gypsum occur at Windsor, Milford station, Walton, Little Narrows and Dingwall. The province is the principal Canadian source of barite and a major salt producer.

Fisheries.—Fish has long been one of the important exports of the province. Dried cod, the traditional export item, is still important although fresh frozen fish has increased in value from 1945. Three-fifths of the value is obtained from the deep-sea fisheries, chiefly from cod and haddock; one-quarter from mollusks and crustaceans, particularly lobsters; and the remainder from the surface fisheries and other products. Digby and Wedgeport are noted for scallops and tuna respectively.

Industries.—Nova Scotia is naturally a sea-going province, and ship construction and fish packing and processing have always been major industries. Large supplies of raw materials (coal, limestone, iron from Newfoundland) have favoured Sydney as a primary steel centre. Other steel mills are located at New Glasgow, Trenton and Amherst. Iron and steel products and transportation equipment represent nearly one-third of the selling value of factory shipments, foods and beverages account for about one-fourth and pulp, paper and wood products for one-eighth, with the remainder divided among textiles, clothing, nonmetallic minerals, chemical products, printing and publishing and miscellaneous industries. The principal manufacturing centres are Halifax, Sydney, New Glasgow, Trenton, Pictou, Amherst, Dartmouth, Yarmouth, Truro, Lunenburg, Shelburne, Bridgewater, Louisburg, Windsor, Kentville, Hantsport and Berwick.

COMMUNICATIONS

The major railways of Nova Scotia are the Canadian National and Dominion Atlantic. The Canadian National enters the province near Amherst (from Montreal and Moncton) and has main lines leading to Halifax and Sydney and branch lines to Yarmouth and the Annapolis valley. The Dominion Atlantic, a subsidiary of the Canadian Pacific system, connects with Saint John, N.B., via ferry to Digby and serves Yarmouth, Halifax and Truro. Airports are located at Eastern passage, Kelly lake (both serving Halifax), Yarmouth, Trenton and Sydney. The province has had an impressive highway grading and paving program; out of a total road mileage of about 15,000, more than 2,000 mi. were paved by 1960. A deep causeway (218 ft.) connecting the mainland with Cape Breton Island was opened in 1955.

Ferry service operates between Yarmouth and Bar Harbor, Me.; Digby and Saint John, N.B.; and Caribou and Prince Edward Island.

NOVATIAN (NOVATIANUS) (*c.* 200–*c.* 258), Roman theologian and one of the earliest antipopes, who gave his name to the Novatian schism. He was ordained at Rome and about 250 he occupied a leading position among the Roman clergy. In their name he wrote two letters to Cyprian, with whom he at that time stood

in his moderate attitude toward the Christians who apostatized during persecution. Later, when Cornelius became bishop of Rome (251), Novatian appointed himself as rival bishop and a champion of rigorism. He and his followers were excommunicated. The Novatian schism developed into a rigorist sect which spread all over the empire and lasted for several centuries. The assertion of the church historian Socrates that Novatian was martyred under Valerian seems to be confirmed by an inscription with the words *Novatiano . . . martyri,* found in 1932 in a cemetery near San Lorenzo in Rome.

Novatian was the first Roman theologian to write in Latin. His most important work, the *De trinitate,* sums up the orthodox doctrine of the Trinity. In *De cibis Judaicis* he points out that the food laws and other practical prescriptions of the Old Testament must be understood spiritually henceforth. In *De spectaculis* he condemns attendance at public games. *De bono pudicitiae,* on chastity, depends on Tertullian and Cyprian.

Hartel among works of Cyprian, *Corpus scriptorum ecclesiasticorum Latinorum,* vol. iii (1868–71); *De trinitate,* ed. by W. Yorke Fausset (1909); *De cibis,* ed. by G. Landgraf and C. Weyman, *Archiv für lateinische Lexikographie,* 11:221–249 (1900). Eng. trans. in *Ante-Nicene Fathers,* vol. 13 (1869). For further bibliography *see* J. Quasten, *Patrology,* vol. ii, pp. 212–233 (1953). (CH. MO.)

NOVAYA ZEMLYA is an arctic archipelago off the coast of the Russian Soviet Federated Socialist Republic, U.S.S.R. Administered as part of Archangel *oblast,* it consists of two large islands separated by a narrow winding channel 56 mi. long, the Matochkin Shar (strait), and many small islands. It lies between latitude 70° 26′ and 77° N., and between longitude 51° 26′ and 69° 12′ E. and forms an elongated crescent, being more than 600 mi. long, with a width of 25 to 68 mi. and an area of about 31,382 sq.mi. It separates the Barents sea on the west from Kara sea on the east. With Vaigach Island 30 mi. to the south, and the mainland, Novaya Zemlya ("new land") forms a continuation of the Khrebet Pai-Khoi, a branch of the Ural folds.

The greatest heights occur near Matochkin Shar (about 3,500 ft.). Ice covers about a quarter of the total area, lying mostly in the north island.

A central zone of upper Cambrian and Devonian rocks extends along the islands. These quartzites, conglomerates and dolomites are flanked by carboniferous shales and limestones. Copper and other metallic ores are known. The coast is severely indented and has raised beaches which give good landing places.

Novaya Zemlya is colder than Spitsbergen (which lies more to the north) as in some degree it shares in the continental conditions of northern Russia and Siberia. The middle and northern parts of the west coast are not so cold as the east. Temperatures at Karmakuly on the west coast (the warmest part) are −17° C. (2° F.) in February and 6° C. (43° F.) in July. Snow is universal from October to May.

Vegetation is solely tundra and decreases from south to north. It is most luxuriant in the southwest. There are few trees or bushes. The flowering plants number about 200.

In the ice-free areas there are foxes, lemmings, bears and reindeer. Insects are numerous near the coast. Countless birds come from the south for the breeding season, and at certain parts of the seacoast the rocks are covered with millions of guillemots, while great flocks of ducks of various sorts, geese and swans swarm every summer on the valleys and lakes of the south. Whales, walruses and various seals are frequently seen. The arctic char and some salmonate species occur in the rivers, and cod frequent offshore waters.

The abundance of sea mammals and birds attracted Russian hunters, and even in the 16th century they had extended their huts to the extreme north of the island. Many of them wintered for years on Novaya Zemlya. Because of the ice in the White sea, Russian hunters found Novaya Zemlya less easy of access than did the Norwegians. But about 1877 systematic attempts at settlement were begun by the Russian government, several families of Samoyeds (Nenets or Nentsy) being established at stations on the west coast of the south island, including Malye Karmakuly on Moller bay, Pomorka bay and Belushya bay.

History.—Novaya Zemlya was probably known to Novgorod hunters in the 13th century and to Norse hunters earlier still. In 1556 Stephen Borough reached the south extremity of Novaya Zemlya, being the first western European to do so. Willem Barents touched the island (1594) at Sukhoi Nos (latitude 73° 46′) and followed the coast north to the Orange Islands (Ostrova Oranskiye) and south to the Kostin Shar. In 1596, after his discovery of Spitsbergen, Barents wintered at Ice Haven in 76° 12′ N. In 1760 Savva Loshkin cruised along the east coast, spent two winters there, and in the next year returned along the west coast, thus accomplishing the first circumnavigation; but the records of his voyage have been lost. In 1768 Lieut. F. F. Rozmyslov explored Matochkin Shar, where he spent the winter. The first scientific information about the island is attributable to the expeditions (1821–24) of F. P. Litke (Lütke; 1797–1882). Nearly all the west coast as far as Cape Nassau, as well as Matochkin Shar, was mapped and valuable scientific information obtained. In 1832 and 1835 Lieut. P. K. Pakhtusov mapped the east coast as far as 74° 24′. Karl Ernst von Baer made further investigations in 1837, and A. K. Tsivolka in 1838–39. Expeditions have become less dramatic and more numerous since the middle of the 19th century, particularly since 1920. A weather station has functioned at Karmakaly since 1896; to this was added an observatory at Matochkin Shar (1923), and further weather stations at Cape Zhelaniya (1931), Russkaya Gavan (1932), Capes Stolbovoi and Vykhodnoi (1934), and Cape Menshikova (1953). The settlements (pop. about 400) in the south island continue to exist, maintained by trapping, raising reindeer and collecting eiderdown.

(T. E. A.)

NOVEL. "A fictitious prose narrative or tale of considerable length (now usually one long enough to fill one or more volumes), in which characters and actions representative of the real life of past or present times are portrayed in a plot of more or less complexity"—so the *Oxford English Dictionary.*

There are obviously many difficulties about this (or any other) definition of the novel, and they have led some critics to deny that there really is such a thing as the novel form, or to assert that it is too vast, various and amorphous to be considered a literary kind or genre. It is certainly true that the novel, beginning much later than the other main literary kinds, never established a definite formal tradition based on its first recognized models of excellence, as the epic, for example, did with Homer's *Iliad.* But we obviously need a term to describe the mode of writing which has been the most characteristic literary phenomenon since the mid-18th century; usage has established the term novel; and a brief consideration of the problems raised by the various items in the definition above may clarify our understanding of the kind of narrative it denotes.

GENERAL DESCRIPTION

First, the problem of "fictitious." The novel is essentially a fictitious literary form; and yet its subjects are often taken from actual events, and its narrative methods typically attempt to create an air of literal truth. This dualism exactly reverses that of the epic, which had a sort of nonfictional, if not wholly historical, status, although its subjects were legendary and its narrative methods laid little emphasis on literal authenticity. The contrast is historically revealing: the novel arose in a much later civilization, and one whose outlook paid great attention to the distinction between fact and fiction. The novelist typically claims for his fictions the authority of fact; and many early novels imitated the letter and the memoir, modes of writing used to relate actual happenings.

The novel's being in prose follows from these considerations. For just as the content of earlier narrative is largely historical or legendary, its mode is usually poetic; similarly the novel's pretense at literal authenticity seems to demand prose, the medium of common speech. This requirement in turn leads to another larger historical contrast: mankind's early modes of literary expression were public, and public recitation or song apparently seemed to require the impressiveness and memorability of

formally patterned and ornamented speech; prose literature came later, and the novel is the only major literary form which was not shaped under conditions of public and oral delivery.

The "considerable length" of the novel raises difficult problems. Dramatic performance, or indeed any public occasion, tends to set up fairly standard expectations of length. Not so with the novel, nor indeed with any form intended mainly for private reading. The scale of novels varies widely, from the 2,000,000 or so words of Marcel Proust's *À la recherche du temps perdu* to the 250-page norm common today—roughly E. M. Forster's minimal specification of "over 50,000 words" (*Aspects of the Novel*, 1927). Below this lower limit, there are two other recognized forms of prose fiction: the short story, for anything up to about 50 pages; and the longer category intermediate between the short story and the novel, for which, English having no better term than the clumsy "long short-story" or the somewhat derogatory-sounding novelette, the French word *nouvelle* is often used. It must, however, be remembered that the Italian term *novella* and the German *novelle* are also applied to what we would call short stories.

The definition's stipulation that the novel portrays "characters and actions representative of the real life of past or present times" brings us to the heart of the problem. People have been quarreling about "reality" ever since the world began; and obviously any definition which arrogates all portrayal of "real life" exclusively to the novel, and which completely denies it to other literary forms, is hopelessly narrow and provincial. The character and actions of Homer's Odysseus have just as much reality in their way as those of Fielding's Tom Jones; the question of the meaning of "real" in such a context obviously needs further definition, to make clear that the novel's defining "reality" is a more mundane and literal one than that of the epic. Characters in a novel, if not statistically average, are at least not normally so far outside the usual dimensions of common life as to be patently of the heroic stuff of history or legend; and their actions are usually both more usual in themselves, and more deeply rooted in common life by a minuter description of the environment than is typical of other kinds of narrative. This steady attention to the surface of things—houses, goods, appearances, daily life, ordinary conversations—is typical of the novel's technique; but one must remember that although it can lead to the supreme truthfulness of a Tolstoi, what may be called the novel's realism of presentation does not ensure realism of assessment; convincing accuracy of surface description can mask an essential lack of understanding or judgment about the actual conditions and values of life.

According to the definition the novel may portray actions and characters "of past or present times." But—in this again unlike earlier kinds of narrative—it is more typically concerned with the contemporary. The word novel itself is ultimately derived from the Latin *novus*, meaning "new," via the Italian word for a short story, *novella*, which tended to mean not only "an original as opposed to a traditional" story, but also one that was, pretendedly at least, "of recent occurrence." When the word was adopted in English it kept some of this duality; novel could mean "news" as well as "a short prose fiction" until the 18th century, when its present meaning finally became established. Something of this connotation remains; fiction dealing with times long past, the historical novel, has a special name, and is surely felt to be rather a special case, probably because we cannot be so sure of the reality of things which neither we nor the author have directly experienced.

The last phrase of the *Oxford Dictionary's* definition, "in a plot of more or less complexity," raises an important though rather intangible problem, and one which helps to distinguish the novel from the prose fiction of other times and places. The word plot itself immediately involves a considerably higher level of narrative organization than normally occurs in a story or a fable. To quote E. M. Forster's formulation, a story is merely "a narrative of events arranged in their time-sequence," whereas a plot organizes the events according to a "sense of causality." This causal linkage of all the actions and characters is obviously very difficult to achieve in a narrative of novel length; it requires, therefore, the unity in variety denoted by the word complex; and historically, the novel developed as soon as causal narrative structures with sufficient scale and complexity were created. Such structures, in turn, depended on a set of basic assumptions which seem to be peculiar to modern western society. Since Aristotle western civilization has been permeated by the idea of causality; and this cause and effect thinking has taken an increasingly secular and individualist direction. It has therefore become natural to envisage a plot in which human life is seen as exclusively determined by the cumulative effects of individual actions. Only with such a plot could one get the kind of novel which led Henry James to ask: "What is character but the determination of incident? What is incident but the illustration of character?" Such plots are not found even in the supreme masterpieces of China and Japan, which went further than any other nonwestern country in the development of large-scale prose fiction. *The Dream of the Red Chamber* (18th century) and *The Tale of Genji* (11th century), for example, are wholly convincing in background and very sophisticated in psychology, but their plots are not controlled by the sense of the reciprocal causality of character and action on which the coherent unfolding of the masterpieces of the western novel ultimately depends.

CLASSIFICATION OF NOVELS

One possible classification of novels is based on a similarity to some other mode of writing. Beginning with Defoe, who presented his fictions in the guise of historical, travel, religious or criminal memoirs, the novel has taken over the techniques of many other literary kinds. Less specifically, the more defined and stylized ways of looking at life which are the basis of some of the other literary genres find their spiritual, and to some extent their formal, parallels in certain kinds of novel: Jane Austen's novels are very close to the comedy of manners, while Thomas Hardy's *The Return of the Native* has many of the characteristics of tragedy.

Of even greater critical importance is the tendency of novels to group themselves together according to their own intrinsic similarities to each other in manner and matter: a novel's plot, structure and style are inevitably affected by such elements as its setting in place and time, the kind of character it portrays and the role allotted him, and the nature of the author's larger intentions.

Structural Categories.—Percy Lubbock in *The Craft of Fiction* (1921) and Edwin Muir in *The Structure of the Novel* (1929) suggested certain fairly similar basic structural categories. In the "dramatic" or "scenic" novel such as Henry James's *The Ambassadors*, the narrative mainly proceeds in a fairly small number of important scenes which are presented rather completely, as in a play; and this concentrated focus necessarily involves a restriction of the time and space dimensions. At the other extreme is the "panoramic" novel, such as Thackeray's *Vanity Fair*, where the point of view of the novelist ranges over rather wide expanses of time and space; here the narrative is more like a running commentary than a play. Sometimes, as in Tolstoi's *War and Peace*, the narrative ranges equally widely in space and time, but there is more often a greater emphasis on one or the other. Where the essential emphasis is spatial, we have the adventure novel, such as Stevenson's *Treasure Island*, or the picaresque novel, such as Smollett's *Roderick Random*: we are very conscious in both of the wide variety of places to which the action takes us. In another and more recent kind of novel, we are much more aware of the temporal dimension, of the flow of time; such works as Arnold Bennett's *The Old Wives' Tale* or John Galsworthy's *Forsyte Saga* belong to this category, and may be called chronicle novels.

The time setting in another sense provides the basis for a different kind of classification: the historical or period novel. It has at least three fairly distinct kinds. In one, where actual historical persons and actions are the basis of the novel, the work is really fictionalized history: Robert Graves's brilliant Roman reconstructions such as *I, Claudius* for example. At the opposite extreme is the historical romance or period novel in which the past is used merely as an exciting and exotic background for adventures—quasi-military in Dumas' *The Three Musketeers*, sentimental in Margaret Mitchell's *Gone With the Wind*. Between the

two extremes of antiquarianism and romantic fantasy is the historical novel proper, where there is an authentic historical background but where the chief characters and actions are fictional: Sir Walter Scott's novels are the classic models of the genre, and his example suggests that the success of the historical novel tends to be proportional to its closeness to the author's own time: *Waverley, or 'Tis Sixty Years Since* (1814) dealt with times that were just within living memory.

The particular setting of a novel in place affords an even greater variety of classification according to content. The spatial equivalent of the historical romance is the exotic novel, where the background is treated in a spirit not of topographical accuracy but of romantic escape. The regional novel as a serious genre has been developed in many directions since Maria Edgeworth's studies of Irish provincial life and Balzac's category of "Scenes of Provincial Life" in *La Comédie Humaine*. There are, for example, the American novels of the south, and the many great fictional studies of rural, urban and metropolitan communities—George Eliot's *Middlemarch*, Sinclair Lewis' *Main Street* and Balzac's *Le Père Goriot*, for example.

Kinds of Characters.—The kind of character in a novel and the role allotted him provides the basis of several important fictional traditions, which may or may not coincide with classifications based on the treatment of time and place. The oldest, and perhaps the commonest, kind of novel is that which bases whatever narrative unity it possesses on the dominance of a single character. Where the character is, in Aristotle's phrase, "less good than ourselves," we have the picaresque novel. The term is often employed as if it were the equivalent of "highly spiced" in cooking, but its derivation—from *picaro*, Spanish for "a rogue"—indicates that it strictly applies only to novels where the chief character, like Thomas Mann's Felix Krull, is a conspicuous dissenter from established moral and social codes. Where there is one chief character, neither a hero nor a villain but somewhere within the ordinary moral range, we get the ordinary biographical novel which is perhaps the largest of all classes. It, in turn, has many different species. Formally, the main one is probably the autobiographical, where the chief character is the speaker and relates the whole course of his life, as in Defoe's *Robinson Crusoe;* but another important species is the one which covers only that part of the hero's biography which concerns his social and moral initiation into adulthood. Here, Goethe's *Wilhelm Meisters Wanderjahre* is the classical example, and the German term *bildungsroman*, meaning "novel of educational formation," is the most convenient name. It, in turn, has an important subspecies, the *kunstler-roman*, or "novel about the artist's life," of which James Joyce's *Portrait of the Artist as a Young Man* is a supreme example.

All these kinds of biographical novels, except perhaps the last, tend to be panoramic in narrative structure; but as regards characterization, the picaresque novel is like the adventure story in that it mainly employs what Forster has called "flat characters," who are not seen "all round" and who do not develop, whereas the biographical novel proper usually contains at least one fully presented and developing, or "round," character—the hero.

Novels where several characters have equal or at least considerable prominence, as in Jane Austen's, for example, are often dramatic in structure; and their cast is mainly composed of "round" characters. It should, however, be remembered that the majority of minor characters are "flat" in every kind of novel; that the terms themselves are both relative and to some extent subjective; and that, as the example of Mr. Micawber reminds us, "flat characters" may be just as memorable and successful as "round ones"—in characterization much depends on the particular needs and opportunities of the novel's basic structure.

The picaresque novel and the *kunstler-roman* may be regarded as examples of categories based on the class or occupation of the main character; but the same sort of categorizing can be applied to novels which are based on a group of characters rather than on one individual. There is, for example, the political novel, the novel of high life and the novel of peasant life. In some cases this mode of classification determines the essential literary nature of the work: thus the cowboy novel has developed the very strict conventions of plot, character, background and theme which characterize the modern American "western"; but in other cases, the question of the class or occupation of the characters may be quite incidental.

The Author's Intention.—One could, no doubt, establish a large subspecies of novels dealing with marine fishermen; but it would hardly enable us to gut the secrets of Melville's *Moby Dick* or Hemingway's *The Old Man and the Sea*. It is always to the larger emphases that we must attend; and in *Moby Dick*, for example, in spite of the vast amount of information on whales and whaling, the author's main intention is not the study of a particular occupation. Intention is most obvious in the didactic or propagandist novel, of which Harriet Beecher Stowe's *Uncle Tom's Cabin* is the classic example; it has somehow survived, but most didactic or propagandist novels have proved to be as ephemeral as the causes they espoused. Of greater importance in the novel as literature are the intentions which the author may not declare openly, but which may nevertheless be the essence of his novel's meaning. This condition is especially so in many modern novels, where the author rarely confides his views to the audience in the way that Fielding and Trollope did. He may have an attitude to the narrative which is quite different from that of the fictional narrator; an example of this ironic discrepancy between the apparent tenor of the narrative and the very different intention of the author is in Anita Loos's *Gentlemen Prefer Blondes*, where we are not intended to share the narrator's self-complacency but to laugh at it.

More generally, there are many novels where there is an ironic interplay between the meanings that the characters themselves see in their situation and the very different implications intended by the author; perhaps the extreme development of this ironic indirection is in the later novels of Henry James, but all novels probably benefit to some extent if we read them not with an uncritical subjective identification with the characters, but with a degree of dispassionate distance and objectivity.

There are at least two other large categories of fiction which need to be read with an awareness that they are not primarily intended as direct and literal representations of reality: the romance and the fable. Both of them are much older than the novel, but in their modern forms both of them may nevertheless be clothed in sufficient apparent likeness to ordinary life to fall within the category of the novel. In the romance, to which we shall return later, we are given something which may at times look like life in the real world, but which is really idealized in some way; whereas in the fable, it is not so much that the fictional world is an ideal one, but that the essential interest of the narrative lies in some more or less overt general moral lesson which it illustrates, rather than in the narrative for its own sake. Sometimes, as with Christian, the protagonist of Bunyan's *Pilgrim's Progress*, the fact that the characters have allegorical names gives us a clear guide to the author's special intentions; and sometimes, as in Johnson's *Rasselas* or Voltaire's *Candide*, the author's aim is so obviously the discussion and illustration of general ideas that we feel compelled to withhold the name of novel; but in the novels of Hawthorne, for example, it is only a certain consistent lack of density in the narrative line, and a pervasive tendency to generality in the psychological presentation, which tells us that we are in a rather special domain where larger metaphysical issues are the main forces in conflict.

Some critics, such as F. R. Leavis and Richard Chase, have used the term "fable" in a rather wider sense, and have applied it, not merely to novels where the writer's gaze is manifestly directed off stage in the direction of cosmic contradictions and eternal verities, but more widely to all novels where, though we read through them with the sense of their presenting complete and real fictional worlds, we later discover that a definite moral pattern was worked out in the narrative: Jane Austen's novels, for example, can usually be reduced to such an underlying moral fable. This extension of the term has its dangers, but we must recognize that it is impossible to classify and name all the infinite gradations by which different novels range from the total particularity of documentary

realism through the various indirections of allegory and fable and symbolism to the supreme generality of myth.

EARLY MODES OF NARRATIVE AND THE NOVEL

Novel and Epic.—Because of the priority of the epic among the established forms of narrative and the enormous prestige given it by the genius of Homer, theorists of the novel have been much concerned about the relation of the new form to the epic. Fielding, for example, claimed as much as he could of its protecting authority for his new kind of prose fiction, in the preface to *Joseph Andrews* (1742), which was, he announced, "a comic epic in prose." Many later novelists have been inspired by similar ambitions, but it is probable that the analogy has proved too general and abstract to be very helpful.

Epic belongs, essentially, to a more primitive stage of civilization, where large, but not vast, communities have learned the arts of farming and metalworking but still spend much of their time in fighting and raiding each other. Later stages of civilization, of course, imitated primitive epic, as Virgil and many later writers imitated Homer. But in the 18th century critics became aware that epic poetry belonged to a particular kind of civilization; and they eventually saw that this had implications for the emerging form of the novel. Especially was this true in Germany. C. F. Blankenburg's important *Essay on the Novel* led the way in 1774, and later Goethe and Schiller drew a similar but more comprehensive socio-literary contrast: on the one hand there was the ideal harmony between man, nature and the gods which had existed in the golden age of Greece and which was reflected in epic poetry; on the other hand there was modern society, with its urban and bourgeois life, and with the influence of Christianity's self-conscious individualism and its pressing sense of the conflict between divine and secular interests: it was obviously impossible for the novel to reflect anything like the coherence and serenity of the Homeric world. Later, Hegel took the contrast a step further: since modern civilization was inexorably "prosaic," the novel's typical theme had to be the division between the poetic and spiritual aspirations of the individual and the prosaic realities of his existence.

The epic and the novel reflect different societies, and therefore present different kinds of people. As Aristotle pointed out, Greek literature had no literary form which represented people who were neither "better than ourselves," like those of epic or tragedy, nor "worse than ourselves," like those of comedy, but merely "like ourselves"—as the characters of novels usually are. Actually, the only items in our opening definition which the novel shares with the epic are those of size: both are narratives "of considerable length" and both have "plots of more or less complexity"; common usage, indeed, has made "epic" into a mere superlative of scale. As for subject matter, we can only say that the more a novel gives a vast panorama of a whole society, especially one engaged in war, the more it approaches epic. But when we consider how the ultimate power in Conrad's *Nostromo* is capitalism, or how the whole trend of Tolstoi's thought in *War and Peace* is antiheroic, we see how deeply and essentially different the two forms are.

Novel and Romance.—The particular historical and social background of romance tends to confirm the view that the three main forms of narrative correspond to three different phases of civilization. The Greek romances or novels arose long after epic and are associated with the cosmopolitan and commercial cities of the Hellenistic period. Some of the Greek romances related fantastic adventures, like the interplanetary journeys in Lucian's *True History;* but the largest class, of which Heliodorus' *Aethiopica,* in the 3rd century A.D., is the best surviving example, depicted the endless misadventures of a pair of lovers until they were finally reunited.

The rebirth of literature in medieval Europe exhibited the same sequence: heroic literature was succeeded by romantic. The *chansons de geste* of the 11th and 12th centuries dealt largely with fighting; but the more settled and sophisticated life of the later feudal period, with its development of courtly love, produced the chivalric romance, first in poetry and later in prose.

Medieval romance had two new cultural features which were both essentially Christian: the moral idealism of chivalry, and the erotic idealism of courtly or romantic love. Both of these values, of course, were passed on to the modern world, and they provided an important element in its fiction. The medieval romances were so called because they were narrated, not in Latin, but in the romance vernaculars; and the term has persisted in the French, Italian, German and Russian words for a novel; only English makes a linguistic distinction between the fanciful "romance" and the realistic "novel."

For good and for ill, however, the tendencies cannot be wholly separated. For two reasons. As regards content, the spirit of romance, the aspiration for a world of knightly values and romantic loves, is a genuine part, though perhaps a regrettably small one, of the real world. As regards literary form, many novelists have thought that they could better represent the essential truths of life if they dramatized them even at the cost of complete plausibility, or brought them into higher relief by omitting circumstantial details.

Another combination of the novel and the romance, however, merely exploits the confusion of fiction and reality; for what is often called a romance is a form of popular fiction which makes a business of purveying romantic wish fulfillments of the most unreal kind through the apparently realistic medium of the novel.

Realistic Traditions of Fiction.—Convincing reference to the details of ordinary life occurs in early literature, but it is usually casual and sporadic. The major exception to this in classical literature is the largest extant portion of the *Satyricon* of Petronius—Trimalchio's feast. Its masterly picture of the vulgar inanity and ostentation of the life of the *nouveaux riches* in the days of Nero gives us our most complete and intimate knowledge of daily life in classical times—its houses and manners and speech and ultimate social values. As a whole, however, the *Satyricon* is not a unified realistic narrative but a curious miscellany of prose essays dealing with social and literary criticism, of picaresque narrative, incidental bawdy stories and interpolated poems. It belongs to the tradition of Menippean satire which has its modern equivalent in that somewhat marginal kind of novel, of which the classic example is Sterne's *Tristram Shandy,* where the narrative is essentially a pretext for incidental and miscellaneous disquisitions.

The two medieval narrative forms closest to the daily life of the people were primarily for the entertainment of the growing urban middle class. The fabliau, a fairly short verse story, usually concerned with amorous adventures in low life, developed in France during the 12th and 13th centuries: the most famous English example is Chaucer's *Miller's Tale.* But it was for the richer and more cultivated merchant society of 14th-century Florence that the first momentous step toward the modern novel was taken. Giovanni Boccaccio's famous collection of *novelle,* the *Decameron,* established the basis of the modern short story; and something of their narrative skill and psychological veracity is also found in Boccaccio's long prose works, the *Ameto,* the *Fiammetta* and the much longer *Filocolo.*

Both the fabliau and the *novella* tended to take a cynical view of life, which was diametrically opposed to the high-strained idealism of the chivalric romances; even closer to the modern novel are some of the 16th-century works in this antiromance tradition which reflect the ending of the heroic chivalric ideals of feudalism. The picaresque novel was initiated by the anonymous *Vida de Lazarillo de Tormes* in 1554, an autobiographical account of a poor boy's attempts to keep alive by tricking his employers; the form typically offers wonderful opportunities for taking the reader into the most varied social environments and for describing the life there with vivid and often seamy detail.

The full development of the novel, however, required a narrative mode that was less episodic and more rooted in character—the *picaro* himself tends to be merely the sum of his escapades; the novel also had to be able to present the whole of reality, not merely the comic and sordid scenes typical of the picaresque. The first major resolution of these two problems is found in *Don Quixote* (1605, 1615), where Cervantes combined burlesque of

the chivalric romances with certain picaresque elements.

In its formal structure *Don Quixote* is almost as episodic a succession of adventures as the romances it parodied, such as *Amadís de Gaula* (1508); and its predominantly comic mode inhibited a fully realistic treatment of the actions of the hero. Yet when Cervantes juxtaposed the romantic idealism of Don Quixote against both the meagre possibilities of realizing them in the world of contemporary actuality, and the earthy empiricism of Sancho Panza, he resoundingly initiated the novel's endless exploration of the conflict between the ideal and the real as it occurs in the individual's dealings with his environment and his fellow human beings. Nor is this all. The characterization of the two protagonists is not only remarkable in itself, but it is the basis of a progressive psychological interaction which is worked out in narrative terms, and thus foreshadows what is perhaps the novel's richest and most characteristic resources—basing a unified narrative development on the working out of a personal relationship.

So much for the definition of the novel, its classifications and its fictional predecessors; we must now turn to a historical survey of the genre as it developed in Great Britain and the United States. For its development in other countries, *see* the national literature articles—CANADIAN LITERATURE; FRENCH LITERATURE; GERMAN LITERATURE; etc.

THE ENGLISH NOVEL TO 1900

That there is a deeply realistic strain in the English national temper is suggested by its early literature. Chaucer's portraits of the pilgrims and their interplay in *The Canterbury Tales* reveal a genius for the vividly concrete; the same tendency is active in the telling detail and mordant observation found in much other medieval poetry; while Sir Thomas Malory's *Le Morte Darthur*, printed by Caxton in 1485, gives a compelling sense of physical actuality to the legendary material of the Arthurian romances.

Elizabethan Period.—In the 16th century the greatest achievements of English literature were in poetry and drama, but there was considerable activity in many kinds of prose fiction. John Lyly's *Euphues* (1578) is a romantic intrigue told in elegant letters, which are interspersed with general discussions on such topics as religion, love and epistolary style; Lyly's main interest is not narrative or psychological but educational, as is suggested by his hero's name (Euphues is Greek for "well cultivated"), and the very considerable influence of *Euphues* was therefore on literary style rather than on the development of fiction. A similarly rhetorical emphasis marks the most widely admired work of Elizabethan fiction, Sir Philip Sidney's *Arcadia* (1590). Combining elements from three kinds of romance—the Greek, the chivalric and the pastoral—Sidney tells a very long and complicated story composed of separated noble lovers, disguises, oracles, love philtres and hairbreadth escapes, which are set in a conventionalized but beautifully described pastoral landscape.

The same emphasis on complicated adventures is found in many of the less aristocratic prose narratives. Chivalric romances, both translated and original, such as Emanuel Forde's *Parismus, the Renowned Prince of Bohemia* (1598–99), were very widely read, and so were the shorter and more stylish pastoral romances of such writers as Thomas Lodge, whose *Rosalynde* (1590) gave Shakespeare the plot of *As You Like It*, and Robert Greene. But if one wants to catch the note of life as it was lived by the Elizabethans, one must turn elsewhere.

To warn people against the methods of real criminals there arose a literature of roguery; and some of this popular journalistic reporting, notably Greene's "cony-catching" pamphlets, vividly describes the life of the London streets. The picaresque tradition also produced one highly original masterpiece, Thomas Nashe's *The Unfortunate Traveller* (1594), in which the often scabrous adventures of Jack Wilton, an unscrupulous page traveling through the continent, are brilliantly and racily described. But it is the silk weaver and popular balladist Thomas Deloney who gives the most detailed pictures of ordinary domestic life in his three narratives about tradesmen, *Jack of Newbury* (1597), *The Gentle Craft* (i.e., shoemaking; 1597–98) and *Thomas of Reading* (1599). Deloney, however, sets his tale in earlier days; his clothiers and shoemakers, though convincing as characters, are not really developed, and his novels are essentially miscellaneous collections of anecdotes with only a minimal connecting thread. Delony is therefore no exception to the generalization that the Elizabethans, like earlier English writers, were not primarily interested in the kind of faithful representation of ordinary life which is typical of the novel.

The 17th Century.—Under the Stuarts prose fiction continued mainly along the established traditions of the picaresque novel, the romance and the *novella*. The enormously long French heroic romances of the time were much translated and imitated, while Mrs. Aphra Behn wrote some readable "novels"—longish short stories of intrigue, of which the most famous is *Oroonoko* (1688), telling the tragic love of a gallant Negro slave.

Apart from another masterpiece in the same genre, William Congreve's graceful *Incognita* (1692), there is little else in 17th-century prose fiction of note, with the giant exception of John Bunyan. *Grace Abounding to the Chief of Sinners* (1666) is in the established Puritan form of the autobiographical confession, which relates the sinner's life until he finds "the miracle of precious Grace"; the subject of *Pilgrim's Progress* (1678) is similar, but it is cast in the allegorical form of a journey from the City of Destruction to the Gates of Heaven; while *The Life and Death of Mr. Badman* (1680) reveals the ampler opportunities for graphic realism afforded by the exemplarily negative case.

Bunyan's prose style shows the force of popular Puritan preaching combined with the eloquence of the Authorized Version of the Bible; it can accommodate the homely and the sublime, and range with equal conviction from domestic trivialities to the visions of burning faith. Bunyan is thus an excellent example of one of the main arguments of Erich Auerbach's brilliant *Mimesis: the Representation of Reality in Western Literature* (1946; English translation, 1953). Auerbach shows how Christianity's strong egalitarian belief that the souls of all sorts and conditions of men are potentially of equal value produced a narrative tradition quite different from the classical literary theory of the separation of styles, whereby serious treatment was restricted to "noble" subject matter, while everyday reality and humble people were considered appropriate only for comic or satiric treatment. Bunyan presents his humble protagonists with utterly serious realism; on the other hand his allegorical method, the narrative equivalent of the traditional Christian way of interpreting realities in otherworldly terms, is obviously not typical of the novel, which presents secular life for its own sake.

The 18th Century.—Bunyan was a village tinker, and his works were a direct expression of the connection between narrative realism and the increasing articulateness of the tradesmen and shopkeepers who had already shown their power in the Civil War. In 1688, the year of Bunyan's death, the Glorious Revolution finally destroyed the feudal pretensions of the Stuarts and inaugurated the political and social dominance of middle-class commercial interests, of which Daniel Defoe was the foremost spokesman. Though born a Puritan like Bunyan, Defoe reflects the strong secularizing tendency of his time; his pretendedly genuine autobiographical memoirs *Robinson Crusoe* (1719), *Moll Flanders* (1722), *The History of Colonel Jack* (1722) and *Roxana* (1724) are vivid and comprehensive expressions of the social and economic individualism of the Protestant ethic. In form they are loosely episodic biographies of heroes or heroines for whom the quest for middle-class security is the most compelling reality, although it is occasionally in uneasy conflict with other values, notably those of religion and of personal feeling. Helped by his journalistic training, Defoe, much more thoroughly than any previous writer, tried to make his fiction literally convincing; and he also introduced into the tradition of the novel one of its most enduring themes—the struggle of the individual both with the external world and with his own conscience.

Another bourgeois Puritan, Samuel Richardson, has often been credited with the novel's paternity—and probably deservedly, if by this is meant that his works are the first which fit completely into the main fictional patterns of the centuries to come. Defoe had no significant successors but Richardson had many, both in

England and abroad. His *Pamela: or, Virtue Rewarded* (1740) tells in a series of letters how a virtuous servant girl finally constrains her amorous master to marry her: and it is thus the archetype of the commonest kind of novel, that based on the mating process. Richardson's exhaustive treatment of his heroine's psychological states had led him to construct a unified novel out of what would previously have been material only for a short story: and this great extension in psychological depth, continued in *Clarissa: or, the History of a Young Lady* (1747–48), showed how a single personal relationship could be developed to mobilize a rich complexity of larger ethical and social conflicts: *Clarissa* is the first, and one of the greatest, of tragic novels. Finally, in the *History of Sir Charles Grandison* (1753–54), Richardson used the epistolary method for a less intense kind of social and moral analysis.

Henry Fielding was provoked by the sanctimonious moralism of *Pamela* into writing *Joseph Andrews* (1742), a lively comic story about the travels, misadventures and final marriage of Pamela's virtuous brother. *Tom Jones* (1749) is a panoramic novel in which Fielding exhibited his ethical and social views in a large and complex plot; while *Amelia* (1751) is a more sombre treatment of the consequences of marital infidelity and weakness. Fielding is in many ways the antithesis of Richardson: equally serious as a moral and social thinker, his method was essentially humorous, expansive, eclectic and illustrative; it incorporated many elements from the fable, the comic drama and the essay.

The chief immediate successors of Richardson and Fielding were Tobias Smollett and Laurence Sterne. Smollett in *Roderick Random* (1748), *The Adventures of Peregrine Pickle* (1751) and other novels, of which the best is *Humphry Clinker* (1771), developed the primarily comic and satiric novel along picaresque lines: he is most successful, perhaps, in the presentation of eccentrics and grotesques, a characteristic tendency since then in the English novel. Sterne, perhaps the most gifted and certainly the most original of the 18th-century novelists, wrote *The Life and Opinions of Tristram Shandy* (1759–67), a witty, indecent and brilliantly prolonged demonstration of how to entertain the reader without ever giving him the novelistic development he expects.

In the later part of the 18th century the reading public expanded and the number of novels produced increased steadily. Few of them, however, were of much importance apart from Oliver Goldsmith's popular and influential *The Vicar of Wakefield* (1766) and Fanny Burney's *Evelina, or a Young Lady's Entrance Into the World* (1778) and *Cecilia: or, Memoirs of an Heiress* (1782), which showed the natural advantages of feminine novelists for delicate social comedy. The sentimental novels of Henry Mackenzie and the Gothic tales of Horace Walpole, William Beckford, Ann Radcliffe and M. G. ("Monk") Lewis revealed the growing taste of writers and readers alike for strong appeals to the emotions; while toward the end of the century the novel began to be extensively used by Robert Bage, William Godwin and other radicals for overt social and political propaganda.

The Romantic Period.—English romanticism found its main expression in poetry, but Sir Walter Scott's romantic interest in the past brought about the historical novel which soon became extremely popular all over Europe. The first of the series, *Waverley* (1814), shows the clash of the old feudal order of the Scottish Highlands with the rising bourgeois culture of the Lowlands; and Scottish themes inspired the best of his other novels, *Old Mortality* (1816), *Rob Roy* (1818) and *The Heart of Midlothian* (1818).

Jane Austen described her own times and scenes. *Pride and Prejudice* (1813), *Mansfield Park* (1814), *Emma* (1815) and *Persuasion* (1818) are beautifully poised studies of "three or four families in a country village." Combining Richardson's psychological minuteness with Fielding's broader comic method, and basing her plots on courtship and marriage, she initiated one of the greatest and most characteristic traditions of the English novel, that of familiar domestic comedy used to present larger conflicts of moral and social values: George Meredith and E. M. Forster are perhaps her most illustrious successors.

Two other lesser fictional traditions were developed during the romantic period. Mary Shelley's *Frankenstein* (1818) inaugurates the tradition of science fiction on its horrific side; while Thomas Love Peacock's clever and delightful satires, such as *Headlong Hall* (1815) and *Crotchet Castle* (1831), show the capacity of the novel for miscellaneous topical comment.

The Victorians.—During the reign of Queen Victoria the novel became unquestionably the dominant literary genre. The growth of the reading public and the further consolidation of the political, social and literary power of the middle class enabled the great Victorian novelists to command a public of unprecedented size. Largely because readers had much leisure and because the main outlets for fiction were serial publication or sales to the circulating libraries, the Victorian novel was typically very long; many were published in three volumes, and were called "three-deckers." The novel also became family reading, and this made it rather reticent about many subjects, especially sex; more generally, it tended to a comfortably affirmative tone, which often became mawkish and sentimental about the pieties of family life. Nevertheless now that the Victorian age is beginning to exchange the ignominy of being out-of-date for the prestige of being antique, we can begin to appreciate more justly how its fiction had a broad humanity which remained faithful to the real proportions of experience; never more so, perhaps, than in the humour which is so characteristic a feature of the fiction of the period.

Nor can the major Victorian novelists be fairly accused of complacency. Charles Dickens, for example, was a reformer in everything he wrote, attacking a multitude of social, political, administration and economic evils. There are many things in his novels which modern criticism finds it difficult to defend: the melodramatic oversimplification of goodness and badness in *Nicholas Nickleby* (1838–39), the sentimentalism of *The Old Curiosity Shop* (1840–41), the insular and unhistorical bias of *A Tale of Two Cities* (1859); the rambling and often overcomplicated plots. Yet the intensity and the variety of Dickens' imagination and his unique rhetorical gifts make light of these defects; *Martin Chuzzlewit* (1843–44), *David Copperfield* (1849–50), *Bleak House* (1852–53) and *Great Expectations* (1860–61) give what only the greatest literature can give, a comprehensive, personal and enduring vision of the world.

If Dickens is the greatest novelist of the age, George Eliot's *Middlemarch* (1871–72) is probably its greatest novel. Her great gifts of heart and head united with her supreme insight into individual moral development to produce a vast panorama of a Midland community in transition under her impact of the political, social and economic changes produced by the Industrial Revolution; while at the individual level we see the tragic attrition which time and circumstance bring to the generous enthusiasms of those who, like Dorothea Brooke and Lydgate, and like so many Victorians in real life, wish to devote their lives to bettering the lot of their fellows.

William Makepeace Thackeray was Dickens' chief rival; although his more polished but less intensely committed novels have not worn so well, *Vanity Fair* (1847–48) remains a great and permanent achievement. Anthony Trollope, on the other hand, turned his very lack of emotional or imaginative intensity into an advantage for performing one of the main functions of the novel: a balanced and detailed chronicling of many areas of social life, most notably in the six *Barchester* novels (1855–67). Of the four novels of Charlotte Brontë, *Jane Eyre* (1847) maintains its peculiarly powerful spell despite its melodramatic sentimentality; while her sister, Emily Brontë achieved in *Wuthering Heights* (1847) an intensely tragic confrontation of the passions of love, jealousy and hatred.

At a somewhat lower literary level are many other Victorian novelists of real interest and importance. Among the countless novels of social and political enlightenment one should at least mention Disraeli's *Sybil: or The Two Nations* (1845), Charles Kingsley's *Yeast* (1851), Elizabeth Gaskell's *North and South* (1854–55) and Charles Reade's *It Is Never Too Late to Mend* (1856). There is even an element of social reform in the novels of W. Wilkie Collins, whose *The Woman in White* (1860) and *The Moonstone* (1868) are outstanding examples of the story of mystery and detection, just as Robert Louis Stevenson's later *Treasure Island*

(1883) and *Kidnapped* (1886) are classics of the boy's adventure story.

Later in the century, George Meredith's great reputation was based on wit, intelligence and a marked poetic gift; but although *The Ordeal of Richard Feverel* (1859), *The Egoist* (1879) and *Diana of the Crossways* (1885) reveal considerable psychological acuteness and a brilliantly ironic command of the social scene, they now seem to have an almost disabling affectation of manner. The other great novelist of the later part of the century is Thomas Hardy, also a poet and a master of landscape; intensely direct and honest, his tragic novels *The Return of the Native* (1878), *Tess of the D'Urbervilles* (1891) and *Jude the Obscure* (1896), despite the use of somewhat obtrusive coincidences to underline the malignity of fate, give a harrowingly veracious picture of the consequences of sexual frustration and social deprivation.

THE AMERICAN NOVEL TO 1880

General Characteristics.—It was in the novel that American literature first developed its individuality and independence. Lacking intrinsic formal conventions, the novel is immediately and directly responsive to its historical and social environment; and that of the United States until after the Civil War could hardly have been more different from Victorian England. The comparative absence of either a rich cultural heritage, or of complex and long-rooted class distinctions, together with the endless differences of habit, speech and attitude which they entail, meant that the immediate social horizon offered the American novelist less opportunity to develop the kind of realistic notation of the social scene which was the basis of the English (and European) novel of manners. Americans had no "manners" in this sense of the word; but that is not the only reason they did not produce the kind of novel written by Fanny Burney and Jane Austen, Thackeray and Trollope. For, in the last analysis, the novel of manners assumes that the essential values of life emerge from the processes of society; the American novelist, on the other hand, typically felt himself to be alone and quite unable to share the basic assumptions of the people around him: partly because he had no large and cultivated reading public like that in England; partly because his historical past offered him little besides the intransigent moral individualism of Puritanism.

The isolated artist, then, was left with the need to discover his own new world of moral and social values, and he typically attempted the task with a total abandonment to his own personal insight and a very free handling of the traditions of the novel. In an open and endlessly shifting society, of which the life of the frontier was only an extreme example, the loose framework of the romance could suffice, with its picturesque and uninhibiting settings, simplified characterization and episodic plots. For the more speculative and introverted writer the romance could serve equally well, or melodrama's even more simplified rendering of moral and psychological conflict. In either case the novel was stripped of most of its realistically representational baggage—the lonely explorer travels light.

The Early American Novel.—Despite the Puritan objection to fiction as frivolous and worldly, the 18th-century English novels were imported surprisingly quickly after publication. But it was not until 1789 that the first American novel appeared—William Hill Brown's *The Power of Sympathy*. Its epistolary method and its combination of melodrama and sentimentalism reflect the legacy of Richardson. So do the novels of Susanna Rowson (*c.* 1762–1824) and Hannah Webster Foster (1759–1840); but other influences—Fielding, Smollett and Fanny Burney—appear in many other early novels, such as Gilbert Imlay's *The Emigrants* (1793), Hugh Henry Brackenridge's *Modern Chivalry* (1792–1815), and Royall Tyler's *The Algerine Captive* (1797).

The first original talent is usually considered to be that of Charles Brockden Brown, who was inspired by William Godwin's *Caleb Williams* to write several sentimental and Gothic novels. The best is *Wieland* (1798), where the hero, a cultivated Rousseauist, lives in happy domestic retirement until he is transformed into the murderer of his family and an eventual suicide under the combined spells of a family doom, religious mania and a fascinating Godwinian villain who pursues his fell designs on Wieland's peace of mind (and his sister's honour) by means of his skill as a ventriloquist.

James Fenimore Cooper began with an unsuccessful attempt at the novel of domestic manners, *Precaution* (1820). Later he wrote many historical and political novels in addition to the famous "Leatherstocking Tales." Though neither planned as a unit nor written in chronological order, these romances show a coherent and significant development in their hero's life. *The Deerslayer* (1841) and *The Last of the Mohicans* (1826) show Natty Bumppo learning the arts of the hunter and woodsman, and becoming the companion of Chingachgook and other heroic Indians; older in *The Pathfinder* (1840) and *The Pioneers* (1823), he is forced westward before the advancing frontier, and dies in *The Prairie* (1827): progress, represented by mercenary squatters, has made impossible an independent life in harmony with wild nature and primitive but noble Indians. Despite Cooper's many faults of construction, style and characterization, he created one of the great American myths—Natty Bumppo, lonely seeker of a truer way of life which endlessly eludes him.

During Cooper's long literary career—from 1820 to 1851—the number of novels written greatly increased. Many regional novelists appeared, especially in New England, Virginia, the Carolinas; the best of them, and the most prolific, was William Gilmore Simms (1806–70), who wrote of the Revolutionary War and the life of the southern frontier settlements.

The Mid-19th Century.—Subject and attitude were original in Cooper, but the essential structure of the novel remained derivative, mainly from Richardson, the Gothic novel and Walter Scott. With Nathaniel Hawthorne came a highly idiosyncratic adaptation of romance to the exploration of timeless moral perplexities. In his greatest work, *The Scarlet Letter* (1850) the early New England background is not presented with profuse historical details; and even the laws for the punishment of adultery, on which the plot is based, are used mainly as symbols of how in the light of eternal standards, the Puritan code, like human laws in general, is a crude form of ethical justice which takes little account of the complex and problematic nature of psychological reality. These complex realities are suggested in many ways. Hester Prynne's later serene dedication to good works seems the result of openly acknowledging her sin, but she remains unrepentantly ready to elope with her seducer: while her vengeful old husband, though legally guiltless, has apparently committed a more deadly spiritual sin which is symbolically punished by the mysterious growth of a perverted attraction toward his wife's lover, Arthur Dimmesdale.

Essentially the same method, sparing of concrete incident and detail but rich in suggestion of larger issues, is found in the satire on Brook Farm idealism in *The Blithedale Romance* (1852) and in the slow Gothic drama of the ancestral Puritan curse in *The House of the Seven Gables* (1851).

Herman Melville began with a series of successful narratives of his early adventures in the Pacific—*Typee* (1846), *Omoo* (1847), *Redburn* (1849), *White-Jacket* (1850). Melville's subsequent attempt to transcend the phenomenal world—to give "more reality than real life itself can show"—was begun in *Mardi* (1849), and developed more fully in *Moby Dick* (1851) and *Pierre* (1852). It was only after 1920 that the greatness of *Moby Dick* was widely appreciated. Its apparent subject is absorbing enough: the ill-fated hunt of a whaling captain, Ahab, for the white whale which made him lose a leg; but, in addition to this narrative interest, and the extraordinary farrago of miscellaneous information about whales and whaling, we soon become aware that we are on a quest for something even more slippery and deeply submerged than Moby Dick. For what, exactly, has been much debated; Melville was probably attempting to symbolize the impious and fatal attempt of Puritan monomania (Ahab) to extirpate what it sees as evil (the whale) even though it is part of God's creation. D. H. Lawrence in *Studies in Classic American Literature* (1923) defined the essential theme of Melville, and of much other American fiction, as the conflict of passion and morality, and the "evil" whale would stand well enough for the mysterious power and beauty of the instinctive elements in man which are under continual attack

from the organized repression of Puritanism.

Melville's later works, such as *The Confidence Man* (1857) and the novelette *Billy Budd* (published posthumously in 1924), suggest a deepening disillusion with American society and a melancholy resignation to the fated victimization of natural innocence (Billy Budd) by senseless evil and corruption (Claggart).

Melville and Hawthorne are the giants of mid-19th-century American fiction; but the most influential novel of the period was undoubtedly *Uncle Tom's Cabin* (1852). Its author, Harriet Beecher Stowe, also wrote pleasing studies of New England life such as *The Minister's Wooing* (1859); and this preoccupation with the local scene, which has remained very strong in the tradition of American fiction, was continued by such writers as George Washington Cable (1844–1925) in his portrayal of Creole life in Louisiana.

THE MODERN NOVEL

The modern English and American novel, though still distinct in many ways, have been affected by many of the same historical and social influences, while their literary development has been influenced by the fiction of many other countries, notably of France.

Historical Influences.—Many of the differences between the two societies tended to diminish as industrialism and urbanization coloured the whole of American life and as economic expansion and World Wars I and II increased American contact with the rest of the world. In both countries the exploitation of a vastly enlarged reading public by the mass mediums greatly increased the separation between "highbrow" and "lowbrow." This separation, combined with the increasing political and social dominance of a vulgarly philistine class of financiers and industrialists, widened the gap between writers and society almost as much in England as America. No writer since Dickens has been both the best and the most popular; the greatest modern novelists bear on both sides of the Atlantic the same stigmata of alienation and dissent: Henry James, Joseph Conrad, James Joyce and D. H. Lawrence were alike exiles and expatriates.

Literary Influences: Realism and Naturalism.—The increasing separation of the modern novelist from the values and attitudes of his society is reflected not only in the subjects but in the structures of his fiction and in its modes of representing reality. Scott had given the novelist the dignity of the historian; Stendhal aspired to be the chronicler of his century; Balzac, in his *La Comédie Humaine*, set out to be the scientific naturalist of the human species; but it was not until Gustave Flaubert's *Madame Bovary* in 1857 that the novel was given a pattern of conscious technical expertness. The name of realism was soon, and rather unhelpfully, given to the school of Flaubert; it rejected any idealization of "reality" or any concession, in plot and character, to the romantic wishes of the reader or the writer; instead, the novelist was to be a wholly objective recorder of "reality." Realism was thus the logical systematization of the novel's inherent formal assumption—its pretense at the literal, historical truth of what it presents in terms of positivist science.

With Naturalism the process went further. In his *Le roman expérimental* (1880) Émile Zola codified the analogy of the novelist and the scientist: neither of them selects or creates; they merely study and report. Actually, however, the biological determinism of the Naturalists led them to cut off their "slices of life" so as to show characters and environments which reduced life to the most elementary struggles to survive in a social environment whose irresistible power condemned man's efforts to an untragic futility.

Impressionism and the Stream of Consciousness.—As regards narrative structure, Naturalism tended toward the sprawling and the diffuse. But another literary tendency, and one in appearance quite opposed to it, soon appeared, which was sometimes described as Impressionist by Ford Madox Ford and others. Impressionism follows from Flaubert's concern with objective methods of narration, but its quasi-scientific and epistemological bias also relates it to Realism and Naturalism, although its relativist, empirical and subjective doctrine was one which had arisen in opposition to Positivism. The doctrine was clearest in the Impressionist painters, who theorized that the "real" pictorial reality was not the object as it was known to be, but the object as it appeared to the observer under special conditions of atmosphere and illumination; similarly the literary Impressionists made "point of view" the basis of a technique whereby their novels might be not only more shapely than those of the Naturalists, but truer to the individual's actual experience of life.

This general viewpoint received classical critical expression in the essays of Henry James, especially in the prefaces which he wrote to the New York edition of his novels (1907–09). According to James, a novel should be a "direct impression of life"; since the author himself must not appear, an adequately sensitive recording intelligence was needed within the novel; the novelist must also organize his narrative so that virtually the whole novel could be rendered "scenically" and made to happen under the reader's eyes. Modern critical theory of the novel as a form with modes of operation as complex and precise as those of any other literary genre was thus established by James, and criticism of the novel is still mainly operating within his concepts; among his 20th-century disciples are Percy Lubbock in England and R. P. Blackmur in the United States.

James's notion of narrative point of view as an optically accurate reflection of how individuals actually receive their impressions of life was capable of much further extension; and Virginia Woolf both in her later novels and in such critical essays as "Modern Fiction" (1919), took the extreme individualist and relativist direction which is often described as "stream of consciousness" or "interior monologue." Essentially, this attempts to give the reader a series of verbal stimuli which are literal quotations of the flux of impressions passing through the minds of the protagonists. Like any other representational technique this is, in the last analysis, a mere pretense on the part of the writer; but there is no doubt that in James Joyce, for example, or in William Faulkner it is an innovation which has had many triumphs and has now to some extent been absorbed into the narrative idiom of most modern fiction. *See* also CRITICISM.

ENGLAND AFTER 1900

The Edwardian Period.—The influence of the French and later of the Russian novelists began to be felt in England toward the end of the 19th century. George Moore started in the Naturalist tradition, in his Zolaesque *A Modern Lover* (1883), for example, while George Gissing wrote many sombre studies of the darker side of contemporary life, as in *The Nether World* (1889) and *New Grub Street* (1891). Few of the English novelists were much concerned with the problems of technique, however, and their originality came mainly from their content.

This description is on the whole true of the most successful novelists of the Edwardian period—H. G. Wells, Arnold Bennett and John Galsworthy—although Bennett was at first a conscious adherent of the French Realist tradition. In *The Old Wives' Tale* (1908) and *Clayhanger* (1910), he showed his great capacities as a shrewd observer of social and economic life, capacities which he soon turned to making his own fortune by his pen. H. G. Wells wrote novels of many kinds; but his principal aim, in *Tono-Bungay* (1909) for example, was to use fiction as a sounding board for his own radical views of social, political and sexual reform. John Galsworthy began his classic exposure of the Victorian upper middle class in *The Man of Property* (1906), which developed into *The Forsyte Saga* (collected in 1922).

In her essay "Mr. Bennett and Mrs. Brown" (1924) Virginia Woolf suggested that all these Edwardian novelists had been much too busy with the material phenomena of life and their notions about changing the world to concern themselves sufficiently with the truth of individual experience. One of their contemporaries, however, was exempted from this charge—Joseph Conrad, a transitional figure whose deeply personal art combined the old and the new: his plots employed the resources of the adventure story and of melodrama and his essential moral themes were fairly traditional, but in such a novel as *Lord Jim* (1900) the method of indirect narration through Marlow exemplified both the Impressionist technique and the relativist and skeptical attitude to life which it ultimately implies. *Nostromo* (1904), *The Secret Agent* (1907

Under Western Eyes (1911) and *Victory* (1915) were his other greatest novels.

E. M. Forster, another transitional figure, wrote all his novels except *A Passage to India* (1924) before 1914. He used the comedy of domestic manners as his form, but extended its range and added other more modern devices such as the repeated symbol or leitmotiv, as in *Howard's End* (1910); in the liberal humanist tradition, Forster's novels all explored the possibilities of harmony between countries, classes and persons through intelligence, sensitivity and love.

After World War I.—It would be difficult to exaggerate the extent to which this calamity reshaped the ways in which people looked at life: after 1914 it seemed that brutality and increasing social dissolution were the deepest truths about the world, not peace and progress; as for fiction, history had certainly destroyed the leisure and social stability needed for the kind of large-scale development of family and personal relationships on which the Victorian novel had been based.

The two most revolutionary voices among the novelists were those of James Joyce and D. H. Lawrence. They had little in common except the absolute individualism of their lives and their art, which led them both to unprecedentedly frank explorations of private experience, including the animal functions; this in turn brought them both into conflict with the law, and thus converted them into notorious public symbols of literary and moral subversiveness.

D. H. Lawrence began with realistic and fairly traditional novels about the mining towns and countrysides of his native Nottinghamshire, such as *Sons and Lovers* (1913), which recorded with harrowing sincerity the conscious and unconscious results of the hero's emotional attachment to his mother. Later Lawrence became impatient with the careful working out of plot and background in the traditional novel and his fiction became a bolder and freer effort to express the instinctive, inarticulate elements in character and personal relationships; *Women in Love* (1921) and *Lady Chatterley's Lover* (1928) are works of great power, insight and truth.

James Joyce began in the aesthetic tradition, with its cult of the lonely, Godlike creator. *A Portrait of the Artist as a Young Man* (1916) is a brilliantly composed picture of its hero's emergence from the restrictions of family, religion and country into the freedom of the artist. *Ulysses* (1922), probably the most influential and original novel of the period, mainly deals with an advertising-canvasser, Leopold Bloom; there are many intentional parallels with Homer's *Odyssey*, whose main function is as an ironical measure of the degradations of modern life; but what gives *Ulysses* its greatest power is the use of interior monologue to reveal the inmost minds and feelings of the characters as they live, hour by hour, through a Dublin day. Joyce's last work, *Finnegans Wake* (1939), attempts, through a new language and a new mythic mode of narrative, to cover the whole of the recurring cycles of world history in the form of a dream by a Dublin public-house keeper, H. C. Earwicker: Joyce's phenomenal powers as a humorist and a master of language are not in question but the merits of his final effort to revolutionize the novel are.

Virginia Woolf was almost as famous an innovator as Lawrence and Joyce. She developed the consistent stream-of-consciousness method of Dorothy M. Richardson (*Pilgrimage*, 1915–38) in *Mrs. Dalloway* (1925), *To the Lighthouse* (1927) and *The Waves* (1931) in a way which revealed a genius for poetic description of mood and atmosphere. Among the other English writers of the 1920s Aldous Huxley was perhaps the most famous for his intellectual, witty and cynical novels of discussion such as *Crome Yellow* (1921), *Antic Hay* (1923), and his larger scale *Point Counter Point* (1928).

Time will perhaps decide that Ford Madox Ford and Wyndham Lewis were underrated in their day. Certainly Ford's *The Good Soldier* (1915) and his Tietjens series (1924–28) are memorable both for their Impressionist method and for their picture of the decay of the English ruling class during the Edwardian period and World War I; while Wyndham Lewis in *Tarr* (1918), *The Apes of God* (1930) and other fictions remained an uncompromising and powerful critic of the life and literature of his times. On the other hand it may be that the great popular successes of W. Somerset Maugham blinded the critics to the enduring qualities of his novels *Of Human Bondage* (1915) and *Cakes and Ale* (1930).

After the 1920s.—In the novel, as in poetry, the great innovations of the modern period began just before World War I and came to the forefront very soon after it. The subsequent picture was more confused, and no figure with the authority of Joyce or Lawrence established himself. The fiction of the 1930s was much influenced by the atmosphere of political crisis—unemployment at home, fascism and the menace of war abroad. Its most permanent additions to the traditions of the novel were probably those of George Orwell (1903–50) and of the Hungarian-born Arthur Koestler (1905–), whose greatness depended less on their literary qualities than on their political insight.

After World War II the tendency was toward fiction on a smaller scale and in more traditional forms, modified by the technical procedures of such pioneers as James, Conrad and Joyce. Graham Greene (1904–) continued to write melodramas with moral and religious overtones; and Ivy Compton-Burnett (1892–) and Henry Green (pseudonym of Henry Vincent Yorke; 1905–) further developed their sophisticated virtuosity. Among the younger novelists William Golding (1911–), Angus Wilson (1913–) and Kingsley Amis (1922–) established their reputations.

THE UNITED STATES AFTER 1880

To World War I.—In the United States the greatest successors of Hawthorne and Melville were the very different figures of Mark Twain and Henry James, who came to maturity after the Civil War.

Mark Twain (Samuel L. Clemens) began by turning toward the idyllic past, to boyhood, to the west and to the vernacular riches of folk culture. All these are combined in *The Adventures of Huckleberry Finn* (1884) where, in the kinship of young Huck and Jim the old Negro slave, two innocents aboard a raft floating down the Mississippi, one may see a parable of the beauty and the unreality of "the American dream": to them codes, cultures, institutions, history are only interferences with the real things of life; happiness must be sought in the harmony which outcasts can achieve with nature and with themselves, but with nothing else; certainly not with what goes on in the settlements along the river banks. The narrative voice—Huck's vernacular—catches the predestined note of such a theme: its naïve simplicities are equally eloquent in their affirmations of happiness and in their ironic rejections of what man has made of man. This style was to be, as Ernest Hemingway later noted and personally demonstrated, the necessary speech of the naïve, the pastoral, the masculine and the primitivist strains in 20th-century American fiction.

Twain later became the obsessed spectator of the gilded age (which he named); and in such works as *A Connecticut Yankee in King Arthur's Court* (1889), "The Man That Corrupted Hadleyburg" (1899) and *The Mysterious Stranger* (published posthumously 1916), he revealed an uncontrolled revulsion from his increasingly commercialized society. Henry James lived most of his life in the genteel and cultivated Europe which Twain had begun his career by mocking in *The Innocents Abroad* (1869); but James's most persistent subject was nevertheless a sophisticated version of Twain's idealization of American innocence in its perilous exposure to the traditional charms and the infinitely varied corruptions of the society of London and Paris and Rome. Such, in essence, is the story of *The American* (1877) and *The Portrait of a Lady* (1881); while in later works, including *The Ambassadors* (1903), *The Wings of the Dove* (1902) and *The Golden Bowl* (1904), the same contrast is part of a much more complicated moral pattern.

But the international theme is not, of course, James's only subject, as *The Awkward Age* (1899), *What Maisie Knew* (1897) and *The Princess Casamassima* (1886) attest. What his works have in common is that in all of them James managed to be, very intensely, both a passionately involved moralist and a meticulously detached artist; and his novels consequently invite a strenuousness of attention to the complexities both of their fictional organization and of their ethical implication, which many readers have found too much

to give, and to which others have perhaps given too much.

James's friend William Dean Howells was the chief spokesman of the realistic direction which most U.S. fiction began to take after the Civil War. Having realized itself as a country, the United States had to face its problems; they were not unlike those of any advanced capitalist society, and they had already been described by the French Realists and Naturalists. For example, Howells' *The Rise of Silas Lapham* (1885), a study of the attempt of a self-made paint manufacturer to push his family into the Brahmin society of Boston, could well have been treated by Flaubert or Maupassant. After Howells, Stephen Crane's short career produced, most notably, *Maggie: a Girl of the Streets* (1893), a Naturalist study of the degradation produced by the tenement environment of New York; *The Red Badge of Courage* (1895), his famous masterpiece about the Civil War; and many short stories, such as the impressionistic "The Open Boat."

The chief tendency of the first decade of the new century was an angry Naturalism. Frank Norris planned a vast Naturalist trilogy to be called "The Epic of the Wheat": *The Octopus: a Story of California* (1901), dealt with production; *The Pit: a Story of Chicago* (published posthumously in 1903), concerned distribution; the third part, to be called "The Wolf: a Story of Europe," would have dealt with consumption. Norris' writing was sometimes banal and forced, but he was a writer of great power, perhaps because his belief in the determining effect of the environment was accompanied by an equally marked romantic identification with the sheer vigour of man's struggles—a dualism which also vitalizes his novel *McTeague* (1899).

Much of Norris' Naturalism and his note of violent social protest was echoed by Jack London; but Norris' most important successor was Theodore Dreiser. The realism of Dreiser's *Sister Carrie* (1900) caused it to be withheld from publication until 1912; *The Financier* (1912), *The Titan* (1914) and *The "Genius"* (1915) are massive and vigorous studies of a successful tycoon, Frank Cowperwood, and show a progressive identification with the values of wealth and power. Less powerful but more prolific, Upton Sinclair's works included Norrislike studies of particular industries; the Chicago stockyards in *The Jungle* (1906), *King Coal* (1917) and *Oil!* (1927).

After World War I.—Edith Wharton, friend and successor of Henry James, developed the well-made novel of manners. As Howells had already showed, U.S. society was now richly provided with differences of class and habit and tradition; Mrs. Wharton took brilliant satirical advantage of this in such novels as *The House of Mirth* (1905) and *The Custom of the Country* (1913). Many other writers who had begun before the war made or increased their reputations afterward, notably Willa Cather, Ellen Glasgow (1873–1945), James Branch Cabell and Booth Tarkington; but the most distinctive note of the postwar years was struck by writers who had just come to manhood; the war and the America of Coolidge turned them away from interest in political and social reform and toward the exploration of themselves, and above all of the small groups of like-minded, world-weary yet very convivial dissenters which are a characteristic feature of the life and the fiction of the 1920s.

F. Scott Fitzgerald is the legendary symbol of what Gertrude Stein dubbed "a lost generation," and the most representative voice of the jazz age, whose fortunes are suggested by the arc of Fitzgerald's own literary development, from *This Side of Paradise* (1920), *The Beautiful and Damned* (1922) to *The Great Gatsby* (1925), *Tender Is the Night* (1934) and the unfinished *The Last Tycoon* (1941). The complex economy of *The Great Gatsby* embodies a great theme of the American novel—the corruption and defeat of a naïvely romantic midwestern emigrant against a setting of the squalors of society both high and low.

Ernest Hemingway's *The Sun Also Rises* (1926; published as *Fiesta* in England) dealt with the American expatriates of Fitzgerald's generation; but in *A Farewell to Arms* (1929), *For Whom the Bell Tolls* (1940) and many other novels and short stories Hemingway's heroes and their idiom—an artfully laconic understatement—exhibit a brutal and increasing alienation from civilization, and form a connecting link between the earlier American primitivism of Cooper and Twain and the "tough guys" of modern popular fiction.

The chief contemporaries of Fitzgerald and Hemingway were Sinclair Lewis and William Faulkner, both, like Hemingway, winners of the Nobel prize. Lewis wrote realistic and satiric exposures of midwestern life in *Main Street* (1920) and *Babbitt* (1922), of medicine in *Arrowsmith* (1925), and of religion in *Elmer Gantry* (1927). William Faulkner, on the other hand, was a much more original and powerful writer especially in *Sartoris* (1929), *The Sound and the Fury* (1929), *As I Lay Dying* (1930), *Sanctuary* (1931), *Light in August* (1932) and *Absalom, Absalom!* (1936). Many of his later works, such as the trilogy on the rise of the Snopeses—*The Hamlet* (1940), *The Town* (1957) and *The Mansion* (1959)—continued his study of Yoknapatawpha county, while *A Fable* (1954) is a parable of Christ's Passion.

The depression of the 1930s reinforced the radical and naturalist traditions. John Dos Passos produced a vigorous and original panorama of American life through the first three decades of the century in *U.S.A.* (1930–36). James Farrell wrote the *Studs Lonigan* trilogy (1932–35), an impressive study of the impact of the Chicago environment on a young man. John Steinbeck's *The Grapes of Wrath* (1939) is a memorable picture of the struggles of migrant farm workers in California.

Among the other important writers of the 1930s, Thomas Wolfe, with his sprawling autobiographical narratives, demands notice; while it is ironical to observe that the tendency toward the radical proletarian novel had some influence on Erskine Caldwell, whose *Tobacco Road* (1932) and *God's Little Acre* (1933) were to become the world's all-time best-sellers among works of fiction.

After World War II the general level of technical narrative skill was remarkably high, and Thornton Wilder (1897–   ), James Gould Cozzens (1903–   ), Robert Penn Warren (1905–   ), and Walter Van Tilburg Clark (1909–   ) added to their considerable reputations. Among the many distinguished novelists who established themselves in the 1950s the following should certainly be mentioned: Ralph Ellison (1914–   ), Bernard Malamud (1914–   ), Saul Bellow (1915–   ), J. D. Salinger (1919–   ), Norman Mailer (1923–   ) and James Baldwin (1924–   ).

NOVELLO, the name of an English musical family of Italian origin.

VINCENT NOVELLO (1781–1861), composer and publisher, was born in London on Sept. 6, 1781. From 1797 to 1822 he was organist at the Portuguese embassy chapel, where he directed the first English performances of Masses by Haydn and Mozart; from 1840 to 1843 he was organist at the Roman Catholic chapel at Moorfields. An original member of the Philharmonic society, he had a distinguished circle of friends, including the Lambs, Leigh Hunt, Shelley and Keats. Novello was a prolific composer, but his work as editor and publisher forms his chief title to fame. His *Collection of Sacred Music*, in two folio volumes, appeared in 1811 and marks the founding of the publishing house of Novello. In 1849 he went to live at Nice, where he died on Aug. 9, 1861.

JOSEPH ALFRED NOVELLO (1810–1896), eldest son of the above, was born in London on Aug. 12, 1810, and died at Genoa on July 16, 1896. He began his career as a bass singer but in 1829 he became active in music publishing, his first important work being *Purcell's Sacred Music*, begun by his father in the previous year. It was he who developed the house of Novello and who introduced inexpensive editions of large-scale choral works to England. In 1857 he retired to Italy, leaving the business to be managed by Henry Littleton, formerly his assistant, who subsequently bought it and expanded it with marked success. After Littleton's death in 1888 his descendants carried on the business.

CLARA ANASTASIA NOVELLO (1818–1908), fourth daughter of Vincent Novello, was born in London on June 10, 1818. One of the most famous sopranos of her time, she received high praise from Mendelssohn, Schumann and Rossini. In 1843 she married Count Gigliucci and retired for a time to Italy, resuming her professional career in 1850. She died in Rome on March 12, 1908. (H. Ru.)

NOVEMBER, the 11th month of the modern calendar, with 30 days. It was the ninth month (Lat. *novem* "nine") in the early Roman calendar, which began with March. The attempt of the Roman senate to rename it in honour of Tiberius provoked his reply, "And what will you do if you have thirteen Caesars?" In the churches of western Christendom Nov. 1 and 2 are celebrated as All Saints' and All Souls' day, respectively, perhaps replacing an old Celtic feast of the dead. (*See* HALLOWEEN.) The end of World War I is commemorated on Nov. 11. In the United States the fourth Thursday of the month is a national holiday, Thanksgiving day (*q.v.*). *See* also CALENDAR. (F. R. Wn.)

NOVENA, in Roman antiquity (Lat. *novendial*), a nine-day festival solemnized on the occasion of a prodigy announcing misfortune (especially a shower of stones); also, more commonly, the nine days' mourning following the death of the emperor or other personages. In Christian usage the term designates a spiritual devotion consisting in the recitation of a set form of prayer for nine consecutive days, in petition for a divine favour or in preparation for a liturgical feast or other important event; *e.g.*, a jubilee. The nine days recall the similar time spent by the apostles in prayer, "with the women and Mary," in preparation for the gift of the Holy Spirit (Acts i, 13–14). Novenas were known in the middle ages, but their popularity dates from the 17th century; especially popular was the novena before the feast of the Immaculate Conception (Dec. 8). Today the Novena of Grace, so called (March 4–12, in honour of St. Francis Xavier), is perhaps the best known. Recent proliferation of novenas in honour of the saints is deprecated by those engaged in the liturgical movement. (J. C. My.)

NOVERRE, JEAN GEORGES (1727–1810), was a distinguished French choreographer, whose revolutionary *Lettres sur la danse et sur les ballets* (1760) crystallized 18th-century ideas on the need for important reforms in ballet production. Noverre stressed the importance of dramatic motivation, and decried overemphasis on technical virtuosity. Born in Paris, April 29, 1727, Noverre studied under Louis Dupré, made his debut at Fontainebleau in 1743 and danced in Berlin and Lyons. His first notable choreographic success was *Fêtes Chinoises* (Paris, 1754). This production attracted the attention of David Garrick, who presented it at Drury Lane, London, in 1755.

Noverre was court ballet master at Stuttgart from 1760 to 1767, producing such masterpieces as *Medée et Jason* and *Psyché et l'Amour*. He was summoned next to Vienna where his powerful dramatic ballets *Adele de Ponthieu, Les Horaces* and *Apelles et Campaspe* effectively incorporated his theories. In 1776, on the recommendation of Marie Antoinette, his former pupil, he was appointed ballet master at the Paris Opéra, fulfilling a life-long ambition. He died at St. Germain, Oct. 19, 1810.

Noverre's *Lettres* have been translated into many languages, including English, German, Czech and Korean. His ideas are still valid and constitute an eloquent plea for dramatic expressiveness in the dance.

See Derek Lynham, *The Chevalier Noverre, the Father of Modern Ballet* (1950). (Ln. Me.)

NOVGOROD, a town and administrative centre of Novgorod *oblast* in the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on the Volkhov river, about two miles below its outfall from Lake Ilmen and about 110 mi. S.E. of Leningrad. Pop. (1959) 60,669. It is one of the most ancient and historically important towns of Russia.

The main feature is the kremlin (originally known as *detinets*) on the Sofiskaya Storona, the west (left) bank of the Volkhov. First mentioned in 1044, it was extended in 1116. In the 14th century the first stone wall was built. The present walls, with a circumference of more than 1,500 yd., have nine towers. Within the kremlin is the cathedral of St. Sophia, first built of wood in 989. The present building dates from 1045–50 and, although restoration was carried out in the 19th century, it remains one of the finest examples of early Russian architecture. Of special note are the great bronze doors, dating from the 12th century and probably of Byzantine workmanship. Also in the kremlin is the Granovitaya palace (1433), the bell tower (1443) and the little chapel of St. Sergius, also of the 15th century. Another chapel, that of St. Andrew Stratilata, dates from the 17th century as do several other minor buildings. A park has been laid out, surrounding the kremlin.

On the opposite bank of the Volkhov, the Torgovaya Storona, stands the cathedral of St. Nicholas, dating from 1113 and decorated by exterior frescoes. Also of the 12th century are the cathedral of the Nativity of Our Lady, located in the former Antoniev monastery, downstream on the Volkhov; the cathedral of St. George, on the shores of Lake Ilmen in the former Yuriev monastery; the church of St. John (1127); and the church of the Assumption (1135–44). In and around Novgorod, despite damage in World War II, there still survive many other old churches. Of particular note are the church of St. Theodore Stratilata (1360–61), the church of the Transfiguration (1374) and the Znamenski cathedral of the 17th century. From the 18th century dates the Putevoi palace. In 1862 a monument designed by M. O. Mikeshin was raised in the kremlin to commemorate the 1,000th anniversary of Russia. The town has a pedagogic institute.

Novgorod's industries are relatively small and include timber working (furniture and match making), the manufacture of clothing, knitwear and chinaware, fish canning and the repair of river craft. Communications are good, with rail connections to Leningrad, to Luga on the Leningrad-Riga line and to Chudovo on the Moscow-Leningrad line. Novgorod stands on the main Moscow-Leningrad highway, where a road branches to Pskov. The Volkhov is navigable for small craft.

History.—Novgorod is first mentioned in chronicles for the year 862, but its origins are obscure. Archaeological discoveries show the existence of a fortress in the 9th–10th centuries and testify to the growth of Novgorod's trade district (*Torgovaya Storona*) in the 10th century, but there appears to have been an earlier fort-settlement, or *gorodische*, on the shores of Lake Ilmen. The first recorded ruler of Novgorod was Rurik, who was a Varangian, or Norseman, invited by the people of Novgorod to be their prince. In 882 his successor, Oleg, captured Kiev and moved his capital there. Again in 980 the prince of Novgorod captured Kiev, but in general the supremacy of the Kievan princes

was recognized. In 989, under Vladimir, the inhabitants of Novgorod were forcibly baptized. In 1019 the Kievan grand prince Yaroslav granted the town a charter, the Russian law (*Russkaya pravda*), which gave it self-government. The assembly of the townspeople, known as the *veche*, elected their prince. His function was little more than that of military commander and he could be, and often was, removed by the vote of the *veche*. After the death of Vladimir II Monomakh (1125), when the political and economic power of Kiev began to disintegrate and when Suzdal in the northeast had not yet grown strong enough actively to interfere with its western neighbour, Novgorod began to liberate itself from the control of Kiev and work out the pattern of its freedom. From 1270 on, the *veche* elected only a magistrate or burgomaster as its ruler. Sovereignty resided in the town itself, which was quaintly styled *Gospodin Veliki Novgorod* ("Lord Novgorod the Great").

During that period Novgorod flourished as a great trading centre on the "water road," the route from the Baltic to Byzantium, via the Volkhov, Lovat and Dnieper. Trade also went across the portages of the Valdai hills to the Volga and down that river to the Caspian sea and central Asia. The great staple of Novgorod trade was furs, but amber from the Baltic, honey, wax and slaves were also sent south. Return cargoes were mostly luxury goods, gold and silverware and silks. In their search for furs, the town's traders penetrated far into northern Russia and into the basin of the Northern Dvina, then known as Zavolochie, the "land beyond the portage." They even crossed the northern end of the Urals into the northwestern corner of Siberia. Later, in the 12th century, "daughter" towns, Vologda and Vyatka, were founded in these northeastern regions and in time they became independent. The trade of Novgorod was carried on by organized guilds of merchants, each living in its own section of the town. There was a close link with the Hanseatic league and the town derived no little importance from its position as the farthest point to which the Hanse merchants could trade into Russia.

With the decline in power of the Kievan princes, Novgorod was frequently engaged in struggles with the other towns of Russia. In the 12th century there was a prolonged struggle with Suzdal, the main source of grain for Novgorod. In 1169 and again in 1216 the Novgorodians defeated the forces of Suzdal. Meanwhile the growing power of Sweden and the Teutonic Order began to threaten Novgorod from the west. To aid the town against them, the people of Novgorod called on Alexander (*q.v.*) (Nevski), prince of Vladimir, and under his leadership defeated the Swedes on the Neva in 1240 and the Teutonic Order on the ice of Lake Peipus in 1242. Thereafter the town, although still electing its own magistrate, acknowledged the authority of the princes of Vladimir. In the great Tatar invasion of 1238–40, the Tatar armies under Batu Khan came within 60 mi. of Novgorod, but the onset of the thaw on the marshes around the town deterred them and the town was saved from the destruction which overwhelmed most other Russian towns. In the 14th century Novgorod began a long struggle for supremacy with the rising power of Moscow. To the southwest, Lithuania was the new power and Novgorod enlisted its aid against Moscow. In 1332 and again in 1386, under Dimitri Donskoi, Moscow launched attacks on Novgorod. Despite the constant wars and the natural disasters of fire in 1340, 1385 and 1388 and plague in 1390, it is said that the population of Novgorod in the 14th century numbered 400,000 and that there were more than 200 churches.

During the first three-quarters of the 15th century Novgorod was one of the main bones of contention between Lithuania (united with Poland in 1385) and Moscow. In the first three decades the Lithuanian prince Vytautas repeatedly tried to annex Novgorod; but after his death (1430) Novgorod was peacefully wooed by Casimir IV Jagiello, king of Poland and grand prince of Lithuania. Because it harboured his enemies during the civil war and accepted Lithuanian princes, Basil (Vasili) II, grand prince of Moscow, declared war on Novgorod and defeated its forces in 1456; the republic then lost its right to carry on independent diplomatic relations with foreign powers. The first eight years of Tsar Ivan III's reign were marked by acts of open insubordination toward Moscow and illicit relations with Lithuania. At the end of the 1460s the pro-Lithuanian party under Marta Boretskaya asked Casimir IV to annex the city and to submit the archbishop to the jurisdiction of the pro-Uniate metropolitan of Kiev; but before Casimir could offer effective aid, Ivan, in order to "save" his so-called patrimony from the enemies of Orthodoxy, marched on the city, defeated the Novgorodians (1471) and forced them to renounce all dealings with Lithuania and to cede large portions of their northern colonies. Yet Novgorod still remained technically a "free city." In 1477 the *veche*, now under control of the still vigorous anti-Muscovite faction, refused to recognize Ivan's sovereignty. Ivan mobilized his army, surrounded Novgorod and forced it to accept his terms (Jan. 1478). He removed the *veche* bell, the symbol of freedom, confiscated large areas of church land and established his full sovereignty over the city. Even so, opposition to Moscow still continued, until in 1570 Ivan IV "the Terrible" crushed the city, massacring many thousands and deporting the survivors.

In 1611 Novgorod was captured by the Swedes, but in 1617 it was returned to Russia by the treaty of Stolbovo. In 1701 Peter I the Great had Novgorod fortified, but his founding of St. Petersburg replaced its function as a link with the Baltic and the town declined to a minor regional centre. In 1727 it was made seat of a *gubernia* (province). During World War II, from Aug. 1941 to Jan. 9, 1944, Novgorod was occupied by the Germans, and the greater part of the town was reduced to ruins. After the war, not only was the town rebuilt but also the many architectural relics of its long past were carefully restored.

Novgorod Oblast covers an area of 55,299 sq.km. (21,351 sq.mi.) and was formed in 1944 from Leningrad *oblast*. Across it from north to south are the Valdai hills, the line of terminal moraines of the last glaciation, which reach a height of 1,053 ft. in Mt. Kamennik in the extreme south. West of the Valdai hills is the extensive basin of Lake Ilmen, into which a large number of rivers flow, notably the Msta from the east, the Lovat from the south and the Shelon from the west. The outlet for the lake the Volkhov, flows north to Lake Ladoga. A high proportion of the basin is covered by swamp of grass marsh or peat bog. East of the Valdai hills is another swampy lowland in the upper basin of the Volga and drained by the Kobozha and Mologa. There are innumerable small lakes on the Valdai hills. The whole area is covered by glacial deposits, giving an alternation of low, often sandy, mounds and swampy boulder clay hollows. The climate is continental, modified by maritime influences from the west, with January average temperatures about −5° C. (23° F.) and July averages about 17° C. (63° F.). Rainfall is about 20–24 in. a year. The natural vegetation, apart from the swamp areas, is mixed forest of spruce, oak, pine (especially on sands), birch, maple and lime. Along the rivers are extensive floodplain meadows. Soils are usually podsols, often acidic and of low fertility.

The *oblast* population in 1959 numbered 736,529, of whom 251,399 (38%) were urban. The 8 towns and 17 urban districts are all small, the more notable, after Novgorod, being Staraya Russa and Borovichi. Industry is chiefly concerned with timber exploitation, producing sawtimber, paper, pulp and matches, and with primary flax processing. Some cotton cloth is made at Borovichi and cotton thread at Kulatin. Glass and china are also made. Near Borovichi a little lignite is mined. Agriculture, because of the extensive swamps and infertile soils, is weakly developed. Less than 9% of the surface is under the plow. Oats, rye, flax and potatoes are the main crops. Dairying is far more important, especially to supply Leningrad. Since 1870 considerable areas of swamp have been drained, chiefly for pasture or improved forest.

The *oblast*'s chief traffic arteries, rail and road, run northwest-southeast across it between Leningrad and Moscow. The Tallinn-Pskov line to Bologoye (on the Moscow line) crosses it from west to east. *See* also references under "Novgorod" in the Index.

(R. A. F.; X.)

NOVI PAZAR, a town in Dezevski *srez* (district), of the Socialist Republic of Serbia, Yugos., lies at the head of the fertile

valley of the upper Raska on the site of the ancient Serbian city of Rascia (Ras), 115 mi. S. of Belgrade. Pop. (1961) 20,712. There are Roman baths in the vicinity. The 9th-century church of St. Peter, one of the oldest religious buildings in Yugoslavia, is an interesting example of early medieval Slav architecture. Nearby is the famous monastery of Sopoćani (dating from 1285) with vast frescoes portraying the Gospels. Agriculture is the main economic activity and there is a trade in fruit and timber. The town was captured by the Turks in the 15th century and became the seat of a sanjak. It was taken by the Serbs and Montenegrins during the Balkan Wars (1912–13) and was assigned to Serbia by the treaty of Bucharest (1913). Novi Pazar has road links with the valley of Ibar. (V. De.)

NOVI SAD (German Neusatz; Hungarian Újvidék), administrative centre of the Autonomous Province of Vojvodina and of Novi Sad *srez* (district), Yugos., is situated on the left bank of the Danube opposite the historic fortress of Petrovaradin about 47 mi. N.W. of Belgrade. Pop. (1961) 102,385. Novi Sad originated in 1690 as a fortress settlement and became a fishing village. In 1748 it attained city status and was named Novi Sad. During the Hungarian Revolution (1848–49), the town was partly destroyed. After World War I, it was incorporated with the province into Yugoslavia and during World War II it was occupied by Hungarian troops. It was for long the focus of Serbian culture, especially after the foundation in 1826 of the Matica Srbska (Serbian Literary society), and has a university (established 1960), a pedagogical college, an opera house, an art gallery and several museums and archives. It has excellent communications with central Europe via the Danube canal system and by road and railway. The city developed as the economic centre for agricultural products of the fertile Backa plain, but there has also been considerable industrial growth, *e.g.*, the manufacture of porcelain, textiles, electrochemical equipment and agricultural machinery. (V. De.)

NOVOCAIN: *see* Procaine Hydrochloride.

NOVOCHERKASSK, a town in the Rostov *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands at the confluence of the Tuzlov river with the Aksai, a distributary of the Don, 33 mi. N.E. of Rostov-on-Don. It is on the Rostov-Shakhty-Voronezh railway and the main highway between Rostov and the Donets basin (*q.v.*). Pop. (1959) 95,453. The original town, Starocherkasski, stood on the Don, but it was frequently inundated and moved to its present site in 1805, becoming the capital of the Don Cossack region. It was a centre of the anti-Bolshevik movement (1917–20) and during World War II was occupied by the Germans (1942–43). Its industries produce electric locomotives for main-line and factory use, machine tools, iron castings, butter and fats, flour and alcohol. There are polytechnic and agricultural teaching institutes and research institutes of hydrochemistry, hydrotechnology, reclamation and vine growing. (R. A. F.)

NOVOKUZNETSK (formerly Stalinsk), a town in Kemerovo *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on both banks of the Tom river, just below its confluence with the Kondoma, in the Kuznetsk basin (*q.v.*) industrial area. Pop. (1959) 376,730. Originally the small village of Kuznetsk, founded in 1617, stood on the right bank, with about 4,000 inhabitants in 1926. In 1929, under the first five-year plan, an iron and steel works was founded on the opposite bank. Round the works a new town, Novo (New)-Kuznetsk grew up, which was renamed Stalinsk in 1932. Development was extremely rapid and the fully integrated plant became one of the largest in the U.S.S.R. The town is now the largest in the Kuznetsk basin; in 1961 its name reverted to Novokuznetsk. As well as iron and steel it produces aluminum, using bauxite from the nearby Salair deposit.

Large-scale coal mining is carried on round the town and supplies coking coal for the blast furnaces. There is a chemical industry, using by-products, while slag is used in making cement. The main heavy-engineering manufactures are mining machinery and bridge girders. Novokuznetsk has metallurgical and pedagogic institutes. (R. A. F.)

NOVOMOSKOVSK (formerly Stalinogorsk), a town of Tula *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., lies 40 km. (25 mi.) S.E. of Tula, on the shores of (Lake) Ivan-Ozero on the upper Don. Pop. (1959) 106,738. Originally the small settlement of Bobriki, the town was founded in 1930 and developed rapidly as a major centre of the chemical industry. In 1934 it was renamed Stalinogorsk. In 1961 the name was changed again to Novomoskovsk. It lies in the Podmoskovny coal basin, and lignite is mined there, which is used in a large thermal power station. Natural gas, brought by pipeline from the north Caucasus mountains, is used in the chemical industry, which produces fertilizers. There is a mining-machinery factory. (R. A. F.)

NOVOROSSISK, a town in Krasnodar *krai* of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on the Black sea coast, at the head of Tsemes bay (Tsemesskaya Bukhta) and at the foot of the western extremity of the Caucasus mountains, 60 mi. W.S.W. of Krasnodar town. Pop. (1959) 93,461. In 1838 the Russians founded a fortress there, but its importance as a port grew steadily, especially after the coming of the railway in 1888. Before the Revolution, Novorossisk was the largest grain-exporting port of Russia after Odessa. It is still a major port with a naval base, shipbuilding yards, refrigeration plant and grain elevators. Cementmaking is important, with four large factories producing 12% of the Soviet output. Other industries are flour milling, fish processing and light engineering. It was occupied by the Germans (1942–43) during World War II and suffered severe damage. (R. A. F.)

NOVOSHAKHTINSK, a town in Rostov *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on the small Maly Nesvetai river, 57 km. (38 mi.) N.N.W. of Rostov-on-Don on the Rostov-Donets basin highway, and is also connected by a branch line to the main Rostov-Donets basin railway. Its population (103,566 in 1959) had more than doubled since 1939. It is one of the chief mining centres of the eastern end of the Donbass coalfield which is particularly rich in anthracite. Novoshakhtinsk has also an important chemical industry, and there are production of sewn goods, brewing, flour milling and the processing of dairy products. (R. A. F.)

NOVOSIBIRSK, an *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., was formed in 1937. It lies in western Siberia and until 1943–44 included large areas that now comprise Kemerovo and Tomsk *oblasts*. Present area 68,803 sq.mi. Pop. (1959) 2,298,481. The eastern part of the *oblast* lies in the basin of the Ob, which crosses it from south to north, but the greater part is drained toward the west by the Om and Tara to the Irtysh. The large Lake Chany is a basin of inland drainage, receiving two rivers of some size, the Kargat and Chulym. Almost the whole *oblast* is an extremely level plain, known in the north as the Baraba steppe (Barabinskaya Step) and in the south as the Kulunda steppe (Kulundinskaya Step). It is exceptionally swampy and there are innumerable lakes. Only on the Ob plateau, east of the Ob, does the land rise slightly. The climate is severely continental, with summer temperatures averaging about 21° C. (70° F.) and rising to maxima of 35°–41° C. (95°–105° F.); winter averages are about −18° to −20° C. (0° to −4° F.). Vegetation and soils range from taiga on podsol soils in the north, through forest steppe, with groves of birch on gray forest soils, to true steppe on chernozem.

Fifty-five percent of the population (1,275,539) are urban, living in 12 towns and 10 urban districts. Nearly three-quarters of these live in the administrative centre of Novosibirsk, where all the important industry is concentrated. Other towns are small, local agricultural centres, mostly concerned with food processing. The main agricultural area is the Kulunda steppe, of which a high proportion is under cultivation. Spring wheat is by far the most important crop, occupying half the arable land. Other crops are oats, barley and sunflowers. In the Baraba steppe, with its extensive natural pasture, dairying is dominant. Some of the swamp was reclaimed between 1895 and 1917, and part of this work has been reconditioned. In the north, arable farming is again significant, with wheat, rye and flax the most important crops. Fishing is important in the Lake Chany region. (R. A. F.)

NOVOSIBIRSK, a town and *oblast* administrative centre of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on the right bank of the Ob, at the confluence of the Inya. With a population (1959) of 886,470, it is the largest town in Siberia. It developed after the village of Krivoshchekovo on the left bank was chosen as the crossing point of the Ob for the Trans-Siberian railway in 1893. In 1895 the new settlement, Aleksandrovski, was renamed Novonikolayevsk, which it was called until 1925. In 1897, when the rail bridge was completed, the population was 7,832. In 1904 it was made a town. By 1911 the population was 63,000 and by 1939 it had increased to 405,000. Industry has grown with the town and was especially stimulated in World War II, when many factories were evacuated to this area. Engineering takes first place, producing heavy machinery, hydraulic presses, mining equipment, instruments, agricultural machinery, turbines and electrothermal equipment. There are ship and locomotive repair works. Metal for these factories is partly supplied by a rolled-steel mill and large tin works in Novosibirsk. There is an important chemical industry, producing plastics and pharmaceutical goods. Consumer products include cotton cloth, knitwear, footwear, leather goods and furniture, as well as a range of foodstuffs. There are two thermal power stations and, just above the town, the great Novosibirsk barrage and hydroelectric station, with a capacity of 400,000 kw. Novosibirsk is a major communications centre, with railways to the Kuznetsk basin and Barnaul, as well as the Trans-Siberian. The Ob is navigable and there is a large airport. The town is rapidly developing as the cultural focus of Siberia, especially since the founding of its university in 1959 and of the Siberian branch of the Academy of Sciences. There are institutes of railway engineers, water transport, electrotechnology and communications. (R. A. F.)

NOWELL, ALEXANDER (*c.* 1507–1602), dean of St. Paul's cathedral, London, who incurred the royal disfavour for his tactless preaching, was educated at Brasenose college, Oxford, where he may have shared rooms with John Foxe, the martyrologist. He became master of Westminster school (1543) and prebendary of Westminster (1551). In Mary's reign he was deprived of his prebend and sought refuge at Strasbourg and Frankfurt, where he developed extreme puritan views. He accepted the Elizabethan religious settlement, however, and was rewarded in 1560 with the deanery of St. Paul's, where he remained until his death on Feb. 13, 1602. His relations with Elizabeth I were on several occasions unfortunate. Once (1562) she took objection to a prayer book which he had put for her use, because it contained pictures of saints. Another time (1564), when he preached against the crucifix with obvious allusion to the one she kept in the royal chapel, the queen interrupted his sermon. He is generally regarded as the author of the catechism inserted before the order of confirmation in the Prayer Book of 1549—his "small" catechism—which, supplemented in 1604, is still the official catechism of the Church of England. Early in Elizabeth's reign he wrote a "larger" catechism which was printed in 1570, and in the same year appeared his "middle" catechism, designed for use in schools.

NOWGONG, a town and district of Assam, India. The town, headquarters of the district, is on the Kalang river, 74 mi. E.N.E. of Gauhati by rail. Pop. (1961) 38,600. There are two colleges affiliated to Gauhati university, a technical school and a nursing and midwifery training centre. Nowgong is a large producer of jute.

NOWGONG DISTRICT (area 2,167 sq.mi.; pop. [1961] 1,210,761) is largely a plain, encircled by thick forest with the Brahmaputra river on the north. It is intersected by the Kalang river and its tributaries, and is much affected by floods. Numerous marshes and small lakes occur, some notable for fisheries. Teak, sal and lac are valuable forest products. Shifting cultivation in the hills is practised by the Mikir and Kachari tribes (*qq.v.*). Jute and some silk are produced. The chief crops include rice, tea and mustard seeds. Bordowa is a holy place for Assamese Vishnuites (Vaishnavites), being the birthplace of Sri Sri Shankardeva; Silghat on the Brahmaputra is a river port and the rail terminus of a branch line. Raha village is well known for brassware. Lumding in the south is an important junction of the North East Frontier railway. (M. BA.)

NOWY SACZ, a town in Cracow *wojewodstwo* (province) southern Poland, lies on the Dunajec, a tributary of the Vistula, about 115 km. (71 mi.) S.E. of Cracow by road. Pop. (1960) 34,000. It is in a Carpathian valley (Kotlina Sadecka) famed for its apples. Nowy Sacz was founded in 1292, as a result of a privilege granted by Waclaw II, who moved the town of Sacz to a new and more defensible site at the crossing of two old routes, along the Carpathians, and from the north to Hungary (now used by the railway lines), and this helped its development. It developed as an administrative and regional cultural centre and has a metal industry. It is also a tourist centre because of its fine old buildings and the attractive surrounding district. (T. K. W.)

NOYES, ALFRED (1880–1958), English poet, a traditionalist in his literary tastes and remembered chiefly for his lyrical verse, was born at Wolverhampton, Staffordshire, on Sept. 16, 1880, and educated at Exeter college, Oxford. While still an undergraduate he published his first book of poems, *The Loom of Years*, in 1902. Encouraged by George Meredith and others he produced further volumes such as *Forty Singing Seamen* (1907) and *Drake* (1908), which showed patriotic fervour and a love for the sea. In 1913 he went to the United States on a lecture tour and in the following year was elected to a professorship of modern English literature at Princeton university, which he resigned in 1923.

Noyes's most considerable achievement was the epic trilogy, *The Torch-Bearers* (three volumes, 1922–30), which took as its theme the progress of science through the ages. In addition to several volumes of poetry—his *Collected Poems* appeared in 1910, 1920, 1927 and 1950—he wrote critical essays, biographies and novels. After his conversion to Roman Catholicism in 1927 his religious beliefs tended to colour his work, in particular *The Unknown God* (1934) and *Voltaire* (1936). Among his later publications were *Two Worlds for Memory* (1953), an autobiography, and *The Accusing Ghost* (1957), a defense of Roger Casement. Noyes died at Ryde, Isle of Wight, on June 28, 1958.

NOYON, a city of northern France in the *département* of Oise, is built at the foot and on the slopes of a hill 67 mi. (109 km.) N.N.E. of Paris by rail. Pop. (1962) 9,019. Its beautiful transitional Romanesque-Gothic cathedral (12th–13th century) and the old *hôtel de ville* were burned during World War I and later restored. The cathedral treasures include a Carolingian manuscript and a rare musical incunabulum. The town has good trade in livestock and grain and contains chemical and artificial manure works and iron foundries.

Noyon, the ancient Noviomagus Veromanduorum, was Christianized by St. Quentin at the end of the 3rd century, and about 530 the seat of the bishop was transferred there from St. Quentin. St. Eligius was bishop in the 7th century. Charlemagne was crowned there in 768 and Hugh Capet crowned in 987. Till the French Revolution the bishopric was one of the ecclesiastical peerages of the kingdom. At the beginning of the 12th century Noyon obtained a communal charter through the favour of its bishops. It was ravaged by the English and the Burgundians during the Hundred Years' War. It was captured by the Spaniards in 1552, and then by the Leaguers, who were expelled in 1594 by Henry IV. John Calvin was born there in 1509 and the house in which he lived as a boy is now a museum. Noyon was occupied by the German army in 1914 and was abandoned, bombarded and reduced to ruins, 1917–18. In World War II the town was again occupied by the Germans (June 1940) and was severely damaged.

NSAW, a West African people known also as Banso, numbering about 52,000 (1960s), the largest of the Tikar groups in Bamenda district of Cameroon Republic. Their kingdom, with its capital at Kimbaw (or Kumbo), is ruled by the *Fon* ("king," pl. *Afon*), whose position is hereditary within one of their exogamous patrilineal lineages. The queen mother (*Ya*, pl. *Aya*) assists in the government and in the hearing of court cases.

The Nsaw practise sedentary farming with fallowing. Maize is the principal crop, supplemented by taro, yams, a white carrot (*Coleus*), white and sweet potatoes, cassava, Guinea corn (*Sorghum*), finger millet (*Eleusine*), plantains, beans, peas and other fruits and vegetables. Farming is done largely by women, with a short-handled hoe as the main tool. Men clear the high bush, help in harvesting grain crops, hunt, gather honey, raise plantains, tobacco, chickens and goats, provide fire wood and are responsible for house building and thatching. Women trade in local produce, and men make long trading journeys. Some men do wood carving, make baskets or raffia hats, tap palm wine and engage in new crafts such as carpentry, tailoring and brickmaking. Pottery and iron tools are obtained in trade from neighbouring peoples, and cotton cloth from the Hausa of northern Nigeria. European clothing has been adopted by a few, but men generally wear loincloths woven by the Hausa, and women wear string fringes. Islam has been introduced through the Hausa and Fulani (*qq.v.*), but it is estimated that over 80% of the Nsaw follow their traditional religion. They believe in a supreme god who created human beings and is associated with the earth and its fertility. Ancestors are worshiped as intermediaries between god and the living. Diviners consult the black spider (*ngam*), as among the Bamum.

See P. M. Kaberry, *Women of the Grassfields* (1952). (Wi. B.)

NUBA, the name commonly used to describe the Negroid inhabitants of the Nuba hills in the southern half of Kordofan (*q.v.*) province, Republic of the Sudan. This region (approximately 30,000 sq.mi.) is studded with rugged granite hills which rise sharply from a wide clay plain and vary considerably in size and extent.

The Nuba peoples (numbering more than 500,000 in the 1960s) live on or near the hills (the plains being mainly occupied by Baggara Arabs) in many tribal groups that differ in physical type, language and culture. They are vigorous, independent hill folk of good physique, strong in traditions and fighting qualities. The number of language groups (ten) is fewer than formerly supposed: Tegali-Tagoi; Koalib-Moro; Talodi-Masakin; Lafofa; Kadugli-Krongo; Katla; Temein; Nyimang; Daju; "Hill" Nubian (Dilling, Ghulfan, etc.) Researches indicate possibilities of reducing these. The first four have sometimes been termed Bantoid, as they share a noun-class system reminiscent of Bantu. The speakers of Daju and "Hill" Nubian are incomers from the west and north respectively.

S. F. Nadel gives a fourfold cultural grouping based on kinship structure, type of clan organization and the presence or absence of a spirit-possession cult practised by mediums (*kujurs*). Kinship descent is, broadly speaking, matrilineal in the south, patrilineal elsewhere. The Nuba are agriculturalists (using spade-type hoes), with hill terraces and, now, larger cultivations on the plains. The main crops are millet, sesame, maize, peanuts, beans, onions, cotton and tobacco. They also keep cattle, sheep, goats, donkeys, fowl and (except in Islamized areas) pigs. Religious practices are much linked with agricultural rituals, animal sacrifices are made to ancestral spirits and priestly experts and rainmakers have an important position.

Tribal units are under government-appointed *meks* or chiefs and patterns of homestead vary. Marriage payments are in livestock, weapons and other objects, and by agricultural service. In the remoter hills, men still go naked and women wear beads and lip-plugs, but clothes are increasingly worn. In some parts the lower incisors are removed in both sexes; male circumcision is now more widely practised. Wrestling and stick fighting are the principal sports. Varying degrees of Islamization may be observed and Arabic is used as the *lingua franca*.

Tucker and M. A. Bryan, *The Non-Bantu Languages of North-Eastern Africa*, with bibliography (1956); W. MacGaffey, "History of Negro Migrations in the Northern Sudan," *Southwestern Journal of Anthropology*, vol. 17 (1961). (R. C. St.)

NUBAR PASHA (Nubar Pasha Nubarian) (1825–1899) was one of the outstanding Egyptian statesmen of the 19th century. Born at Smyrna (Izmir), Turk., in Jan. 1825 of an Armenian Orthodox family originally from Shikakhokh in the southeast of Russian Armenia, he was educated at Geneva, Switz., and Sorèze, France. In 1842 he went to Egypt as secretary to his uncle, Boghos Bey Yusufian, Mohammed Ali Pasha's director of foreign affairs. On Boghos Bey's death in 1844 Nubar became secretary-translator to Mohammed Ali and later joined the staff of Ibrahim Pasha whom he accompanied to Paris in 1846 and 1847. Abbas I who succeeded as viceroy in 1848, made Nubar his first secretary. In 1853 he was appointed viceroy's agent in Europe, returning to Egypt after the accession of Said Pasha with whom he traveled to the Sudan in the winter of 1856–57.

Nubar's promotion was now rapid. A member of the railway board, and from 1858 director of railways, he took a leading part in the arrangements between Said and Ferdinand de Lesseps for the construction of the Suez canal, and when Ismail Pasha became viceroy, he went to Paris in 1863–64 to negotiate with the French government and the Suez Canal company a revision of the original contract. In 1865 he was minister of public works and from 1866 minister of foreign affairs. Nubar's ability as a negotiator is nowhere better shown than in his eight years of bargaining with the powers and the Porte which ended in 1876 in the reform of the consular courts and the institution of mixed tribunals. (*See* Capitulations.) Ismail's debts were bringing him to the verge of bankruptcy and in Aug. 1878, under pressure from Britain and France acting on behalf of Ismail's creditors, the khedive reluctantly appointed a mixed Egyptian and European ministry led by Nubar, who also retained the portfolios of foreign affairs and justice.

Nubar vainly tried to induce Ismail to adopt the role of constitutional ruler and was criticized in Egypt for his apparent sympathy with the bondholders. In defiance of the powers, Ismail dismissed his ministry in April 1879 and within three months was himself deposed. His successor, Mohammed Tewfik Pasha, recalled Nubar to the presidency of the council of ministers in 1884 on the resignation of the ministry of Mohammed Sharif Pasha. Nubar remained in office until 1888 when he resigned after a clash with Sir Evelyn Baring, the future earl of Cromer, British representative in Egypt. In 1894 Nubar became prime minister for the third and last time, but ill health coupled with impatience under British tutelage soon caused his resignation (1895). He retired to Paris where he died on Jan. 14, 1899.

Two of his relatives achieved distinction in the khedivial service; his brother, Arakel Bey al-Armani, governor of Khartoum (d. 1858), and his nephew, Arakel Bey Abro, governor of Massawa, killed in 1875 in the Egyptian-Ethiopian war.

Nubar's brilliant, if somewhat doctrinaire, mind fitted him preeminently for international negotiation rather than for practical administration. Combining Ottoman with European culture and sharing the Turkish-speaking Egyptian ruling families' contemptuous ignorance of Arabic, he had little in common with Egyptian nationalists whom he regarded as provincials, while they, notwithstanding his great services for Egypt, regarded him as a foreigner.

L. Hi.)

NUBIA, an ancient region of northeastern Africa, extending approximately from the Nile valley at Aswan, near the First cataract in upper Egypt, eastward to the Red sea, westward to the Libyan desert and southward to about Khartoum, in the Republic of the Sudan. Its north-south extent is about 560 mi. between latitudes 16° and 24° N., and most of it lies in the Sudan. It has no strictly defined limits, however, and is little more than a geographical expression. It was originally called Cush (Kush) under the Pharaohs and the Greeks called it Ethiopia (*see* Ethiopia, Ancient); the present name is derived from *nob* (slave) in the Mahass dialect of the Nubian language, of which four different dialects are spoken between Aswan in Egypt and Dongola in the Sudan.

The country consists mainly of sandy desert and rugged plateaus

of the Nubian sandstone through which the Nile flows in a gorge. The river in this section is narrow with little or no flood plain, but a continuous series of slight falls and rapids occurs, coincident with outcrops of harder crystalline rock. Between Khartoum and Philae, Egypt, the Nile makes a great S-shaped bend; the region west and south of the Nile within the first bend is the Bayuda desert (Sahra' Bayyudah) and that east of the Nile the Nubian desert, corresponding roughly with the conventional division of upper and lower Nubia. Most of Nubia is within the almost rainless zone.

The construction of the Aswan high dam in Egypt, and the consequent ponding back of the Nile creates a narrow lake extending about 350 mi. south, submerging not only Wadi Halfa, the only settlement of any size in the region, but also a number of discontinuous patches of cultivated land. This necessitated the resettlement of about 60,000 peasant cultivators. For the measures taken to preserve ancient monuments *see* section below, *Excavation and Preservation of Nubia's Sites and Monuments*. The communications between Egypt and the Sudan also needed replanning; they were formerly maintained by steamer service between Ash Shallal (near Aswan), the terminus of the Egyptian railway, and Wadi Halfa, the northern terminus of the Sudanese railways.

(A. B. M.)

ARCHAEOLOGY AND EARLY HISTORY

In Nubia the early Stone Age ran its usual course. Pre-Abbevillian tools occur at Wadi Halfa and at Nuri below the Fourth cataract. Abbevillian tools were found at Wadi Halfa, between the Second and Third cataracts at Sai Island (Jazirat Say) and Wawa, in Wadi al Hudi near the mouth of the Atbara river and near Omdurman. Acheulean tools occur near Wadi Halfa, at Laqiyah in the Wadi al Qa'b and at Omdurman. Early Levallois occurs near Tangasi between the Third and Fourth cataracts; and Acheulean-Levallois hybrid cultures near Wadi Halfa, at Salimah oasis, north of 'Abri and, in the Sangoan (Tumbian) form, at Omdurman.

The Levalloisian technique lasted long. It is seen in the Sebilian culture from Kom Ombo (Kawm Umbu) and in surface finds all over Nubia; and it still affected cultures at the beginning of the historic period.

Fossils have been found associated with the Sebilian at Wadi Halfa. In the Upper Sebilian, microliths become dominant, suggesting the Capsian culture from north Africa with its backed-blade technique. Similar microliths are widely found on the surface; and at Khartoum a culture with Capsian connections and indistinguishable from the Wilton of southern Africa occurs with bone harpoons with four or more barbs, barbed bone arrowheads and redware pottery bowls decorated with wavy-line impressions made by a catfish spine. The makers were Negroes who lived by hunting and fishing. They had no domestic animals and did not cultivate. This culture has been found as far north as the Fourth cataract and between Wadi Howar in the west and Kassala in the east.

It was followed between Jabal al Awliya and the Second cataract by one in which gouges, celts and amazon stone beads, all typical of the Fayyum Neolithic, occur with pottery, most of which is burnished and the most typical of which is a hard redware decorated with triangular impressions in a pattern imitating basketwork. This pattern developed out of the wavy-line pottery of Early Khartoum. Early forms of black and black-topped redware occur; and shards burnished after combing or incision show how easily rippled ware could have developed. With this Khartoum Neolithic culture occur zeolite lip plugs, notched fish-hooks of shell and bone harpoons, most of which have four or more barbs and a perforated butt. The next culture so far known is one with ripples made by pebble-burnishing over combing. One such pot found at Omdurman is identical in all but size with one from the A-group cemetery at Faras near Wadi Halfa, which has been dated to the reigns of Zer and Zet (about 3000 B.C.) by pottery and copper tools imported from Egypt. At Omdurman about 18 pots were buried in each grave. Gourd shapes and small deep bowls were common. Large deep bowls of coarse redware decorated with squares alternately plain or hatched by impressions made by catfish spines show connections with both Early Khartoum and the Gerzean periods of Egypt.

Egyptian Influence.—Rock pictures are frequent along the Nile between the First and Third cataracts, and while no doubt a few representing wild animals date from the prehistoric period, all historic periods are represented. Sites of the earlier Egyptian predynastic have not been found south of Ad Dakkah. There is on a rock near the Second cataract a reference to the conquest of lower Nubia by Zer, third king of the 1st dynasty, and Egyptian imports dating from his and the succeeding reign were found in the neighbouring A-group cemetery of Faras. Lack of sites in Nubia associated with the Old Kingdom may be because of the activities of those Pharaohs: the earliest historic reference to Nubia is to a raid by Sneferu (*c.* 2613 B.C.) who built ships and "hacked up" the land of the Nehesi or Nehsui (*cf.* modern Al Mahas) and brought back many prisoners and cattle; it is probable that such raids devastated a land in which civilization had flourished during the Neolithic and predynastic periods. Under the 5th and 6th dynasties (*c.* 2494–*c.* 2181 B.C.) Egypt's contact with the south became rather more peaceful. Although under Pepi I military expeditions had been led by Uni to the Nehes lands of Irthet (Irtjet), Medju (Medjai, *cf.* modern Beja), Yam, Wawat, Kau and the land of Temeh, nevertheless Harkhuf of Elephantine made four trading expeditions during the reigns of Merenre and Pepi II, as far as Yam (Darfur?), returning with donkeys laden with incense, ebony, leopard skins and ivory.

After the fall of the Old Kingdom a cattle-owning people (the C-group) came into the area between the First and Second cataracts and survived until the beginning of the 18th dynasty. They lived on the riverbank in settlements of round huts of wood and grass and buried their dead beneath mounds of earth protected by circular walls of dry stone. They wore leather clothing, and bowls of black or brown ware, decorated with elaborate incised patterns often filled with white and later with coloured pigments, are characteristic of their pottery. Under the 11th dynasty Egypt turned its attention to the south again. An inscription near Aswan records the dispatch of ships to Wawat.

The first Pharaohs of the 12th dynasty, Amenemhet I and Sesostris (Senusret) I, occupied Nubia as far as Semna, about 50 mi. S. of the Second cataract. Communications with Egypt were protected by massive mud-brick forts, a fine example of which at Buhen opposite Wadi Halfa was excavated by W. B. Emery in the 1960s. A trading post was built probably in the reign of Amenemhet II (1929–1895 B.C.) at Karmah (Kerma) at the downstream end of the Dongola reach and 150 mi. S. of Semna. Karmah was probably the home of the chief of Cush: in graves excavated locally the principal occupant was laid in native fashion on a bed in a large low tumulus, while women and retainers, sometimes numbering hundreds, were buried alive with him. It is in any case most unlikely that G. A. Reisner, the Egyptologist, was correct in thinking that it was the headquarters of successive Egyptian governors. The Egyptian statues found in these graves were presumably traded to the princes of Cush by Egyptian merchants during the Second Intermediate period (*c.* 1720–1567 B.C.). They At Karmah Egyptian craftsmen developed local industries. They made exquisitely fine burnished black-topped red pottery never again equaled, objects in faience and quartz decorated with blue glaze and short copper swords with ivory hilts.

The southern group of Egyptian forts (Mirgissah, Shalfak, Uronarti and Semna) were probably built by Sesostris III (1878–43 B.C.) after a local rising. Until the 13th dynasty the level of the Nile flood was recorded at the Semna forts. These levels show that the Nile was 26 ft. higher in flood than it now is, and the rainfall must have been correspondingly greater to provide grazing for the C-group cattle and to allow tribes to live on the west bank in what is now desert.

At some period subsequent to this, and probably connected with the expulsion of the Hyksos from Egypt, these forts were all destroyed by fire. Shards of C-group and Pan-grave pottery and stone axes copying bronze axes typical of the 17th dynasty have been found as far east as Agordat in Eritrea.

Ahmose I, the founder of the 18th dynasty, began the reoccupation of Nubia and built a temple at Buhen; and his successor Thutmose (Tuthmosis) I occupied the whole of Cush at least as far as 50 mi. S. of Abu Hamad, where he set up a boundary inscription. Cush was then incorporated in Egypt under a viceroy, whose first duty was to dispatch the tribute of Nubia to Egypt. Informative representations of the arrival of this tribute in Egypt may be seen in tomb and temple at Luxor. Almost every Pharaoh founded a town or built one or more temples in Nubia from the local sandstone. The most splendid was that at Sulb (Soleb) dedicated to Amon and himself by Amenhotep III, who also built a smaller one at Seddenga for the worship of his queen Tiy. Other temples include those built by Queen Hatshepsut at Buhen, Thutmose IV at Barkal, Amenhotep IV (Ikhnaton) at Sesibi and Tutankhamen at Faras and Ḳawa.

The construction of temples was continued under the 19th dynasty. Ramses II (1304–1237 B.C.) built two great rock-hewn temples to himself and his queen, Nefertari, at Abu Simbel, and also temples or shrines at Gerf Husein (Jurf Husayn), Bayt al Wali, Wadi Sabu'a, Dirr (Dayr al Bahri), Ibrim, Faras and 'Akasha in lower Nubia; and his name occurs at Amarah West, Sais, Kawa and Jabal Barkal in upper Nubia. In places, as at Kawa, he was not above erasing the name of the original builder and substituting his own. Seti I built the town wall at Amarah West and probably built the original temple, to which various kings up to Ramses IX made additions. The known antiquities of Nubia under the New Kingdom or Empire are entirely Egyptian. They include at Anibah tombs built with pyramidal roofs like those at Dayr al Madinah; and farther south inscriptions at Tangur (Shuqayq), Dosha, Nauri, Tumbus and Kurgus.

Napata and Meroe.—From the period between 1100 and 750 B.C. nothing is known. Napata (*q.v.*) seems to have been still Egyptianized when in 750 B.C. Kashta set himself up there as king of Cush and conquered upper Egypt, founding the 25th dynasty, known as the Cushite dynasty. Piankhi (*c.* 730 B.C.) included the rest of Egypt in his empire, and Shabaka, his successor, transferred the capital to Thebes and was known as king of Cush and Egypt. Piankhi built the great temple of Amon at Napata. The only monuments of Shabaka and Shebitku (Shabataka) in Nubia were their pyramids at Kurru. All the pyramids in this cemetery are now ruined, but the painted chambers of Tanutamon and his sister Kalhata are preserved. The burial chamber was excavated in rock below ground level, approached from the east by a stairway cut in the rock. The pyramid was built on ground level above the chamber and had a small mortuary chapel on its eastern face. (These chapels have all disappeared at Kurru and Nuri, but some of those at Meroe remain, and the designs with which they are decorated are of considerable interest and importance.) Taharqa built more than one temple at Napata, carved four colossal figures out of the face of Jabal Barkal and built the largest pyramid of a new cemetery at Nuri. A disastrous clash with the Assyrians, who were armed with iron weapons and had recently included Palestine in their empire, led to the evacuation of Egypt by Taharqa. His successor, Tanutamon, temporarily reoccupied upper Egypt, but was soon forced to abandon it (661 B.C.). The dynasty, however, continued to reign, first at Napata and subsequently at Meroe (*q.v.*), for about 1,000 years. The immediate successors of Tanutamon (Atlanersa, Senkamanisken, Anlaman, Aspelta, Amtalka and Malenakan, *c.* 653–538 B.C.) were able to construct pyramids and temples in the pure Egyptian style. A temple at Jabal Barkal was begun by Atlanersa and finished by Senkamanisken. The sun temple at Meroe (mentioned by Herodotus) was built by Aspelta; and the temple of Amon at Meroe was apparently built by Aspelta, Amtalka and Malenakan.

The kingdom no doubt stretched as far as Sennar, where a scarab of Shabaka has been found, and Jabal Mayyah, where objects dating from Taharqa to Aspelta and later periods were discovered; and it is reasonable to suppose that from Sennar it extended to the gold country of Beni Shangul (Ethiopia), and from Jabal Mayyah to the Shilluk country on the upper White Nile.

Napata was sacked *c.* 590 B.C. by an expedition sent by the Saite Psamtik II to forestall a Cushite threat to reestablish their dominion over Egypt. Greek and Carian mercenaries, who took part, left graffiti at Abu Simbel and Buhen. This sack of Napata led to the transfer of the political capital to Meroe, although kings were buried at Napata as the old religious capital up to the time of Nastasen (*c.* 315 B.C.). The Persians are said to have invaded Nubia under Cambyses in 522 B.C., but of this there is no evidence, although Nubians with carnelian-tipped arrows served in the army of Xerxes.

From his study of the royal cemeteries of Napata and Meroe, Reisner constructed a king list covering this period. Twenty kings and some of their queens were buried at Nuri, and all their names have been recovered. Forty-one rulers, who succeeded them, of whom 23 have been identified (4 or 5 were queens), were buried from *c.* 300 B.C. in pyramids at Meroe. Reisner thought that during this later period there were two occasions when Napata was for a time independent of Meroe and its rulers buried in the two groups of pyramids at Jabal Barkal. But there is some doubt about this, although the names of four kings did turn up at Kawa that were not found at Meroe. Ergamenes (248–220 B.C.) built the temple of Dakkah and imported an Egyptian scribe to decorate his tomb chapel. He and his successors (who built six large pyramids) represent the most prosperous period of Meroe, when relations with Ptolemaic Egypt were friendly. But, cut off from Egypt, the Egyptian culture of the kingdom naturally degenerated. The Meroitic cursive script was invented before 200 B.C. When it was in general use, the knowledge of Egyptian and Egyptian scripts was quickly lost. Soon after 150 B.C. the Meroitic hieroglyphic script was invented for decorative inscriptions. The traditional offering scenes, which occur on the older pyramids, were then varied, giving them a distinctive Meroitic tinge. Degeneration was continuous until 45 B.C., when Queen Amanishakhete came to the throne. In 23 B.C. Gaius Petronius had invaded Napata with a Roman army as a result of frontier trouble in lower Nubia, when the statue of Augustus had been looted from Syene (modern Aswan). He destroyed Napata and, retiring, left a garrison at Ibrim. Queen Amanishakhete is buried in the second largest pyramid, in which Giuseppe Ferlini found a hoard of treasure. Her successors, King Natakamani and Queen Amanitere (15 B.C.–A.D. 15), repaired the temple of Amon at Meroe, built two temples at Naqah, a temple at Wad Ban Naqah and one at 'Amara East—the last two disappeared during the 19th century—and restored the great temple of Amon at Napata. The colossal royal statues on the temple site on Argo Island probably belong to this period. From that date degeneration was unchecked. The pyramids gradually became smaller and red brick eventually replaced stone in their construction. Red brick was much used for building in the latter centuries at Meroe, and in the last palace it was used in a crude imitation of a Roman bath.

Nubia entered the Iron Age during the Meroitic period. A few manufactured iron objects were imported in the 6th century B.C., but by 480 B.C. Nubia was still practically without iron. Pyramid foundation deposits first include iron about 360 B.C., when it probably began to be smelted at Meroe, although remaining a royal monopoly for several centuries. Meroitic pottery at Faras was predominantly wheel-made with some elaborate painted designs in the 2nd century A.D. To the same date belong fine ware, with repeated impressions of small stamps with designs such as the ankh, and imported barbotine cups. Handmade pottery including black ware with impressed designs filled with red or yellow pigment also occurred and was probably more frequent in the south. Artificial reservoirs in the island of Meroe, some of them associated with small temples (as at Al Musawwarat, as Safra, Naqah, Hardan, Awateib, Basa, Duanib and Umm Usuda), and in the Gezira were a feature of the Meroitic period and suggest decreasing rainfall.

The last record of the kings of Meroe is a demotic inscription from Philae recording an embassy of King Tekerideamani in A.D. 253. The knowledge of writing died out. There are no inscriptions on the walled group of temples at Al Musawwarat. The Blemmyes of the Eastern or Arabian desert (Beja) destroyed the Meroitic culture in lower Nubia; and Meroe itself was destroyed between A.D. 320 and 350 by an expedition dispatched by Aeizanes,

king of Aksum, to crush a trade rival or by one of his predecessors.

The Nobatae.—The Meroitic culture is followed in Nubia by one attributed by Reisner to the X-group. These may have been the Nobatae, a name possibly derived from confusion between Nuba and Napata (the "Red Nuba" of Aeizanes). They replace the northern kingdom of Napata, which had twice made itself independent of Meroe. The X-group tumulus is a direct descendant of the Meroitic pyramid, and X-group pottery is in the Meroitic tradition. X-group cemeteries occur at Napata (Az Zumah and Tangasi) and at Wawa, Sai Island, Firqah, Attiri, Gemai, Adindan, Ballanah, Kustul, Ibrim and Kalabsha (Kalabisheh). The royal cemeteries at Ballanah and Kustul covered two centuries. The kings were buried with Meroitic insignia, and human beings and animals were sacrificed to accompany them. Grave goods included imported Byzantine objects; but no evidence of a written language was found. In the Meroe area, graves contemporary with the X-group contain many large handmade mat-impressed pots and smaller bowls burnished and decorated with incisions near the rim. Large mound graves of this period are common as far south as Khartoum. The X-group have also been identified with the Blemmyes, who from the 3rd century had continually troubled Egypt and by the 5th century were established at Talmis (Kalabsha), combining with the Nobatae to raid upper Egypt. They were compelled by Florus in A.D. 452 to keep the peace but were allowed to visit the temple of Philae and to borrow the statue of Isis.

About A.D. 540 the Nobatae were converted to Christianity, and shortly after that, at Kalabsha, their king Silko, then a Christian, records his defeat of the Blemmyes and of the upper Nobatae (of Napata?). After this the capital of the Nobatae seems to have been at Pachoras (Faras), until they were amalgamated with Mukurra (Muqarra) in the single Christian kingdom of Dongola (*q.v.*). South of that was the kingdom of Alwa or Alodia (Aloa) with its capital at Soba (Sawba) near Khartoum. Alwa had become Christian in A.D. 580.

Muslim Conquest.—In A.D. 652 a Muslim army from Egypt captured Dongola and compelled the kingdom to pay tribute to Egypt. Arab historians often mention relations between Egypt and Nubia; but the kingdom of Dongola remained Christian until the 14th century, when it was overrun by Mameluke armies from Egypt. The stone castles of Nubia (Sai, Khandaq, Bakhit, etc.), which show crusader influence, date from the unsettled period before the final fall of Dongola. Soba survived for another two centuries, and then gave place to the Muslim Fung (Funj) kingdom of Sennar.

Christian Influence.—The churches of Nubia were small when not adaptations of heathen temples. Some were built of stone masonry, but brickwork was commoner. In the north there were two principal types, basilican and domed, and mud brick was usual; whereas in Dongola a typical church had red brick walls with a roof supported by four granite monolith columns with separate granite capitals. Mural paintings covered the walls. Little now remains of any of these churches except one or two small mud-brick buildings in out-of-the-way places (*e.g.*, the church of Abdelgadir near Wadi Halfa), and the ugly atypical fortified church at Old Dongola, which owes its preservation to its conversion to a mosque in the 14th century. In Dongola during the Christian period, graves frequently had a rectangular stone superstructure with tombstones inscribed with Greek letters and either Greek or Coptic inscriptions; and circular stone cairn graves of the same period also occur as far south as Khartoum and west across northern Kordofan. Rare inscriptions of Old Nubian in Greek characters have also been found. Pottery in the Meroitic tradition continued in the Christian period, the best being a thin ware coated with a white slip and decorated with designs in sepia. For the later history of Nubia *see* the history sections of EGYPT and SUDAN, REPUBLIC OF THE. (A. J. AL.)

Excavation and Preservation of Nubia's Sites and Monuments.—At the beginning of 1960 the governments of the United Arab Republic (U.A.R.) and the Sudan turned to the United Nations Educational, Scientific and Cultural organization for help in salvaging the ancient sites and monuments of Nubia threatened with destruction by the great lake which would build up behind Egypt's new dam at Aswan. UNESCO responded by launching what subsequently grew into the biggest archaeological rescue operation of all time.

Field Expeditions.—About 300 mi. of Nubia along the banks of the Nile in Egypt and the Sudan became the scene of intense activity of some 24 expeditions from as many countries. Before 1960 that part of Nubia inside the Sudan was virtually terra incognita and its archaeological richness may be measured by the number of hitherto unknown sites later revealed—more than 200 along a 25-mi.-stretch of the river's banks. They ranged from prehistoric, through A-group and C-group to Pharaonic, Meroitic, X-group and Christian, apart from rock inscriptions.

Necessary preliminaries to operations were the aerial archaeological surveys carried out by UNESCO in collaboration with the governments of the U.A.R. and the Sudan in 1960. The UNESCO mission in Sudanese Nubia continued to assist the national expeditions by making available survey data and a well-equipped photographic laboratory at Wadi Halfa. The mission in addition made a ground survey of the west bank and the many islands of the Second cataract and dug a large number of sites. An important discovery by one of the national expeditions was that of an Egyptian Old Kingdom town devoted to copper smelting, at Buhen, evidence of much earlier Egyptian penetration of Cush than was previously believed.

The 12th-dynasty fortresses of the Second cataract received well-merited attention. Built of mud brick, they could not be salvaged. That at Buhen, including the town of the same period, was completely cleared and much valuable data on early Egyptian military architecture was gathered. Mirgissah fortress was also the scene of remarkable finds. In the sandy plain below the fortress was found a large complex of fortifications enclosing buildings well preserved; all dated from the 12th dynasty. Nearby was uncovered a necropolis of the Kerma (Karmah) culture and an important cache of Middle Kingdom execration texts.

Several expeditions uncovered rich remains of the C-group people, in the shape of many cemeteries and even houses, and much was added to the somewhat scanty knowledge of this historically significant culture. Cemeteries of the A-group were located and prehistorians found ample evidence that Nubia was well populated in Paleolithic times. Other teams recorded the many rock drawings and inscriptions discovered in Nubia. X-group cemeteries were dug by most of the expeditions, the outstanding find being at Kasr Ibrim. There two large tomb magazines, unrobbed, yielded a splendid array of bronze vessels, glassware, ornaments and iron weapons.

Evidence of the early Christian occupation of Nubia was found in profusion. Settlements, each with its church, were uncovered on 13 islands of the Second cataract alone. On the surrounding mainland, every slope and promontory bore signs of once thriving communities. A spectacular find was made in the great basilica hidden beneath the mound at Faras West (Pachoras) where the excavators removed over 100 magnificent frescoes in a remarkable state of preservation. The walls of the church bore not only religious paintings but inscriptions in Greek and Coptic, including a valuable list of the bishops of Pachoras, some of whose tombs and funerary stelae were found.

Temples.—To save the temples of Nubia was a financial problem and the raising of funds was the main concern of UNESCO's International Campaign Executive committee. Several states co-operated fully by undertaking to defray the cost of transferring certain temples out of reach of the rising waters. As examples, the Federal Republic of Germany completed the removal of the large Egypto-Roman temple of Kalabsha to a point about 30 mi. away; the U.S. government undertook to conserve the group of Ptolemaic Roman temples on the island of Philae, which, being located below the new dam, fortunately did not have to be removed; the French government undertook the transfer of the temple of 'Amada, while several other temples of Egyptian Nubia, namely Qertassi (Kertassi), Taffeh, Dakkah, Muharraqah and Debod (Debot) were dismantled by the U.A.R. for later re-erection. In all, about [illegible] temples and shrines were to be preserved.

In Sudanese Nubia, Hatshepsut's temple at Buhen was dismantled by the Egypt Exploration society of the United Kingdom. The removal of this temple exposed for the first time in 3,500 years the original Middle Kingdom temple beneath. The two New Kingdom temples at Semna were also to be removed.

Much more difficult problems were posed in the salvaging of the two rock-cut temples of Ramses II and Queen Nefertari at Abu Simbel (*q.v.*). The plan (evolved by Swedish experts) was to remove the top of the sandstone cliff above them, dissect the temples in the interior and reassemble them on prepared sites on the plateau above. A temporary coffer-dam would hold back the rising waters while the work was in progress. It was a stupendous task and the estimated cost was high. Nevertheless there did seem to be a good prospect that these two superb reminders of a great civilization would be saved for posterity.

Meanwhile, not only Abu Simbel but all the temples and shrines in Egyptian Nubia were recorded by epigraphists and by photogrammetric photography undertaken by teams from the Documentation and Study Centre for the History of the Art and Civilisation of Ancient Egypt, established at Cairo by UNESCO and the government of the United Arab Republic. NUBIAN DESERT, covering about 90,000 sq.mi. in northeastern Sudan, is the eastern extension of the Western or Baiyuda desert (Sahra' Bayyudah) and Libyan desert (*q.v.*) beyond the Nile valley and the southern extension of the Arabian desert (*q.v.*). It occupies the area west of the Red sea between the Itbay ('Atbay) mountains and the Nile in its course from the Sixth cataract (above Atbara) to the Second cataract (near Wadi Halfa). Generally the desert is without water, vegetation or people, though limited settlement occurs along some of the eastern wadis, notably the Ibib. (R. W. SL.)

NUBIAN LANGUAGE AND WRITING. Nubian is the name given to the language of the Barabra or Nubians in the Nile valley, between Merawi, a few miles below the ancient Napata, and the First cataract at Aswan. It has two principal dialects: the Mahass-Fadija being spoken in the central portion, from a little south of the Third cataract, and the Dongola-Kenuzi at both ends of the region.

Languages related rather closely to Nubian of the Nile valley are spoken in the hills of Kordofan and as far westward as eastern Darfur. This entire area is considerably south and west of the portion of the Nile valley in which Nubian is spoken and probably represents the point of origin of Nile Nubian. The entire Nubian group belongs to the Macro-Sudanic family of languages spoken in east and central Africa. (*See* AFRICAN LANGUAGES.)

The speakers of Nile Nubian are at present Muslims and their language is penetrated with Arabic borrowings. During the medieval period, however, they were Christians and the Nubian Church was affiliated with the Coptic Church of Egypt with its patriarch in Alexandria. These Nubians adapted the alphabet of the Egyptian Copts, in turn derived from the Greek alphabet, to their own language. The documents, which are generally of a religious character and translated from the Greek, are of great linguistic interest as representing the only language at present spoken by Negroes from which indigenous records antedating the modern period are to be found. The language appears to be directly ancestral to the modern dialect of Mahass-Fadija. The writings date from the end of the 8th century to the beginning of the 14th century.

ÑUBLE, a province of central Chile, includes segments of coastal range, central valley and cordillera. Area 5,387 sq.mi., pop. (1960) 284,516. Ñuble, formed in 1848, was altered significantly in area in 1927 when Itata department was transferred from Maule province (*q.v.*). Chillán, founded in 1580, is the provincial capital; pop. (1960) 66,771. Together with San Carlos (13,598), Bulnes (5,831), Yungay (2,116) and Quirihue (10,203), it is a departmental seat.

The provincial economy is stimulated by the Chillán plan, a comprehensive rural improvement program operated by Chilean and U.S. agronomists. The vine, wheat, edible legumes, fruit and livestock are important. Industry, chiefly in Chillán, is concerned with food processing, milling (grain and lumber), tanning and shoe manufacturing. The city's recovery from the catastrophic 1939 earthquake is advanced; new public buildings and the cathedral are striking. Chillán's open-air market is perhaps the most colourful in Chile. The state railway, which traverses the centre of the province, has branches that lead to Tomé and Concepción and into the cordillera. Minor beach resorts, the cordilleran spa of Termas de Chillán and ski lodges near Chillán volcano are recreation areas. Chillán Viejo (6,058) is the birthplace of Bernardo O'Higgins and Ninhue is the birthplace of Arturo Prat, Chile's most celebrated naval hero. (J. T.)

NUCLEAR ENGINEERING is concerned primarily with the design, construction and operation of nuclear reactors. It became clear during the 1950s that substantial numbers of specially trained engineers are needed for the development of nuclear power and its associated industries. The working methods of nuclear engineering are derived from physics and the older engineering fields, but special techniques have had to be developed to solve the unique problems encountered in dealing with nuclear fission, and many of these are surveyed in this article.

Nuclear reactors based on the fusion of light elements are envisaged, but they are not considered here because many problems in the field of physics must be solved before such reactors can become practical power producers.

The physical principles of nuclear fission are discussed in the articles ATOM; ATOMIC ENERGY; and NUCLEUS. This article consists of the following sections:

VII. Fuels and Fuel Recovery
VIII. Economics of Nuclear Power Production
IX. Other Industrial Applications

I. INTRODUCTION

Nuclear reactors are devices which yield large amounts of heat and radiation and whose existence depends upon the availability of isotopes of heavy elements which undergo fission when struck by a neutron. The only isotope occurring in nature which is fissionable by slow neutrons is one particular isotope of uranium known as U^{235}. This is a rare isotope, since in natural uranium it is outnumbered approximately 140 to 1 by another isotope, U^{238}. When a single slow-moving neutron collides with an atom of U^{235}, the atom becomes suddenly so unstable that it may split violently into two major fragments accompanied on the average by two or three extra neutrons. There is a large release of energy, contained mostly in the kinetic energy of the fragments, which is quickly dissipated as heat. The energy release is so large by ordinary standards that the heat from the fissioning of all of the atoms of 1 lb. of U^{235} is as much as from burning 1,500 tons of coal.

Since neutrons are expelled in the fissioning process, it is possible for one fission to initiate another, and this another, and so on, thus creating a chain reaction. Basically, therefore, a nuclear reactor is designed to permit a self-sustaining and controlled nuclear chain reaction and to remove safely the heat which is generated.

Of the two to three neutrons that are released in each fission, at least one must be successful in producing another fission if the chain reaction is to persist. There are two main reasons why this is difficult to accomplish with natural or with only slightly enriched uranium. Instead of colliding with another of the widely spaced U^{235} atoms, the neutrons may escape from the uranium altogether, or they may strike and be absorbed by one of the U^{238} atoms. Although a fast neutron will occasionally cause fission of U^{238}, a chain reaction in natural uranium is impossible. This may be overcome either by increasing the proportion of U^{235} or by slowing down the neutrons. Uranium containing higher proportions of U^{235} is artificially produced in large gaseous diffusion plants. A gaseous compound of uranium is pumped through barriers containing very small openings, and since the lighter atoms of U^{235} have, on the average, slightly higher velocities than those of U^{238}, they slip through the barrier a bit more easily, thus increasing their concentration. Repeated often enough, the process yields uranium with almost any desired degree of enrichment in U^{235}. A reactor using such fuel and little other material is said to be a fast reactor because most neutrons are absorbed before they slow down. If the neutrons are slowed to a tiny fraction of their initial speed, they are much more likely to cause fissions of U^{235}, and it is then possible to sustain a chain reaction in natural uranium. The device for slowing the neutrons is called a moderator. The reactor in this instance is called a thermal reactor because most neutrons are slowed down to near thermal equilibrium with the moderator before absorption.

The moderator is either mixed with the uranium or, if the uranium is in the form of a latticework of solid fuel elements, the moderator occupies most of the intervening space. It must meet two primary requirements: first, it must be a very poor absorber of neutrons so that, when neutrons collide with its atoms, they are not lost; second, its atoms must be as small as possible—in other words, as near to the weight of the neutron as possible—so that the rapidly moving neutrons, through a series of "billiard ball" collisions, will lose almost all of their speed. The neutrons are then moving with small energies nearly in equilibrium with the average kinetic energy of the molecules of the moderator, and they are referred to as thermal neutrons.

A chain reaction, therefore, occurs if the neutrons released from any single fission bounce around often enough among the moderator atoms, without escaping or without being absorbed, and are slowed enough so that eventually at least one collides with another atom of U^{235} and causes it to undergo fission. When the number of neutrons moving in this manner in the reactor remains constant from one generation of fissions to the next, the reactor is said to be "critical." If, on the average, neutrons are being lost, the system is "subcritical," and the chain reaction will not sustain itself. If the density of neutrons is increasing, the system is "supercritical," and the rate of energy release will increase. Control of the reactor is accomplished by introducing materials which readily absorb neutrons, such as cadmium or boron. These may be in the form of control rods which can be withdrawn sufficiently for the reactor to become "critical."

The fission products (the fragments which result from fission in a reactor are a nuisance. There are about 40 different ways in which U^{235} may split, so that as the chain reaction proceeds, a variety of elements accumulate in the remaining uranium, most of them intensely radioactive—many of them strong absorbers of neutrons. To protect against this radiation and the radiation arising directly from fission, the reactor must be surrounded by thick, heavy shields. The gradual increase within the reactor in the amount of this neutron-absorbing material must be taken into account in the design of the control system.

Although U^{235} is the only easily fissionable material found in nature, it is fortunately possible to produce others. If nuclear energy depended solely on U^{235} fissions, it would be far less interesting as a new source of fuel for power generation. The more abundant atoms of U^{238} may become easily fissionable by converting them to isotopes of plutonium, Pu^{239}. This conversion may take place over a period of several days through a series of nuclear transformations when U^{238} absorbs a neutron. A nuclear reactor in which a chain reaction is being sustained may therefore, at the same time be producing new fissionable material. In fact, when it is possible for a second neutron from each fission to find its way into an atom of U^{238} and convert it to plutonium, thus renewing the supply of fissionable material at the same rate that it is being consumed, the energy available from natural uranium is multiplied theoretically by a factor of approximately 140. A reactor which accomplishes this is called a breeder the U^{238} in this instance is referred to as fertile material.

The production of plutonium, without attempting to utilize the energy release, was the specific purpose of the first big reactors ever built, located at Hanford Works, Wash. When these reactors were first put into operation their success seemed doubtful because the chain reaction tended to cease when the power level was increased. This was determined to result from the buildup of one particular fission product, an isotope of xenon, having an affinity for neutrons. The solution to this problem and the subsequent successful operation of the reactors was one of the exciting accomplishments of World War II.

Th^{232}, the predominant isotope of thorium found in nature, is also a fertile material, since a neutron absorbed in Th^{232} gives rise to a conversion to still another isotope of uranium, U^{233}, also easily fissionable. Thus, a reactor containing enough U^{235} to support a chain reaction and Th^{232} as a fertile material may also become a breeder.

In summary, therefore, a reactor will ordinarily consist of fissionable material, a moderator, control rods, shielding and fertile material. In addition, there must be structural materials and mechanisms for removing the heat which is produced.

II. NUCLEAR REACTOR PRINCIPLES

1. Multiplication Factor.—The "effective" multiplication factor is a useful concept for studying reactor behaviour. It is sometimes called the criticality factor and may be defined as the ratio of the number of neutrons present following any one generation of fissions to the number present following the immediately preceding generation. If the effective multiplication factor, represented by k_{eff}, is unity, the reactor is critical, and the chain reaction is self-sustaining. If k_{eff} is greater than 1, the neutron density will increase; and if k_{eff} is less than 1, the neutron density will decrease.

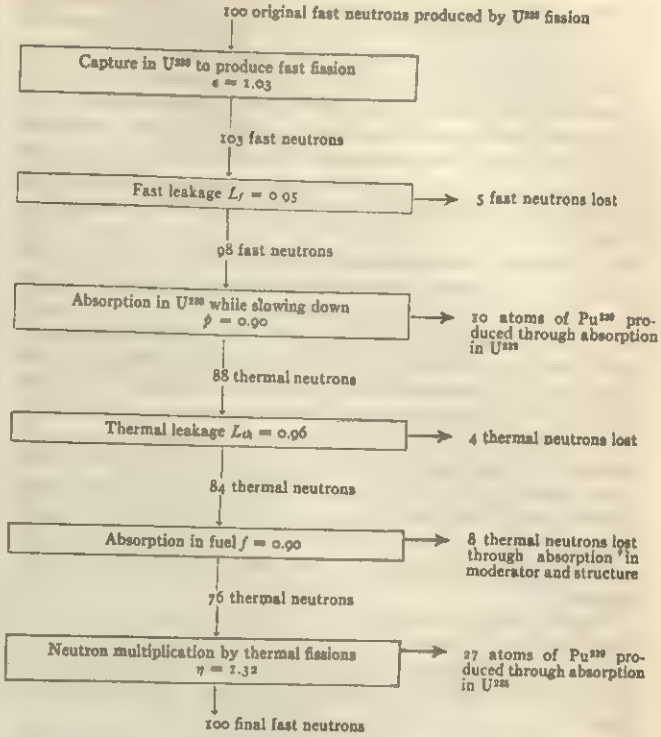
Since neutrons are always lost at the boundaries of a reactor it is convenient to study first a reactor of infinite dimensions, thus making it possible to ignore temporarily the leakages of neutrons through the boundaries. In this case the multiplication

factor is called k_∞, and the determination of its value is a major part of nuclear reactor design.

As shown by the equation $k_\infty = \eta\epsilon p f$, its value may be expressed as the product of four factors: η is the number of neutrons produced per thermal neutron absorption in fuel (this number is smaller than the neutrons released per fission because some of the neutrons are absorbed in fuel without causing fission); ϵ is the fast fission factor, defined as the ratio of the total number of neutrons produced, including the additional production of neutrons by a small number of U^{238} fissions caused by fast neutrons, to the number caused by thermal neutrons alone; p is the resonance escape probability, the fraction of neutrons that are not absorbed while being slowed; and f is the thermal utilization, the fraction of thermal neutrons that are absorbed in fuel.

The factor k_∞ depends only upon the material in the reactor and must be corrected for leakage in any actual reactor design. Neutrons which have collisions near the edges of a reactor have large probabilities of escaping. It is convenient to separate the leakage factor which applies while the neutrons are slowing down from that which applies while the neutrons are thermal. The "effective" multiplication factor for a finite reactor is then written as $k_{eff} = k_\infty L_f L_{th}$ where L_f is the fraction of fast neutrons that do not escape before becoming thermal and L_{th} is the fraction of thermal neutrons that do not escape before being absorbed. The combination of effects in the formula for k_∞ and due to the leakages are shown for a typical case in the accompanying diagram. The chain is applied to 100 neutrons to make the calculation come out in whole numbers.

Typical Nuclear Chain Reaction



2. Slowing of Neutrons.—In the slowing or moderation process, neutrons generally lose energy at each collision. Since the neutrons slow down in a discontinuous manner, considerable effort has been devoted to finding some smooth mathematical step functions which will describe their over-all behaviour accurately. One such method is the "continuous-slowing-down model" which assumes that the neutrons slow down continuously until they reach thermal energy, at which time they diffuse until they are absorbed or leak from the reactor. This model gives good calculated results for a large range of reactors.

3. Neutron Spatial Distribution.—The neutron density (the number of neutrons found in a unit volume) and the neutron flux (ϕ, the density multiplied by the typical velocity) are not uniform throughout a reactor because of the leakage losses through the outermost surface and because of nonuniformities in fuel arrangement and in neutron-absorbing materials.

The fundamental equation which describes the energy, spatial and time dependence of the neutrons in a reactor is so complicated for most practical applications that approximations must be made. The most elementary approximation is to assume that all neutrons have the same energy and that their spatial distribution may be described by the same rules as those applying to diffusion of gases, or to the diffusion of heat in a conducting material. This one velocity (or energy) model is reasonably accurate for large thermal reactors in which almost all fissions occur at thermal energies. For reactors with fissions occurring at energies above thermal this simple model is not accurate enough. The usual method used is to break the full neutron energy range into discrete blocks and assume that the neutrons have "group average" characteristics while in this energy range. The diffusion equations relating to each separate group are solved simultaneously to give the neutron flux as a function of energy and space. One major limitation to this method is the difficulty of obtaining for high energies the necessary "group constants" with which to solve the equations. This leads to the paradox that the simpler one- or two-group method with empirical constants may give more accurate results than the theoretically more elegant multigroup methods.

For simple geometries, the diffusion equations may be solved analytically, but in practice the reactor design is so complicated that high-speed electronic computing machines are needed to obtain approximate solutions. The digital computer is utilized by all reactor designers as a useful tool by means of which designs can be tried without the expense of building critical experiments. The calculations are complex, some data are uncertain and small errors may be very significant. For a new reactor it may be prudent to carry out preliminary low-cost experiments on a low-energy reactor of the same type or on a subcritical assembly of reactor materials, in order to check the calculations.

4. Reactor Transient Behaviour.—Care must be taken during the operation of a reactor that k_{eff} never be allowed to exceed by much the critical value of unity. Applying a very simple analysis, since k_{eff} is the number of neutrons left after one neutron has completed its cycle, then $k_{eff} - 1$ or Δk is the number of extra neutrons per cycle per starting neutron. Thus the gain each cycle for n neutrons is $n\Delta k$, and if the cycle time is l seconds, the gain in neutrons each second is $n\Delta k/l$. This relationship leads to the exponential expression $n/n_0 = e^{\Delta k t/l}$, where n_0 is the original neutron density; n is the time-dependent neutron density; t is the time after Δk appears; and l is the neutron cycle time which would appear to be of the order of the lifetime of a free neutron, which is 10^{-5} to 10^{-2} sec. Since this is so short, it would appear that very small values of Δk would cause the neutron density (and consequently, the power level) to rise exponentially at a very rapid rate. This is unacceptable since uncontrolled power increases can damage the reactor and perhaps create a serious hazard. Therefore, this analysis seems to indicate that safe operation of a reactor is virtually impossible, because it demands an impracticably accurate control of k_{eff}.

However, in this simplified analysis it has been assumed that all neutrons are produced at the instant of fission, whereas in fact some of them are delayed. These are emitted a short time later from some of the fission products, and they constitute about 0.75% of all neutrons. They introduce a sluggishness into the response of the reactor to changes in k_{eff}. The sluggishness is roughly equivalent to a neutron cycle time, l, of 0.1 seconds under normal conditions. Safe operation of reactors is therefore practicable because the control of k_{eff} need not be so accurate as at first indicated. Nevertheless, if Δk should become larger than this delayed neutron fraction, the chain reaction is then no longer dependent upon the delayed neutrons, and it becomes "prompt critical," a dangerous situation since the rate of power level increase can become extremely fast.

5. Reactor Control and Instrumentation.—The primary control of the reactor is through measurements of the neutron flux. This is not only because the neutron flux increases in proportion to

the power level, but also because neutron-sensitive instruments inherently have very quick responses. The wide range of neutron flux, varying by factors of as much as 10^{10} from start-up to full-power operation, requires the use of a variety of instruments with overlapping ranges since no single instrument could cover this whole range. These instruments are used to activate the control system, consisting of the addition or removal of neutron-absorbing material. A large number of auxiliary control and alarm devices may be used in addition to the nuclear instrumentation for adequate understanding and control of operating conditions at all times.

The control system must be devised so as to provide for immediate shutdown in the event of any emergency. In addition it must take account of changes in k_{eff} which occur during routine operation. For example, k_{eff} may have a "temperature coefficient"; *i.e.*, its value may be affected by the temperature of the fuel or moderator. If the coefficient is negative, it tends to be self-correcting from a safety standpoint because an increase in temperature reduces the reactivity. With a positive temperature coefficient a much greater burden is placed on the control system.

The control system must also offset the changes in time caused by the burnup of the fuel and due to the accumulation of fission products. The latter is referred to as fission-product poisoning because of the strong tendency of some of the products to absorb neutrons.

To offset all of these changes, the control system must contain large amounts of excess k_{eff} to be used only as needed. To avoid premature use of this excess reactivity is one of the prime safety problems in the design of a reactor. (*See* also NUCLEAR INSTRUMENTS.)

6. Heat Production.—A characteristic feature of a nuclear reactor is that heat can be produced at almost any desired rate. The upper limit on the rate at which the fissions may be allowed to occur depends not upon the fission process or upon the chain reaction, but simply upon ability to safely remove the heat which is generated. The fission energy appears almost immediately as heat, and if it is not removed fast enough, the temperature of the reactor will rise until the materials of construction begin to melt or are damaged in some other manner.

A major problem of reactor design is, therefore, to devise schemes for transferring large amounts of heat quickly. Power densities of several thousand kilowatts per litre of core volume may be considered, and it is necessary to use materials of construction and coolants which not only have good heat transfer characteristics but which can withstand very high temperatures.

III. REACTOR MATERIALS AND CONSTRUCTION

Development of reactors is greatly dependent on the selection and development of suitable materials. These must carry out their particular functions while not impeding the chain reaction and not interacting. The environment is hostile, as the unusual radiation and other conditions are liable to impair function and cause interactions.

Materials which may serve as moderators include ordinary water, heavy water, beryllium and graphite. Each of these meets the requirement of containing elements of low atomic weight which are poor neutron absorbers.

Ordinary water has the advantage of containing hydrogen atoms, which are small, but an important disadvantage is that these hydrogen nuclei occasionally absorb neutrons. The oxygen atoms contained in the water are poor absorbers but they are fairly heavy, thus contributing little to the slowing down process.

Heavy water has the advantage of containing atoms of deuterium which, although not quite as small as the hydrogen atoms, are much less likely to absorb neutrons. Heavy water is expensive, however, and both light and heavy water have the disadvantage of requiring high pressure for containment at high temperature.

Beryllium is an excellent moderator from the standpoints of the size of its atoms, of its neutron-absorption power and of its ability to withstand high temperature, but again it is expensive and it is difficult to machine and fabricate.

Finally, graphite has been used extensively. Its atoms are not ideally small, but they are also poor neutron absorbers, and the temperature properties of graphite are excellent. However, it has the disadvantage of being adversely affected by continued exposure to neutron and gamma irradiation.

When used to surround the entire core of the fuel-bearing region of the reactor to retard the escape of neutrons, the moderating material is called a reflector. It does not reflect neutrons as a mirror reflects light, but random collisions occur in it and some neutrons which would otherwise be lost are returned to the reactor core. By conserving neutrons, a good reflector always reduces the fuel requirement for a reactor.

The coolant for a reactor is usually a fluid, either gaseous or liquid. Desirable coolants have good heat transfer properties, the ability to withstand high temperatures, low neutron-absorbing properties and, of course, low cost. Both light and heavy water have been used, as well as liquid organic materials, fused salts, liquid metals such as sodium, and air and carbon dioxide. Helium and nitrogen are also possibilities.

As a coolant, water again has the disadvantage of having to be pressurized at higher temperatures, whereas both the liquid organic materials and liquid sodium may go to much higher temperatures without pressurizing equipment. It is found, however, that the organic materials tend to deteriorate chemically under radiation exposure, and liquid sodium is difficult to handle because of its chemical properties and because of the intense radioactivity which it develops under neutron bombardment. Air and carbon dioxide have desirable temperature and heat transfer properties, but both absorb neutrons and acquire undesirable radioactivity. Helium has excellent heat transfer characteristics and it does not become radioactive, but it is extremely difficult to contain, thereby giving rise to special pumping problems.

Structural materials are required to hold the reactor together to channel the coolant, to form control rods and to clad and protect the fuel. These materials must perform satisfactorily under prolonged and intensive neutron and gamma irradiation. Also, they must be poor neutron absorbers.

The gross physical properties of most materials will eventually change under intense irradiation. Coolant molecules are broken up into smaller molecules or into their constituent atoms. Crystalline lattices, characteristic of metals and ceramics, are distorted or strained through a shifting or removal of constituent atoms. Furthermore, the atoms may be transmuted into different elements altogether.

Radiation damage may also be due to the thermal "spike" caused when the kinetic energy from a single fast neutron, for example, is absorbed in a very small region. The highly localized peak temperatures, perhaps exceeding 5,000° C., may cause alterations in the properties of the material. From a macroscopic point of view these effects are manifested as hardening and embrittlement in metals, discoloration and hardening or softening in plastics and decomposition in water and in organic materials. Some forms of radiation damage can be annealed, and the annealing may occur at working temperature.

In addition to radiation damage, corrosion problems tend to be accentuated within a reactor because of high temperature and more uniquely, because of the particle bombardment which is believed to alter chemical reactivity by causing ionization.

Induced radioactivity due to neutron exposure is another complication. Aluminum, for example, becomes radioactive with a half life of 2.3 min. In other words, the activity decreases to half of its value during this short period. Iron, on the other hand, contains a particular isotope which becomes radioactive with a half life of three years. If it is necessary to remove the material from the reactor for any reason, the aluminum obviously is preferable from the standpoint of dangers in handling.

Materials which have been widely used in structural elements within the reactor include stainless steel, aluminum and zirconium. The chief disadvantage of stainless steel is high neutron absorption by iron; the melting point of aluminum is low; and zirconium is expensive and difficult to fabricate.

Consideration must be given to the internal heat generation which takes place due to the absorption and scattering of radi-

tion. As a result, excessive internal stresses may develop in materials within and adjacent to an operating reactor unless adequate heat removal methods are provided.

The different combinations and arrangements of materials for coolant, moderator and structure provide a large variety of reactor concepts for consideration. *See* also METALLURGY: *Metallurgy in Nuclear Engineering*.

IV. RADIATION HAZARDS AND SHIELDING

Although it is occasionally necessary to shield certain reactor system components from the radiation in order to minimize radiation damage, the protection of operators and other personnel in the vicinity is the major purpose of reactor shielding. For example, for a high-power reactor without any shielding, personnel would have to remain at a distance of at least five miles in order not to be harmed by the radiation.

The unit of radiation dosage applied to humans is called the rem (the rem is that dosage of radiation having the same biological effect as 1 rad of X-radiation; the rad, in turn, is defined for any radiation as the amount that releases an energy of 100 ergs per gram of matter). A person being X-rayed for some diagnostic purpose may receive a dosage of about 1 rem. A dose of 25 rem is commonly applied for the removal of local growths. Dosages of 450 rem or above are likely to be lethal. The recommendation of the International Commission on Radiological Protection is that no individual should receive more than 5 rem per year, with a maximum exposure in any period of 13 weeks of not more than 3 rem. The dosages to which human beings are continuously exposed from cosmic rays and from radioactive materials in the earth and atmosphere are much smaller than this amount.

In the vicinity of a typical power reactor core the radiation intensity must be reduced by a factor of 10^{10} to 10^{12} if human beings are to enter the area. Since the gamma rays and neutrons are highly penetrating, large masses of material are required to reduce the intensity of these radiations to tolerance level.

The mechanism for absorbing fast neutrons is somewhat different from that for gamma rays. They must be slowed down and then captured. The shielding material, therefore, should contain a combination of light atoms and atoms, such as cadmium, boron and hafnium, with high absorbing power for slow neutrons.

The attenuation of gamma rays, on the other hand, depends upon the density of the material. The heavier the atoms, the smaller the thickness required. In practice, therefore, to shield for both neutrons and gamma rays a combination of the two types of material is used. Because of its high hydrogen content and its availability, water is the most commonly used neutron shield. In applications where there is no premium on keeping the shield small, water may also be used effectively as a shield for gamma rays.

For stationary power reactors a homogeneous mixture, such as concrete, is normally used. This has the advantage of being relatively inexpensive, of containing hydrogen atoms to aid in slowing down and capturing neutrons and of having a relatively high density to promote absorption of gamma radiation.

For mobile reactors, such as those for nuclear propulsion of an aircraft, the weight of the shield is of overriding importance, and its cost is secondary. In this instance laminated layers are almost always used because of their reduced weight. One of the laminations will consist of materials of low mass number for the neutron attenuation, and the other lamination will consist of a high mass number to attenuate the gamma rays. Also, for this particular application full advantage is taken of the attenuating effect of distance and of shadow shielding; *i.e.*, the shielding of a small area such as the crew compartment is accomplished by interposing a small shield between the compartment and the reactor instead of completely around the reactor.

V. RADIOACTIVE WASTES AND DISPOSAL PROBLEMS

The accumulation of radioactive waste materials is one of the major problems confronting nuclear engineers. With the ever-increasing amounts of material which give off alpha, beta and gamma radiation, it becomes more and more difficult to make certain that human beings are never exposed to anything more than very tiny radiation levels.

The alpha and beta rays have very low penetrating power and are usually not harmful unless the waste material emitting these radiations is taken internally. In this case there may be direct exposure, perhaps over extended periods of time, of vital parts of the human body. Therefore it is necessary to make certain that contamination of water and air by such materials is kept below tolerable limits.

Radioactive wastes may exist as liquids, solids or gases, and they are usually classified, by the intensity of the emitted radiations, as either high-level or low-level wastes. When the emitted radiation intensity is sufficient to reduce the time a human being can remain near the material, it is considered high-level. On the other hand, if the waste material can be handled directly without undue consideration being given to the time of contact (radiation intensities up to 0.05 rem per hour), it is considered low-level.

The major source of radioactive waste materials is from the fission process itself. Almost all of the fragments are intensely radioactive, with half lifes varying from a few seconds up to thousands of years. In time the radiation level of these materials decreases, but on the average this radioactive decay is so slow that it alleviates the waste disposal problem only slightly.

Radioactive materials are also induced by radiation within a nuclear reactor. Certain radioisotopes are deliberately manufactured in this manner and others are necessarily produced in connection with operation of the reactor. For example, if air is used as a coolant, radioactive isotopes of oxygen, nitrogen and argon will be produced as well as radioactive materials from particles of dust and other impurities found in the air.

One method of reducing the radiation level of radioactive waste materials to tolerable levels is simply by dilution and dispersion. The aim is generally to reduce the concentration of the offending isotope to less than $\frac{1}{10}$ of the limits considered tolerable. Care must be taken, however, to make sure that there is no reverse process which will reconcentrate these materials; for example, involvement in the life cycle of some organism found in the sea where the waste material may be dumped.

Gases and most low-level aqueous wastes are disposed of by dilution and dispersion. The gases—for example, those used for reactor cooling—are usually diluted with large volumes of air and discharged to the atmosphere through high stacks. If the gas contains particular matter, it is passed through filters and electrostatic precipitators before being discharged.

Dilution is also used extensively in disposal of reactor cooling water and relatively low-level aqueous wastes. But most such wastes are stored for a short period prior to release to allow isotopes with short half lifes to decay. After dilution and dispersion in a river, lake or the sea, the concentration of the active isotopes must be low enough to be below drinking water tolerances—approximately 10^{-11} curies per litre. The total volume of low-level liquid wastes disposed of in the United States by this technique in 1956, for example, was nearly 9,000,000,000 gal.; the cost of disposal was more than $1,500,000; both figures increased in succeeding years.

The highest-level wastes are the fission products taken directly from nuclear fuel. For reactors with liquid fuel, the fission products may be continuously removed as a part of the process of operating the reactor. But for fuel in solid form, the fuel elements must be taken from the reactor from time to time and processed separately, not only to remove the fission products but also to separate the unused fuel to make it available for manufacture of new fuel elements. In either event, high-level radioactive wastes accumulate in abundance, and their level is far too high to consider dilution and dispersion. The only other method of waste disposal is to concentrate and store the material. Its bulk may be reduced by evaporation, and the condensate then can be treated, if possible, as low-level waste. Large amounts of the high-level concentrate have been stored in underground tanks. Another method of storage is to fix the fission products into an inert solid carrier, such as blocks of concrete, so that they cannot escape. These blocks are then buried or stored indefinitely in a

remote area. Still another procedure is to remove those particular isotopes which have long half-life periods and high radio toxicity, such as strontium-89 and cesium-137. This reduces substantially the radioactivity level of the remaining material and facilitates its disposal. It is also possible to store high-level wastes in underground geologic formations, such as salt beds, salt domes and deep basins with no connection to potable waters or other natural resources.

VI. NUCLEAR REACTOR TYPES

Nuclear reactors may be classified according to design in several different ways depending on the types of fuel, moderator and coolant used, on the arrangement of these compounds and on the velocity of the neutrons sustaining the chain reaction.

In addition, reactors may be classified according to their purpose. Research and test reactors are built primarily to supply neutrons for physical and biological research, for testing of materials and for manufacture of radioisotopes. Production reactors are built to manufacture fissionable materials by converting fertile materials. Reactors capable of producing heat in sufficient quantity and at temperatures high enough to have practical use are known as power reactors. Sometimes more than one of these purposes are served simultaneously by a single reactor.

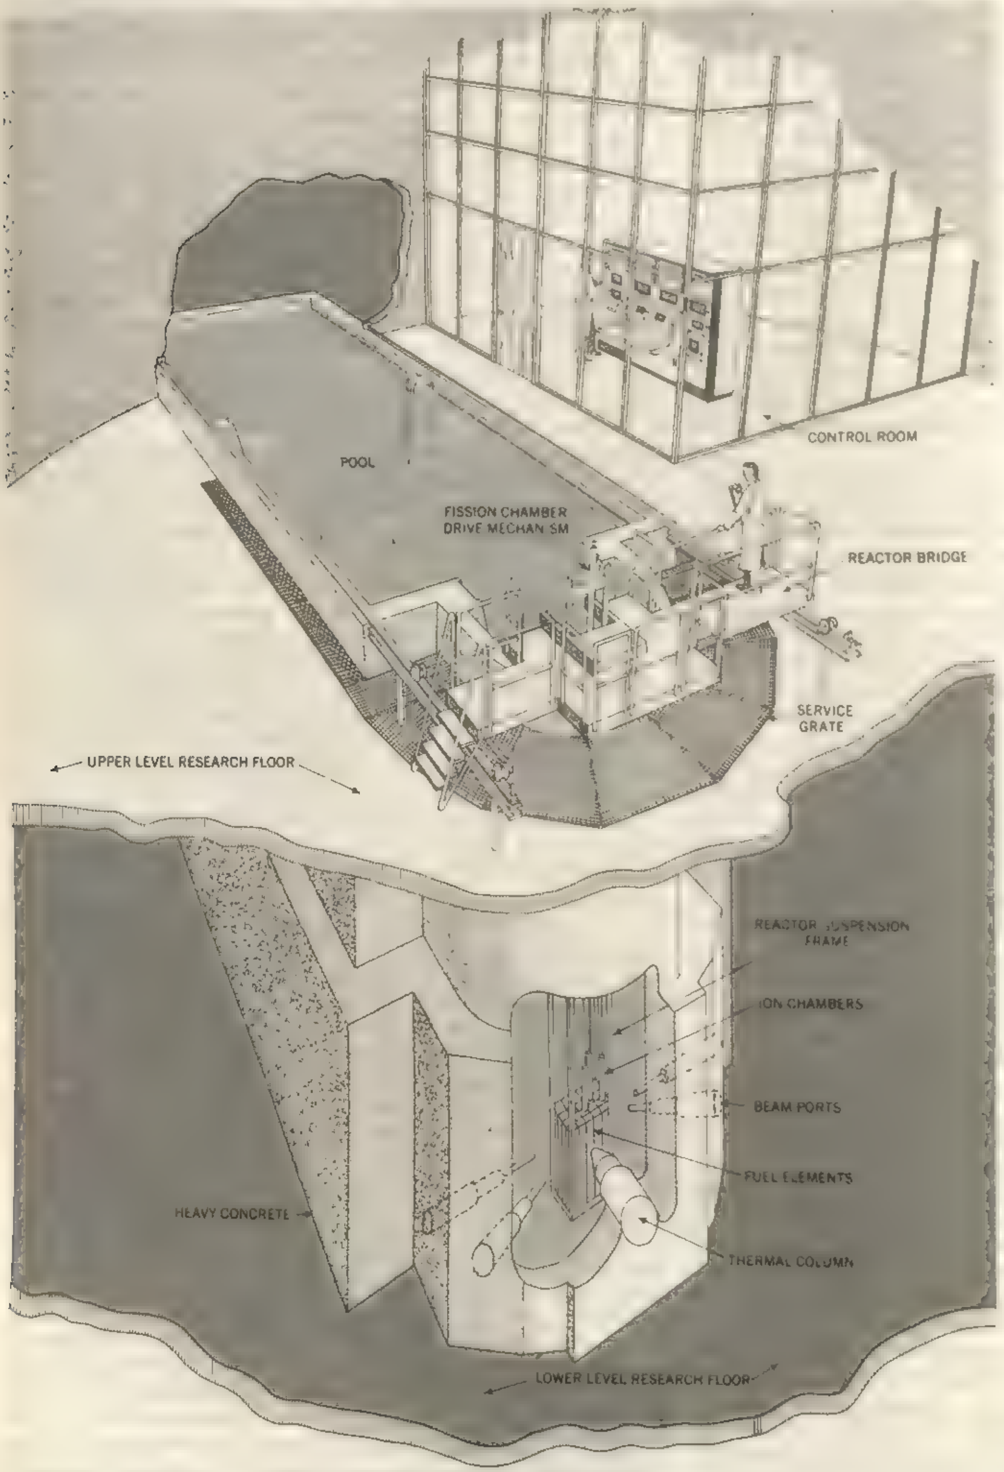
To classify reactor types solely on the basis of design, or solely on the basis of purpose, fails to emphasize those types which are of greatest interest because of past experience or because of their promise for advancement of the technology. Instead it is customary to group reactors primarily on the basis of their chronological development.

1. Heterogeneous Natural-Uranium Reactors.—The world's first self-sustaining nuclear chain reaction was achieved in an experiment at The University of Chicago on Dec. 2, 1942. Natural uranium metal rods were placed between alternate blocks of graphite, which served as moderator. In such a design, where the fuel is distributed in a fairly definite geometrical pattern or lattice within the mass of the moderator, the reactor is referred to as heterogeneous.

The large plutonium production reactors built originally at Hanford Works are of the heterogeneous type, using natural uranium and graphite, and cooled by ordinary water. The research reactor at the Oak Ridge (Tenn.) National laboratory, commonly referred to as X-10, is also graphite-moderated and uses natural uranium. The graphite cube in this reactor measures about 25 ft. along each edge and is traversed by several hundred equally spaced, cylindrical channels. These channels are loaded with 1.1-in.-diameter aluminum-clad cylinders of metallic uranium; the aluminum is to keep the fission products within the fuel. Cooling is achieved by air flow through these channels.

Another example of a heterogeneous natural uranium reactor was the Calder Hall type built in Great Britain, the first reactor to produce electric power on a commercial scale. The moderator is graphite, and the heat is removed from finned fuel elements by carbon dioxide, which is pumped through the fuel element channels under pressure.

Heavy water can also be used as a moderator with natural uranium. The NRX, completed in



BY COURTESY OF AGRICULTURAL & MECHANICAL UNIVERSITY OF TEXAS

BY COURTESY OF U.S. ATOMIC ENERGY COMMISSION

FIG. 2.—SCHEMATIC DRAWING OF A URANIUM-FUEL NUCLEAR REACTOR

Aug. 1947 at Chalk River, Ont., is an early example. Aluminum is used to clad the fuel elements, and ordinary water is pumped through the fuel element channels as a cooling fluid.

Heavy water also shows promise for use in large power reactors fueled with natural or perhaps slightly enriched uranium.

2. Heterogeneous Enriched-Uranium Reactors.—With the use of enriched uranium, the size of the core required to sustain the chain reaction may be greatly reduced. For example, the material testing reactor, located at Arco, Ida., has a core with over-all dimensions of about 9 × 27 × 24 in. The uranium is enriched to more than 90%, then alloyed and clad with aluminum in the form of curved plates. The reactor is water cooled and operates at a relatively high power level (40 megawatts) to produce high neutron fluxes for research and test purposes.

The pressurized water reactor at Shippingport, Pa., was the first in the United States to produce substantial amounts of electric power for commercial use. In it, the water serves both as moderator and coolant. The fuel elements are of two types: most of them are tubes of zircaloy (an alloy of zirconium) containing natural uranium oxide pellets; to permit attaining the critical state, the core is "seeded" with a smaller number of plate-type fuel elements, also clad with zircaloy but containing uranium enriched to 93% and alloyed with zirconium.

Heterogeneous reactors containing organic materials as coolants also showed promise because of the lower operating pressures which are possible. Slight enrichment is necessary for reactors of this type, except perhaps when heavy water is used as a moderator.

3. Boiling Water Reactors.—There are some advantages to generating steam within the reactor core. It has been found that a water-moderated reactor can be made to operate stably while the water is boiling in the core. The steam produced may be used directly to drive a turbine or passed through an intermediate heat exchanger to generate steam in a secondary turbine loop.

The experimental boiling water reactor at Argonne National Laboratory, Lemont, Ill., has a cylindrical core, approximately four feet in each dimension, containing interchangeable natural and enriched uranium plate-type fuel elements. Either natural or forced circulation of the water is possible. The reactor is constructed to permit operation with heavy water as the reactor coolant and moderator.

4. Fast Breeder Reactor.—The fissions in this type of reactor occur at high neutron energies since no moderator is provided to slow the neutrons. Attainment of the critical level necessitates relatively high enrichment and large fuel mass. The Enrico Fermi reactor, Detroit, Mich., consists of zirconium-clad fuel pins enriched to 27% in U^{235} and cooled by liquid sodium. Surrounding the core is a "blanket" of uranium, consisting primarily of U^{238}. Conversion to plutonium occurs more easily with the faster neutrons, and it was anticipated that plutonium would be produced in this blanket at a rate equal to or exceeding that at which the U^{235} was consumed.

5. Homogeneous Reactors.—A reactor in which the fuel material is more or less evenly dispersed throughout the moderator is known as a homogeneous reactor. One type utilizes a uranium salt, such as uranyl sulfate, which is dissolved in ordinary or heavy water and is contained in a corrosion-resistant metal vessel. As energy from the chain reaction heats this fluid, power may be obtained by circulating it to an external heat exchanger. An advantage of this reactor is that it permits continuous removal of fission fragments and continuous refueling. The problem of reactor "poisoning" is therefore minimized, and the costly fabrication and processing of fuel elements necessary with heterogeneous reactors is eliminated.

The homogeneous reactor test facility at Oak Ridge, Tenn., had a 32-in.-diameter zirconium alloy core tank which contained a uranyl sulfate-heavy water solution having a concentration of approximately 10 g. of U^{235} per litre. Plutonium could be produced either from U^{238} in the solution or in a blanket. One of the major problems connected with this type of reactor has been the highly corrosive character of the solution.

6. Research, Test and Training Reactors.—The earlier research reactors used natural uranium, but with the availability of enriched uranium for fuel it has been possible to effect substantial reductions in cost for reactors of more recent design.

One of the more popular types, providing moderate neutron fluxes (10^{12} to 10^{13} neutrons per square centimetre per second) is called the "swimming pool" reactor. This has a reactor core suspended in an open pool of water. The water serves as coolant, moderator, radiation shield and neutron reflector. Plate-type fuel elements, highly enriched in U^{235}, are ordinarily used.

For higher neutron fluxes (10^{13} to 10^{14}) a better cooling system is needed if ordinary water is retained as the moderator; therefore a closed cooling system with a tank reactor is generally used. In a tank reactor the core is located within a closely fitting tank through which water is pumped to carry away the heat. This type lacks the simplicity of the swimming pool reactor, and the core is not so easily accessible for research purposes. Even though the core is small in order to obtain a high power density, the tank is designed in such a way that materials to be irradiated for research and test purposes may be inserted directly into the core. In addition there are openings for test purposes, also yielding high fluxes, in the blanket of these reactors.

The first research reactors using enriched uranium were of the homogeneous type, commonly called "water boilers," even though boiling was not permitted. The core consisted of a stainless steel spherical shell, about one foot in diameter, which contained the aqueous fuel solution. The heat was removed by a cooling coil wound through the inside of the sphere. This design, which is characterized by low fuel inventory and a relatively high neutron flux in relation to its low power level, has a high degree of inherent safety.

A heavy water research reactor has a lower mass of fissionable material and a higher thermal neutron flux than a comparable light water reactor designed for the same power. The thermal neutron flux distribution across the core is relatively flat, and consequently this reactor type provides a large experimental volume at a comparatively high flux level.

VII. FUELS AND FUEL RECOVERY

Three nuclides, U^{235}, U^{233} and Pu^{239}, undergo fission with thermal neutrons and therefore have received major consideration as nuclear fuels for industrial purposes. Relatively large quantities of Pu^{239} have been produced, but this nuclide has found its major use in weapons production. Commercial power reactors will in due course produce surplus Pu^{239}. U^{233} has also been produced, but in considerably smaller quantities, and it has been used principally for experimental purposes. U^{235} remains, therefore, of primary interest for industrial applications.

Since nuclear reactors are inherently incapable of consuming all the fuel they contain, the fuel elements taken from heterogeneous reactors will always contain substantial amounts of fuel. The recovery of this unused fuel from solid fuel elements so that it may be reused generally reduces the total fuel cost.

There are many different kinds of solid fuel elements. The

major considerations involved in their design include not only nuclear characteristics but also heat transfer and coolant flow, radiation damage, corrosion, mechanical strength and the containment of fission products.

In order to minimize the cost of reprocessing the fuel and of refabricating the new fuel elements, it is desirable to leave the fuel in the reactor as long as possible. Pure uranium metal makes a poor fuel element because it is susceptible to radiation damage, it is very reactive chemically, and it undergoes three solid-phase transitions below its melting point. Thermal cycling causes severe and permanent distortion in shape and volume. Substantial improvements are made by alloying the metal with appropriate diluent metals and by use of chemical compounds of uranium, such as uranium oxide and uranium carbide.

The basic materials for most reactor fuel elements are of three types: metallic fuels contain uranium metal or uranium metal alloys; ceramic fuels are sintered compacts of uranium compounds; and cermets are dispersions of uranium compounds in a metal matrix.

These materials are ordinarily formed into flat or curved plates, rods or hollow tubes, and then are clad completely with a thin metal sheath that protects the fuel material from corrosive attack by the coolant and prevents fission products from contaminating the coolant. Geometric arrays or clusters of the individual plates, rods or tubes of the clad fuel material form the active portion of a fuel element. End boxes of inert materials are often attached to both ends of the active portion to hold the fuel element in place in the reactor core and frequently to direct the flow of coolant through a particular section of the core. Thus, the finished fuel element generally contains a rather high ratio of inert to active material.

Fuel recovery is the technology of separating fission products and diluent materials from irradiated fuels and converting the purified fuel to a reusable form. Chemical processing of used fuel has been the only method utilized on an industrial scale.

Basically, chemical processing consists of two steps: fuel dissolution and solvent extraction. However, several ancillary steps are required in a complete fuel processing plant.

Used fuel elements are first stored temporarily, then transferred to a fuel stripping facility where all easily separated inert material, such as end boxes, side plates or cladding, are stripped from the basic fuel material by chemical or mechanical processes, or both. The stripped fuel is dissolved in a suitable acid solution, which is then adjusted with reagents to produce an appropriate feed solution for the solvent extraction step.

Solvent extraction is the heart of the process because it accomplishes the separation of fuel from the fission products (decontamination) and from all other diluents not previously removed. This is accomplished by intimately mixing the feed solution with an organic solvent that selectively entraps the uranium or plutonium in the feed. The organic solvent, being less dense than and immiscible with the feed solution, is easily separated from it, and the fuel-depleted aqueous feed solution becomes the highly radioactive aqueous raffinate (waste). The fuel-rich organic solvent is then contacted with a stripping solution having a different acid concentration than the feed solution, and the fuel is transferred from the organic solvent to the aqueous strip solution. The fuel-depleted organic solvent now becomes organic raffinate and must be purified in a solvent recovery step before it is reused. If sufficient decontamination has occurred in the first cycle of solvent extraction, the fuel-rich strip solution is concentrated and becomes the product of the chemical processing plant, an aqueous solution of uranyl or plutonium nitrate. If not, the fuel-rich solution may be processed through a second and perhaps a third cycle of solvent extraction to achieve the desired degree of decontamination.

If the feed to the solvent extraction cycle contains a mixture of uranium and plutonium, a partitioning cycle, wherein the plutonium is separated from the uranium, is generally interposed between the first and second extraction cycles. Partitioning is accomplished by adding to the first cycle strip solution a reagent that will readily reduce the plutonium from the +VI valence state to the +IV valence state but will not alter the valence of uranium. When this solution is contacted with organic solvent, the uranium is readily extracted while the reduced plutonium remains in the aqueous phase. Thereafter the uranium and plutonium streams are treated separately if further decontamination is required.

Radioactive aqueous raffinates from the solvent extraction, solvent recovery and fuel stripping processes are treated in a liquid waste treatment step to reduce the volume of radioactive wastes that must be stored permanently. The storage of the radioactive wastes is one of the major cost factors in the chemical recovery of used fuel.

The fuel stripping, dissolution, feed treatment and waste treatment steps of chemical processing may be either batch or continuous processes, but the solvent extraction and solvent recovery steps are inherently continuous processes. Continuous processing methods throughout a plant are more economical than a combination of batch and continuous methods; however, the wide variety of fuel enrichments, compositions and geometries encountered are not readily adaptable to continuous processing methods.

Highly enriched fuel must be processed in "critically safe" equipment or be "batch controlled" in order to prevent the inadvertent assembly of a critical mass. The geometry of critically safe equipment is such that it is impossible to achieve a critical state. Batch control limits to less than a critical amount the quantity of fuel that may be admitted to any given vessel.

The kind and quantity of diluent in the fuel mixture has its greatest effect on the dissolution step. Highly corrosion-resistant diluents require chemically sophisticated acids for their dissolution and even more specialized materials of construction in the dissolver. Fuel materials having high diluent-to-fuel ratios result in inefficient dissolver and solvent extraction operation and large waste volumes per unit of fuel processed.

VIII. ECONOMICS OF NUCLEAR POWER PRODUCTION

From an economic standpoint the great potential of nuclear energy for producing electrical energy or motive power lies in the enormous amount of energy released from a relatively small amount of fissionable material. In spite of this, however, the cost of producing power with nuclear fuels has remained high in comparison to the cost with conventional fuels. Present developments indicate that this comparison may be reversed for some applications during the 1960s.

The capital costs of a nuclear power reactor tend to be high because of the complexity of the plant and the large inventory of nuclear fuel. Surrounded by thick concrete shielding power reactors may range from 30 to 60 ft. in diameter, and some require 1,500–3,000 tons of high-purity graphite or 50–100 tons of costly heavy water. While the size of the reactor can be reduced by enriching the fuel, the reduction in capital cost tends to be offset by higher fuel cycle costs. In addition, elaborate and complex mechanisms are required for control. Large storage facilities for coal and oil are not needed, but instead rather elaborate facilities are required for transferring and storing the highly radioactive fuel discharged from the reactor.

The operating costs, in particular the cost of the fuel cycle, remain higher than the conventional counterpart, but with the advance of reactor technology substantial reduction in these costs can be expected. The cost items for uranium fuel include its mining, refinement from ores, enrichment and conversion to a form suitable for use in the reactor. If in solid form, it must further be clad in a protective jacket to prevent the escape of the fission products.

When the highly radioactive fuel elements are discharged from the reactor, they must be stored in shielded pits until the activity has decayed to a sufficiently low level to permit their transportation to chemical processing plants. Even after a period of 100 days or more, the fuel is still radioactive enough to require heavy lead shielding during transportation. Thus, every ton of fuel shipped to the reactor plant must be accompanied by [illegible] tons of shielding when reshipped to the fuel reprocessing plant.

The recovered fuel is recycled back into new fuel elements with additional makeup material to account for the fuel burned. Since the enrichment of the fuel is reduced by fissioning of the U^{235}, the recovered fuel may have to be recycled through a gaseous diffusion plant or blended with a higher enrichment uranium in order to achieve the required enrichment.

Because of the great expense of fuel processing and fabrication, it is clear that substantial savings in the cost of fuel can be achieved by increasing the fuel burnup—in other words, by reducing the frequency with which the reactor has to be recharged with new fuel elements. The obstacles to high burnup are primarily: (1) the accumulation of fission products which "poison" the reactor by absorbing neutrons; (2) the damage to the fuel elements resulting from the effects of radiation; (3) the buildup of contained fission products in gaseous form; and (4) thermal cycling. To offset the poisoning, increased enrichment can be used, but this in turn adds expense because of the cost of compensating for the excess reactivity during the early life of the fuel element when the increased enrichment is not needed, and because of the extra cost of the fuel itself.

An extensive development effort is directed toward means of increasing the burn up of reactor fuel before replacement is necessary. Besides improvements in the physical soundness of the fuel elements, there are under development schemes which involve intentional poisoning of the fresh fuel elements, use of two or more fuel regions of different enrichment and other plans to prolong reactor core life.

Homogeneous reactors also show promise for reduction in fuel costs. With fuel in a fluid form, the expensive and complicated fabrication step is eliminated and continuous chemical processing of the fuel becomes an integral part of the reactor operation. Fission products are continuously removed, providing more efficient utilization of the fuel, and the other obstacles to high burnup found in solid fuel elements are nonexistent.

A reactor which breeds new fissionable material has the important economic advantage of accumulating new fuel at least as fast as it is burned, but the large inventories of fuel and fertile material required at the outset are a strong offsetting cost factor.

IX. OTHER INDUSTRIAL APPLICATIONS

Experience with several experimental vessels clearly demonstrated the technical feasibility of nuclear energy for ship propulsion. The cost remains high in comparison with conventional fuels, but nuclear propulsion has certain inherent advantages which tend to offset these high costs. These include increased cruising range, elimination of the need for carrying liquid fuel except for emergency purposes and for the generation of electricity while in port, and elimination of the need for an air supply or an exhaust system for the power unit. Exploitation of these advantages suggests that ships may be designed for greater earning capacity even if propulsion costs remain about the same.

In general, the types of reactors which appear to be suitable for central station generation of electricity may also be considered for ship propulsion. Greater emphasis in marine service is placed, however, on compactness, reduced weight and operation at the higher temperatures which permit higher thermal efficiency. The design must also allow for the motion of the ship and for the possibility of collision.

The process heat requirements of industry are large in comparison with their requirements for electric power. In certain types of industry where large amounts of heat are needed on a relatively continuous basis, nuclear fuel may prove interesting as a source of energy. The industries having such heat requirements include certain types of food processing, pulp and paper, and chemicals.

Neutrons from nuclear reactors have been used extensively to manufacture radioisotopes with wide industrial and research applications. Large gamma-ray sources may be used for the preservation and perhaps sterilization of certain types of food. In the chemical industry the effects of radiation on materials may in some cases be turned to an advantage through promoting or initiating certain desirable chemical changes. *See* also ATOMIC ENERGY: *Peacetime Applications.*

NUCLEAR INSTRUMENTS. Radiations from atomic nuclei, rather than the nucleus itself, are the usual object of measurement in nuclear instruments. This article therefore deals with devices for measuring numbers and energies of α-rays, β-rays, γ-rays and neutrons. Basic scientific concepts are presented elsewhere. (*See* ATOM; ELECTRON; ISOTOPE; NEUTRON; NUCLEUS; RADIOACTIVITY.)

Because γ-rays and X-rays are so nearly identical, much of γ-ray instrumentation is applicable also to X-rays. (*See* X-RAYS.) Radioactivity and X-rays have similar applications to medical diagnosis and therapy. (*See* RADIOLOGY; RADIATION: BIOLOGICAL EFFECTS.) Detection of protons, deuterons, tritons and heavier ions is similar to α-ray measurement.

CLASSIFICATION AND DESCRIPTION

Physical Basis of Measurement.—All nuclear instruments depend on an interaction of the measured radiation with some matter, contained in the instrument, which may be called the reacting medium. Since each kind of radiation may have a variety of interactions with each form of matter, there is no simple way of summarizing the myriad possibilities. In the table an attempt is made to organize the art according to seven main groups of basic effects. This classification emphasizes the way in which the information about the radiation originates; the way in which it is organized and presented in the instrument reading is treated below, under *Information Obtained.*

Of the classes of instruments represented in this tabulation, the four of greatest general interest (gas-filled instruments, scintillators, photographic methods and neutron counters) are discussed in some detail in the following sections. References on others are given in footnotes to the table.

Gas-Filled Instruments.—When radiation particles (except neutrons) or photons pass through a gas, interaction occurs with the electrons of the gas molecules. Probability of interaction is high for doubly charged α-particles, less for β-rays and very small for γ-ray photons. If the interaction is such that an electron is completely removed from the molecule, an ion pair is formed (the negative electron and the positive molecular ion). This is the simplest and, for nuclear instruments, the most important ionizing process; there are other possibilities, such as attachment of electrons to molecules to form negative ions and dissociation of polyatomic molecules.

Electrical charges available in the gas must be separated, positive from negative, and made to give some visible indication. The simplest means of accomplishing this is by the use of electroscopes

Classification of Nuclear Instruments

Physical basis	Name of instrument or method	Reacting medium
Production of heat	radiation calorimeter, bolometer	solid
Production of light	scintillation and Cerenkov* counters	solid or liquid
Change of electrical property	electrometer, ionization chamber, proportional counter, Geiger counter, spark† counter, spark chamber‡	gas
	crystal counter§, solid-state ionization chamber	solid crystal
	electron multiplier	solid metal surface
Change of chemical property	photographic method	photographic emulsion
	chemical dosimeter¶	solid or liquid
Change of physical state (phase)	cloud chamber♀	supersaturated vapour
	bubble chamberδ	superheated liquid
Nuclear reaction	fission chamber, neutron counter	solid or liquid
Lethal effect	microbial monitor☐	living organism

and electrometers. These are devices which give a visible deflection proportional to the charge stored on their electrodes. When the gas between two oppositely charged electrodes is ionized by radiation, electric current flows through the gas to reduce the stored charge and the deflection. The chamber containing the gas to be ionized (the ionization chamber) may be more or less integral with the device (electrometer) for measuring the ionization current but functionally, at least, one can always think of them as separate.

In applying electron-tube amplification to ionization chambers, the ionization current is made to flow through a large resistance (hundreds or thousands of megohms) and the voltage across this resistance, when ionization current flows, activates the control grid of the amplifier (fig. 1). Special requirements on this first amplifier tube (electrometer tube) are low grid currents and high insulation of the control grid.

The ionization chamber may be used either to indicate average ionization current (current type) or to indicate individual ionizing events (pulse type). In the current type sufficient capacitance C must be parallel with R of fig. 1 to provide a time constant RC large compared with the average interval between ionizing events, whereas in the pulse type this time constant must be small.

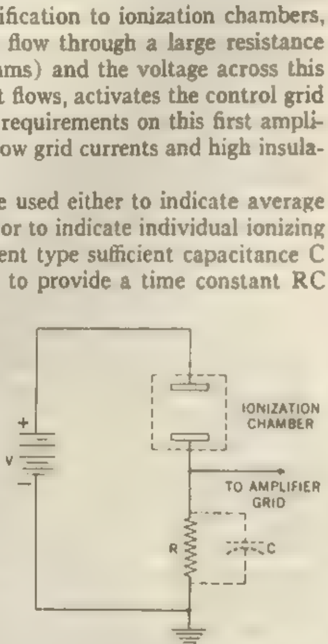

FIG. 1.—IONIZATION CHAMBER CIRCUIT

The amount of battery voltage V supplied to the chamber and the nature of the gas with which the chamber is filled are factors of importance. In principle, neither the battery nor the gas is necessary for charged-particle radiation such as α- and β-rays. In fact, strong α- and β-ray sources can be measured in a vacuum simply by exposing the source to an electrode which intercepts a small fraction of the emitted particles, giving rise to a current in the circuit of fig. 1, even though V is zero. Thus it is clear that the battery voltage and ionizing gas provide a kind of charge amplification, whereby, instead of only one or two electronic charges being collected per incident particle or photon, a large number of ion pairs (hundreds or thousands per centimetre of path) may be formed and collected. (A different avenue of amplification is exploited in the electron multipliers, where the surface on which the primary particle impinges releases several secondary electrons. *See* ELECTRON TUBE: *Photoelectric Devices.*)

An electron released in a primary ionizing event will be accelerated along the voltage gradient existing in the chamber volume. Depending on the nature of the gas, the gas pressure, the distance to the electrode and the voltage gradient, the electron may (1) reach the anode and make its contribution to the ionization current; (2) become attached to a neutral molecule to form a negative ion, which will move much more slowly toward the anode; (3) recombine with a positive ion and be totally lost; or (4), and this is the most interesting possibility, have one or more collisions with neutral gas molecules as a result of which new ion pairs are formed. This secondary increase in number of ion pairs, called gas amplification, is defined in terms of the average number of ion pairs formed by an electron per centimetre of its path along the voltage gradient; it is unity for an ionization chamber (which by definition is understood to be an instrument operated with voltages small enough for this statement to be essentially true).

The voltage on an ionization chamber should be large enough, however, to ensure that substantially all primary ion pairs escape recombination and are collected. Once this "saturation" voltage is reached, a somewhat higher voltage is equally satisfactory, so that a closely regulated voltage is not required. If the voltage is raised to the point where gas amplification becomes noticeably greater than one, there will then be a range of voltage such that at any point in this range the magnitude of current pulse furnished by a given type of particle will be proportional to the particle's energy. An instrument operated in this range is called a proportional counter. The distinction between a proportional counter and a pulse-type ionization chamber is rather subtle since both instruments can be made to furnish output pulses proportional to the ionizing particle's energy. In the ionization chamber the voltage is low (typically, a few hundred volts) and the exact value is not at all critical; there is no gas amplification, so the primary ions must be sufficient in number to drive the electronic amplifier, and therefore only heavily ionizing radiation such as α-rays can be measured. In proportional counters, the voltage is higher (perhaps 1,000 v.) and there is gas amplification possibly as large as 10,000; so, although the output pulse magnitude is proportional to particle energy, the exact value of the large proportionality factor is markedly dependent on voltage. Thus, the ability of the proportional counter to measure energy of weaker radiation, such as β-rays, necessitates a well-regulated voltage supply.

Gas amplification is naturally limited by the fact that the individual multiplying processes, or "avalanches," will, as they become larger, eventually interfere with each other. As voltage is raised above the proportional range, therefore, one finds this interference developing and causing transition to a new mode of counter operation. In this voltage range (typically centred at about 1,400 v.) the instrument is known as a Geiger or Geiger-Müller counter. These G-M tubes give pulses of a size not depending on the energy of the ionizing particle, which simply serves to trigger the discharge in an all-or-none way. Thus the G-M counter serves only for counting but is nevertheless extremely useful, since it may respond to a single primary ion pair. The Geiger discharge is characterized by its rapid spread along the full length of the anode. Once a given discharge pulse is initiated, the entire counter volume becomes insensitive and remains so until the pulse of positive ions is cleared. (The more mobile electrons are very rapidly collected on the anode.) For this reason Geiger counters cannot be made to operate as fast as proportional counters, in which the pulse of positive ions moving toward the cathode is more localized.

The size of pulse from a Geiger counter is more or less proportional to the voltage, and quantitative use of these counters therefore requires a well regulated high-voltage supply. The voltage must be kept below the point at which the electrical discharge becomes continuous. Even below this limit, the G-M counter will give a continuous succession of discharges unless provision is made for quenching. The necessity for quenching follows principally from the emission of secondary electrons at the cathode upon arrival there of the positive ions released in the first discharge. Occurrence of single discharges may be ensured by admixture to the main filling gas of a quenching gas, which suppresses the secondary electron emission.

The choice of gas with which to fill the ionizing volume is important, particularly for proportional and Geiger counters. Current-type ionization chambers generally are filled with air or with the noble gases. In high-quality pulse-type ion chambers and proportional counters it is important to avoid all possible traces of electronegative gases, such as oxygen. Argon is extensively used for all three groups of gas-filled counters, with the addition of one part in ten of ethyl alcohol for quenching in Geiger tubes. Endless varieties of pure and mixed gases have been tried, most with some degree of success. Behaviour of a supposedly pure gas may be radically modified by a trace of another.

Range of gas pressures is also quite wide—from many atmospheres in high-efficiency ionization chambers to small fractions (*e.g.*, one-tenth) of an atmosphere in Geiger counters. Construction is rather standardized for proportional and Geiger counters, viz., a cylindrical cathode, of diameter one inch or less, with a fine-wire anode, a few thousandths of an inch in diameter, mounted along the axis of the cylinder. The large voltage gradient near the fine wire is an essential feature of these instruments. Ionization chamber design is more flexible. Choice of electrode material is important, particularly for γ-ray Geiger counters, which are activated by electrons ejected from the cathode rather than by ionization of the filling gas.

Gas-filled nuclear instruments are an application of one of the most complicated branches of physics. (*See* ELECTRICITY, Con-

DUCTION OF: *Conduction in Gases*.) Crudely contrived devices may work after a fashion, but a precisely quantitative instrument involves careful combination of design factors.

Scintillation Counters.—Visible light plays a minor role in gas-filled instruments, except Geiger counters, where photons are an important ingredient of the discharge mechanism. There are solid materials, such as zinc sulfide, which as early as 1908 were observed under α-particle bombardment to emit tiny flashes of light, visible through a microscope to the dark-adapted eye. By counting the number of flashes, or scintillations, seen on a zinc-sulfide screen a direct measure of the number of incident α-particles is obtained. The only comparably direct observation of nuclear particles is to see their tracks in a cloud chamber or bubble chamber.

The important role of visual scintillation counting in the first quarter of the 20th century was ended by developments in gas-filled tubes and associated electronics. Nevertheless, it was an electronic development which, after World War II, revived interest in scintillators. This was the electron multiplier, mentioned above. If the cathode of such a tube is designed to eject electrons in response to incidence of visible light, the tube is called a photomultiplier. It is an extremely sensitive means for detecting photons. By using a photomultiplier in place of visual observation, scintillation counting becomes competitive with and in some respects superior to gas-tube techniques.

The scintillation counter consists of three essential parts: scintillating phosphor, photomultiplier tube and any optical coupling required between these two. The ability of such an instrument to measure incident radiation properly depends on (1) whether some of the energy of the incident particle or photon is absorbed by the phosphor; (2) whether any of the absorbed energy appears as emitted visible photons; (3) whether any of the emitted photons reach the photocathode; (4) whether the photons cause emission of photoelectrons; and (5) whether the electron multiplication proceeds properly. Each of the three structural elements must be evaluated against these five points.

There are three main classes of phosphor (*see* LUMINESCENCE): inorganic crystals, organic crystals and organic plastics and solutions. In general, fluorescence occurs more rapidly than phosphorescence, so that fluorescence is preferred for fast counters. There is one principal difference between organic and inorganic scintillators. The luminescence process is characteristic of the organic molecules themselves and can occur whether the phosphor molecules make up pure crystals or are dispersed in plastic or liquid solutions. By contrast, the luminescence of inorganic phosphors is essentially related to the crystalline structure, either by way of lattice defects in a pure crystal or, more commonly, by way of impurities deliberately introduced to "activate" the crystal.

Important inorganic phosphors are sulfides of zinc and cadmium, activated with copper or silver; alkali halides (notably sodium iodide), activated with thallium; and tungstates of calcium and cadmium. The first-used organic crystal, naphthalene ($C_{10}H_8$), has been largely superseded by the more efficient anthracene ($C_{14}H_{10}$). Other organic crystalline phosphors include stilbene, terphenyl, diphenylacetylene and quaterphenyl. Plastic phosphors are solid solutions of an organic phosphor in a transparent plastic—for example, 2% of anthracene in polystyrene. An efficient liquid scintillator (about half as good as solid anthracene) is a solution of 0.5% *p*-terphenyl in xylene; numerous other organic solvents and solutes also give good results. The total domain of all phosphor types is seen to be very complex and rich in possibilities.

For the second element of the scintillation counter, the photomultiplier tube, there are available ever-increasing numbers of specially developed types. The spectral response of the photocathode must match to a reasonable extent the colour of light in the scintillations. High luminous sensitivity, large current gain and low "dark current" (noise due to thermionic emission, leakage current, etc.) combine to give a good signal-to-noise ratio. For fast coincidence counting it is important that there be small spread in transit time (the interval between appearance of light pulse at cathode and appearance of current pulse at anode). Transit time and spread in transit time have both been reduced to the order of a millimicrosecond (1/1,000,000,000 of a second).

The nature of the optical coupling of phosphor to photomultiplier depends on the situation. If the efficiency of light collection is unimportant, the phosphor may be at some distance from the phototube, with air intervening. This is wasteful of light for two reasons: the photocathode subtends only a small fraction of the total solid angle into which light is radiated; and no attempt is made to eliminate reflection from the glass surface of the phototube. The first wastage may be minimized by "persuading" the light to leave the phosphor principally in the direction of the tube by giving attention to such optical details as geometrical shape and surface finish. The second wastage is reduced by providing a complete optical path with no large discontinuities in refractive index. By "light piping" through plastic rods, this can be done even over long distances and over curved paths.

Photographic Methods.—Nuclear science and technology have from their beginning made use of photographic materials, for a photographic plate was the means whereby radioactivity was discovered. In addition to the general practices of picture taking (*e.g.*, photographing particle tracks in a cloud chamber) and radiography (*e.g.*, using γ-radiation, like X-rays, to reveal flaws in an iron casting), there are three specifically nuclear applications of photographic emulsions: exposure measurement, autoradiography and high-energy particle studies. In all of these the emulsion is treated in the usual sequence of exposure, development, fixing and washing. (*See* PHOTOGRAPHY.)

Photographic emulsions are dispersions of fine grains of silver bromide (sometimes with a bit of silver iodide for greater sensitivity) in gelatin. Exposure to light or to particle radiation causes some grains of the bromide (those constituting the latent image) to become developable. This means that in the development process spots on these particular grains are first and most rapidly reduced to pure silver. (In physical development, the sensitive specks receive deposits of silver from the developer.) As the silver particles are opaque, the most exposed portions of emulsion are darkest.

Presumably this basic process is essentially the same in all photographic and nuclear emulsions. The primary mechanism, by which some grains become developable, is not fully understood either for light or for nuclear radiations.

Measurement of exposure to radiation usually depends on degree of blackening of a piece of film, although in special cases particle tracks in the film may be counted. This general blackening is similar to radiographic applications, except that here no picture is involved and hence contrast and resolution are unimportant. Various film types have been developed, differing chiefly in the variety of radiation to which they are sensitive and in the total exposure for which they are suitable. Energy dependence of a film can be modified by covering all or part of the film sample with an absorbing coating or shield.

Autoradiography (or radioautography) is a peculiarly nuclear method of studying material structure. A small number of radioactive atoms are introduced into the chemical build-up of the structure. Under the assumption that the radioactive isotope (the tracer) behaves chemically just as would its nonradioactive twin—an assumption which is not always justified, particularly with light elements—one obtains the desired structure, normal except for the fact that some of the atoms eventually betray their locations by radioactivity. A photographic emulsion placed near these atoms will record their positions.

Close proximity of a thin layer of emulsion to the specimen under study is desirable for greatest accuracy, resolution and sensitivity. Special ways of getting emulsion as close as possible include emulsion stripped from its main supporting base, liquid emulsion painted on the specimen, the wet-process method of forming a single-grain layer of crystals directly on the specimen and floating the emulsion on water as a means of applying it directly to the specimen. Resolution down to the region of one micron has been obtained, which is about the limit with visible light. Techniques include both optical density measurement of the developed

image and study of individual particle tracks. For the latter purpose special emulsions have been developed.

Nuclear track emulsions are used a great deal also in high-energy physics to record the passage or transformation of nuclear and cosmic-ray radiations. In ordinary optical emulsions the proportions by weight of halide grain and gelatin are about equal; in nuclear track emulsions, the grain proportion is about six times as large. Nuclear track preparations are also characterized by narrow grain-size distribution and by large thickness of emulsion.

Neutron Counters.—Measurement of neutrons is distinguished from other radiation measurement by the negligible interaction of neutrons with electrons. Hence the process of ionization, so important in most nuclear instruments, is not directly useful for neutron detection. Neutrons do, however, react with atomic nuclei. (*See* NEUTRON: *Detection of Neutrons.*)

Neutron-nucleus interactions are more complex than the relatively simple ionizing action of other varieties of radiation. The complexity is threefold: (1) the large number of nuclear species; (2) the different reactions that may occur between a neutron and any given nucleus; and (3) the strong dependence of cross section (probability) for any one reaction on the energy of the neutron. Besides making neutron instrumentation rich in possibilities, this complexity has the more sinister effect of leading to unexpected troubles caused by interaction of neutrons with the materials of which the instrument is constructed. This is especially important in high-flux measurements, such as are made on nuclear reactors.

Boron is perhaps the most-used material: in ion chambers and proportional counters filled with BF_3 gas or with boron coatings or foils; as a loading for photographic emulsion; and in the boron thermopile, which indicates by thermocouple the heat derived from large neutron flux. Scintillators are being used with increasing success. For example, an anthracene crystal scintillator will detect neutrons quite well via the recoil of its own hydrogen nuclei. Lithium iodide crystal phosphors have proved quite effective because of the large probability of thermal neutron interaction with the lithium-6 nucleus. Scintillators also are used to respond to the γ-radiation emitted when neutrons are captured in cadmium or boron. Since neutrons are often accompanied by γ-rays, which most scintillators detect efficiently, the problem of discriminating between neutrons and γ-rays is important. There is also continued development of fission chambers. The isotopes uranium-238, neptunium-237 and plutonium-239 have fission cross sections that make them especially useful, in the range from 10 kev to 2.5 Mev, for measurement of neutron energy spectra. A combination of three fission chambers, each utilizing one of these isotopes, permits good coverage of the range mentioned. The slow neutrons, for which the plutonium has a large fission cross section, must be screened from the plutonium counter by shields of boron. The 2.5-Mev threshold of the reaction of neutrons on sulfur-32 is also useful.

EVALUATION AND USE

Nuclear instruments are used in a wide variety of situations to obtain many different kinds of information. It is therefore important to evaluate these instruments as to information obtained, as to factors affecting accuracy and as to the best choice of instrument for a particular purpose.

Information Obtained.—Nuclear instruments furnish answers to two kinds of questions: quantitative (how much radiation?) and qualitative (what kind of radiation?).

Taking first the quantitative approach, it is convenient to distinguish information about the source of radiation from information about the radiation traversing space. In either case one may also distinguish the measurement of a total, integrated number of radiation events from measurement of the rate at which events are occurring. This leads to a fourfold classification depicted in fig. 2. In each of the four cells a single word is chosen to characterize the quantity measured. Irradiation instruments give a quantitative indication of how much total radiation has entered a certain space over a certain interval of time. Intensity meters indicate the rate at which radiation is entering a certain space. Activity instruments show the rate at which radiation is leaving a

	integrated action	rate of action
space effect	irradiation	intensity
source strength	depletion	activity

FIG. 2.—QUANTITATIVE CLASSIFICATION OF INSTRUMENT INDICATION

certain source. Depletion instruments show how much radiation has left a certain source over a certain interval of time. For charged-particle radiation, depletion may be measured by the charge built up on the source. Source depletion may also be inferred from other observations, but it is seldom directly measured. So the important categories are irradiation, intensity and activity.

The question "how much?" may be taken to mean "how many?" This is pure counting: irradiation is measured in counts by a counter; and intensity in counts per time unit by a counting rate meter or rate meter. Counter scales usually consist of a combination of high-speed electronic registers (many operate with small neon bulbs) and a lower-speed mechanical register. Typical rate meters indicate by a pointer on a scale marked in counts per minute. Source activity is rated in curies (1 curie = 3.700×10^{10} disintegrations per second) or in rutherfords (1 rutherford = 10^6 disintegrations per second). Choice of a good unit for activity involves an awkward dilemma. Disintegration rate is not a straightforward measure of activity, for it does not specify number and kind of radiations per disintegration—a given source may for example, simultaneously emit β- and γ-rays. Nevertheless, this choice is doubtless better than trying to specify the total radiation, which could hardly be measured by a single instrument in the mixed cases.

For many applications, especially those of a biological nature, an answer to the question "how many?" is not enough. What is needed is an indication of the effect the radiation might have on matter occupying the space in question. A highly available form of matter, air, is made the basis of such a unit. The roentgen (abbreviated r; mr for milliroentgen) is the quantity of X- or γ-radiation such that the associated corpuscular emission (electrons released from air molecules by the photons) in 0.001293 g. of air produces, in air, ions carrying one electrostatic unit of electricity of either sign. The mass is that of 1 c.c. of dry air at 0° C. and 760 mm. pressure. Assuming an average of 32.5 ev of energy required to form an ion pair in air, 1 r corresponds to the expenditure of about 83 ergs in each gram of air. This number may need revision, as more recent measurements suggest that 32.5 ev is about 10% too small. Irradiation instruments calibrated in roentgens are commonly called dosage meters or dosimeters. Intensity meters are called dosage-rate meters and are generally calibrated in r/hr or mr/hr. Source activity can be similarly expressed in a unit abbreviated rhm, which stands for roentgen per hour at one meter.

For nonphoton radiation, such as α-rays, β-rays and neutrons, the roentgen is not available. A similar unit, the rad, is defined for any radiation as that amount which releases energy of 100 ergs per gram of matter. But the biological effects of radiation are not solely dependent on the amount of energy released; it is also a question of how highly localized the energy is. Such considerations have led to another unit, the rem, supposed to be that dose of radiation which has the same biological effect as 1 rad of X-radiation. These rad and rem units, though poorly defined, help to emphasize the variation of biological effectiveness and to ensure careful setting of proper exposure tolerances.

Calibration requires the availability of standards against which the instrument response may be checked. For calibration of the counting mechanism of counters and rate meters there are available electronic pulse generators of various kinds. But for over-all calibration of counters a standard source of radiation must be used. The preparation and use of standard α-, β- and γ-sources is a complicated and difficult art, involving all the considerations discussed below under accuracy. Carefully prepared sources are available commercially.

The situation is simpler for instruments calibrated in roentgens. It is relatively easy to build a standard instrument measuring ionization of air. But when biological effectiveness is brought in, as it

rem units, the requirement of "standard biological tissue" is clearly impossible of fulfillment in any absolute sense.

Turning from the quantitative "how much?" to the qualitative "what kind?" the first question concerns the variety of radiation —whether it is α, β, γ or neutron. Of these four varieties, α-rays are least able to penetrate matter, γ-rays and neutrons are the most capable and β-rays are intermediate. One way, therefore, of distinguishing varieties of radiation is to vary the thickness of absorbing material in front of the counter. In standard air, for example, α-rays are unable to travel more than a few inches, whereas γ-rays and neutrons can penetrate 100 ft. or more. This range of penetration, however, of any given variety of radiation is also a function of the radiation's energy. So the use of absorbers does not always unambiguously identify variety. Some instruments by their very nature will respond only to one variety. This is essentially true of the fission counter for neutrons, because only the neutron has an appreciable chance of causing fission. But instrument response, like absorption, is in general energy dependent as well as variety dependent.

A measurement which helps in identifying variety and is also interesting in itself is the determination of half life (more generally, of time dependence) of radiation intensity. Radiation of a given variety, originating in a given mass of a single species of radioactive nucleus, decays exponentially with a characteristic time constant. Thus the half life, the time for the observed intensity to decrease to half its original (first-observed) value, is characteristic of the nuclear species. These three factors—nuclear species, half life and variety of radiation—are connected; and in cases where the connections are known from previous work, knowledge of any two determines the third (*see* RADIOCARBON DATING).

Energy dependence of absorption and of instrument response has been mentioned above. These two techniques, therefore, give a start on the measurement of radiation energy. Actually, the study of energy distribution, often called spectroscopy in analogy with the similar study of light, is a large and important part of nuclear science. Highly precise instruments have been developed. For charged particles, they may sort out different energies by means of electric and magnetic fields. Crystal diffraction methods are useful for γ-rays and neutrons (*see* ELECTRON DIFFRACTION).

With proper care, the size of pulse obtained from a pulse-type ion chamber, a proportional counter or a scintillation counter will be a measure of the particle or photon energy. These instruments are particularly effective when used with electronic devices, called multichannel differential pulse-height analyzers, which automatically sort out pulses according to size and display the distribution. Nuclear reactions having a well-defined energy threshold are useful, as mentioned above in connection with neutron counters.

An important class of measurement, somewhat related to energy measurement, is coincidence counting, recording the counts from two (or more) counters only when they occur simultaneously. The definition of simultaneity is limited by the counters, especially by the deviations in their time lags.

Examples of coincidence counting would be detection of annihilation radiation—a pair of γ-rays formed when a positron and a negative electron meet and annihilate each other; or detection of β- and γ-rays emitted simultaneously by some radioactive nuclei. The term anticoincidence counting is applied to those cases in which all counts from the two channels are recorded except those occurring simultaneously.

A typical nuclear physics problem is to determine the disintegration scheme of a particular nucleus. Boron-10, for example, has been found to decay after neutron bombardment to lithium-7 by two processes. In about 7% of the disintegrations, an α-particle is emitted with the full 2.79 Mev of energy; in the other 93%, the α-particle carries only 2.31 Mev and the remaining 0.48 Mev appears in a promptly emitted γ-ray. Elucidation of such a disintegration plan requires measurement of variety of radiation, of energy (of each particle or photon) and of activity or intensity (number of particles and photons).

The information obtained from nuclear instruments is usually presented visually by pointer-scale combinations, oscilloscope traces or patterns of lights; qualitative applications of counters make good use of headphones or loud-speakers, in which the rate of clicking is an indication of intensity.

Nuclear instruments are applied to many industrial measurements, yielding information on pressure, liquid level, thickness of strips and coatings, wear, fluid flow, etc. But these devices are beyond the scope of this article.

Factors Affecting Accuracy.—Information from nuclear instruments is limited in accuracy by the fact that radiation and radioactivity are universal. Cosmic rays and radioactivity of the earth and air provide a background count which sets a lower limit to the useful range of instrument indication. To these outside sources of background may of course be added spurious counts from the instrument itself; leakage of charge across insulators and radioactive impurities in materials of construction are sources of this trouble. Fission counters are least subject to background error, since for some fissionable elements so-called spontaneous fission occurs only at the rate of once in several hours. Alpha-counting may be pushed down to about 1 count per minute, but unshielded proportional and G-M counters have a background rate of about 30 counts per minute, which with an inch or so of lead shielding may be reduced below 15 counts per minute. In scintillation counters background is about 1 count per minute per cubic centimetre of crystal. Similar limitations apply to photographic methods, under the general label of fog. In autoradiography the word artifact is sometimes used to denote spurious evidence of radiation. If N radiation counts are recorded in time t, the standard deviation or error, neglecting background, is $\sqrt{N}$ in the count and $\sqrt{n/t}$ in the counting rate, $n = N/t$. If the background alone is counted for time t_b to establish a background rate b, and then in the presence of this background a source is observed for time t_2 to give a total counting rate n_2, the net rate of the source is $n_1 = n_2 - b$, and the standard deviation in n_1 is

$$\sqrt{\frac{n_2}{t_2} + \frac{b}{t_b}}$$

Sometimes a radiation variety giving strong counter pulses is to be measured against a high background of a weaker pulse variety. Examples are fissions against α-particles and α-particles against β-particles. The numerous weaker variety pulses may accidentally bunch together closely enough at some instant to build up in the amplifier what looks like a strong pulse. Much the same problem occurs in counting weak radiation pulses over crests in grid current noise of the first amplifier tube.

Accuracy in measuring a single variety requires discrimination against other varieties which may also be present. In current-type chambers this may be achieved by subtracting currents; thus the γ-compensated neutron chamber has a three-electrode system, one pair of electrodes collecting current from a volume affected both by neutrons on boron coatings and by γ's, the other pair collecting from a volume in which only γ's are effective. The difference of the currents is a good measure of neutrons, provided equal γ-efficiencies are obtained in the two regions between the electrode pairs, as by adjustment of volumes.

Another limitation on counters, especially serious for the full-volume breakdown of G-M tubes, is imposed by dead time, the period during which, after one count has been initiated, the instrument is incapable of detecting another event. Furthermore, even if the counter can generate a very rapid succession of pulses, the electronic indicating system may be unable to resolve them. Electronic pulse shaping, emphasizing the rapidly changing portions of the pulse wave form, can bring great improvement in resolution.

Efficiency of counting means the ratio of counts observed to the total one would like to observe or could observe from the given sources. This involves first the question whether a given particle or photon ever enters the counter; and then the question whether, if it does enter, it will be counted. In the first place, the counter must have some or all of its walls thin enough for the radiation to penetrate; for the soft β-radiation measured in carbon-14 dating, for instance, thin-window counters must be used, or else the sample must be inside the counter.

Other considerations are geometrical—for example, a point source of radiation in free space could register on a counter no more than the fraction F of its emission, where F is the ratio of the effective solid angle, subtended by the counter relative to the point source, to the maximum possible solid angle, 4π steradians. If the counter can be made to surround the source completely, as when a small source is embedded within a scintillator, total (or 4π) counting becomes possible. Shape and dimensions of the source have an effect not only on counting geometry but also on scattering and absorption.

Scattering is pronounced for electrons, and the backscattering from a reflector may be used to increase by 50% the count from a β-source. Absolute counting refers to the effort to assign an accurate value, based on the observed count, to the total number of radioactive atoms in the sample. Scattering, absorption and efficiency are all of great significance to absolute counting.

Evaluation for Various Applications.—In addition to basic technical factors discussed above, there are practical matters such as cost, size, reliability and portability to be considered in making the best choice of instrument for a particular application. Simple, open-to-the-atmosphere, air-ionization chambers are admirably suited to moderate-accuracy rate-meter applications at medium to high levels, as for military and civil defense needs. In dosimetry the fountain-pen-size condenser r-meter and the film badge are most useful for monitoring personnel. The condenser r-meter is a roentgen meter, or dosimeter, consisting of an electrometer chamber giving an initial electric charge, worn by the user and then measured for charge lost, which indicates the total ionizing radiation received. Chemical dosimeters have the advantage over film badges of being easily and quickly read.

Geiger counters combine sensitivity at low counting rates with relative simplicity. An example of an inexpensive assembly would be a Victoreen-type 1B86 counter tube, a 1-megohm resistor, a miniature 300-v. battery, a pair of high-impedance magnetic headphones and an on-off switch—all connected in series. G-M counters are sensitive, reliable and portable enough to be very useful in prospecting for radioactive ores. For this purpose the more sensitive but more expensive scintillation counters are also in wide use. For prospecting (*see* GEOPHYSICAL PROSPECTING), an upper limit on scale range of 5 to 20 mr/hr. suffices, as background at earth's surface averages 0.02 to 0.05 mr/hr., and a count of several times background is encouraging (but not conclusive!) evidence of mineral radioactivity. The scintillator method is extremely flexible as to counter volume. For a medical dosimeter probe a tiny crystal may be used on the end of a light-piping plastic rod; at the other extreme, large volumes of liquid scintillator surround a counting chamber large enough to receive a human body. Liquid scintillators of large volume also played a key role in detection of the neutrino, most elusive of fundamental particles (*see* PARTICLES, ELEMENTARY).

Accurate nuclear measurement can be achieved only if a good instrument is used with good auxiliary equipment. For example, medical dosimetry of γ-emitters such as radioiodine may be wrong by a factor of two because of scattered radiation, but this error may be largely eliminated by using with the counter a collimator that will accept only rays coming from a highly limited direction, and by feeding the counter output to a pulse analyzer which permits counting only peak, unscattered pulses. Other auxiliary items useful on occasion include automatic counting timers and sample changers; flow controls for liquid or gaseous samples; shielding and absorbing materials; and devices for remote handling of dangerously strong sources.

NUCLEAR MAGNETIC RESONANCE, a technique for observing the magnetic character of atomic nuclei through a resonant response to a high frequency magnetic field when the nucleus is placed in a static magnetic field.

Approximately two-thirds of the stable and almost all of the unstable atomic nuclear species possess angular momentum, called nuclear spin. As required by quantum mechanics, the magnitude of the angular momentum is a half-integral multiple of $h/2\pi$ where h is Planck's constant, 6.625×10^{-27} erg-seconds. Accompanying the spin is a magnetic dipole moment, as if electric charge were circulating around the axis of the spin (*see* NUCLEUS: *Further Properties of Nuclei*). The convenient unit for the specification of the magnitude of nuclear magnetic moments is the nuclear magneton.

A particle with the charge and mass of a proton, the simplest nucleus and a constituent of all others, would have a magnetic moment of one nuclear magneton, if it rotated as a rigid body with one unit $h/2\pi$ of angular momentum. The proton actually has a spin of one-half $h/2\pi$ and a magnetic moment of 2.7899 nuclear magnetons.

In a static magnetic field, the torque acting on a nucleus through its magnetic moment gives rise to a characteristic frequency of precession about the direction of the field, resembling the precession of a spinning top. A relatively weak oscillating or rotating magnetic field lying in the plane perpendicular to the static field can, when in synchronism with the precession, radically change the nuclear orientation; this phenomenon is called nuclear magnetic resonance. Such a technique was applied by I. I. Rabi and collaborators to molecular and atomic beams to improve their precision for measuring nuclear magnetic moments and spins. Magnetic resonance can be detected purely electromagnetically, provided the nuclear spins and moments are in some degree preferentially oriented, as they are in normal matter in thermal equilibrium in a static field. As an example one may consider the radio-frequency impedance of a coil of wire wound around a small bottle of ordinary water. If a suitably weak radio-frequency current at 20 megacycles per second is used to measure the impedance, while a strong uniform magnetic field of about 5,000 gauss in the direction perpendicular to the axis of the coil is slowly varied, a measurable increase in resistance will be observed as the field moves through the region of 4,673 gauss. This increase in circuit loss is the result of the magnetic resonance of the hydrogen nuclei in the water. Such effects were first observed by E. M. Purcell and collaborators and, independently, by F. Bloch and collaborators. In this way it has been found possible to study the paramagnetism due to the nuclear moments in matter, a phenomenon that is very difficult to detect statically. Nuclear magnetic resonance has other uses than the precise measurement of the magnetic moments of nuclei. Properties of solids and liquids can be studied because the shapes, widths, splitting and transient responses of the resonances depend upon such properties. Data relating to crystalline structure, thermally induced internal motions, electronic band structures, antiferromagnetism, diamagnetism, electronic paramagnetism, ferroelectricity, self-diffusion in solids and liquids, viscosity in liquids and chemical exchange rates are among the subjects included in the results of experiments on nuclear magnetic resonance. Chemists find the study of the resonance of hydrogen in liquids especially useful because of the presence of small shifts and splittings originating in molecular structure. Nuclei having more than one-half unit of angular moment have magnetic resonances that are profoundly influenced in some materials through torques originating in the electric fields of the atoms and molecules which couple with the nonspherical distribution of electric charge in the nuclei, as characterized by its electric quadrupole moment. It is, for example, possible to have magnetic resonance of such nuclei in some solids at very high frequencies even without a static magnetic field. Studies of such resonances provide further information about electrostatic aspects of solid and nuclear structures. *See* also ATOMIC AND MOLECULAR BEAMS; ELECTRON PARAMAGNETIC RESONANCE.

(R. V. P.)

See E. R. Andrew, *Nuclear Magnetic Resonance* (1955); N. F. Ramsey, *Nuclear Moments* (1953).

NUCLEAR MOMENTS are mechanical, electrical and magnetic quantities related to the rotation of the atomic nucleus and to its shape or configuration. If the nucleus is subjected to electric or magnetic forces arising from nearby atomic electrons, from other nuclei or externally applied fields, the behaviour of the nucleus will depend upon its shape. Since the nucleus is a complicated structure, its electric and magnetic configurations need to be considered separately. By breaking it down into a series of moments of successively decreasing value the complex nuclear shape may be conveniently described as an approximate sum of several simpler structures mutually superimposed. These quantities are of primary importance in understanding the nucleus and the forces that hold the nuclear particles (protons and neutrons) together. Any successful theory of nuclear structure must permit calculations of nuclear moments that agree with experiment. Nuclear electric and magnetic moments have been used extensively to explore the force fields in atoms, molecules, crystals, liquids and laboratory electromagnets.

In the 1920s the existence of nuclear mechanical and magnetic moments was postulated by W. Pauli (and independently by S. A. Goudsmit and E. Back) to explain a very fine splitting (hyperfine structure) of lines in the optical spectra of some atoms. During the early 1930s the development of high-resolution optical spectroscopy and the atomic-beam method made possible rapid advances in this field. Late in the 1930s the introduction of the magnetic-resonance atomic-beam experiment permitted a new order of precision in such investigations. In the years following World War II the techniques of radio-frequency and microwave electronics were applied to magnetic and quadrupole resonance in atoms and molecules. (*See* ATOMIC AND MOLECULAR BEAMS.)

Precision control of radio-frequency radiation as evolved in the 1960s permitted atomic-beam experiments that determine atomic hyperfine interactions to an accuracy exceeding that of any frequency measurement based on time as defined astronomically. The working definition of time, therefore, has been revised in terms of these interactions; such measurements can be made to a precision of 1 part in 1,000,000,000,000.

Definitions.—In physics the term moment refers to the distribution of a quantity with respect to some convenient point or line such as a centre of gravity or an axis of rotation.

The term electric monopole is sometimes used to refer to a point (or uniform spherical) charge distribution. Isolated magnetic monopoles have been sought and, although discussed in the literature, they had not been observed up to the 1960s.

An electric dipole is a combination of a point positive charge and an equal negative charge separated by some distance. The electric dipole moment of such a system is given as charge separation distance multiplied by the charge magnitude (*see* DIPOLE MOMENTS).

A magnetic dipole is exemplified by a magnetic compass needle in which north and south magnetic poles are concentrated at the ends as in fig. 1(A). The magnetic dipole moment of such a system is given as the pole strength multiplied by the needle length. The properties of a magnetic dipole can be approximated by a

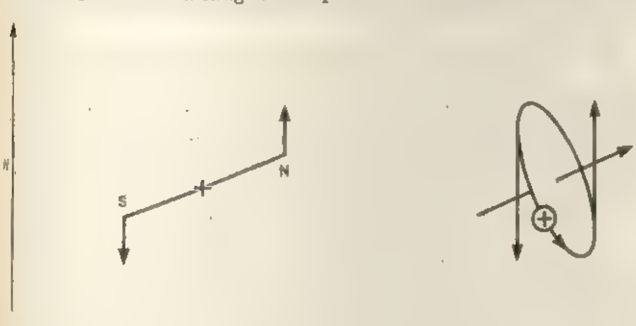

FIG. 1.—MAGNETIC DIPOLE PROPERTIES: (A) MAGNETIC NEEDLE IN THE PRESENCE OF A MAGNETIC FIELD H UNDERGOES FORCES TENDING TO TWIST IT INTO ALIGNMENT WITH THE FIELD; (B) CIRCULAR LOOP OF MOVING POSITIVE CHARGE UNDERGOES SIMILAR FORCES TENDING TO ALIGN THE AXIS PARALLEL TO H

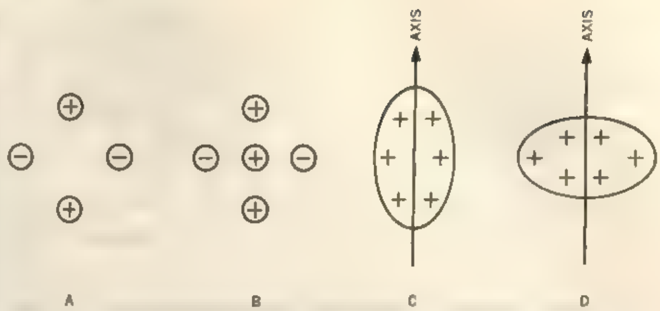

FIG. 2.—ELECTRIC QUADRUPOLE CONFIGURATIONS: (A) IDEALIZED QUADRUPOLE OF TWO OPPOSITELY ORIENTED DIPOLES; (B) SIMILAR QUADRUPOLE WITH AN ADDED MONOPOLE; (C) CONTINUOUS VOLUME OF CHARGE CONSISTING OF A CHARGED PROLATE SPHEROID WITH A POSITIVE MONOPOLE AND A POSITIVE QUADRUPOLE MOMENT; (D) CHARGE DISTRIBUTION CONSISTING OF AN OBLATE SPHEROID AND HAVING A POSITIVE MONOPOLE MOMENT AND A NEGATIVE QUADRUPOLE MOMENT

ring of circulating electric charge as in fig. 1(B) where a disk with a current ring around its circumference is shown. This is equivalent to a magnetic dipole oriented along the axis. In a magnetic field both the magnetic needle and the disk will undergo a twisting force, tending to align their axes parallel to the field.

The nuclear electric quadrupole moment Q is rigorously defined for a nuclear volume τ as $Q = \frac{1}{e} \int_\tau \rho(3z^2 - r^2)d\tau$ where ρ is the charge density, z is the co-ordinate along the axis of reference, r is the radius vector to the volume element $d\tau$ and e is the electronic charge.

It is possible to build up charge or current distributions which will have a quadrupole (four-pole) moment that can be formed as shown in fig. 2(A). Such a configuration could have zero mono-

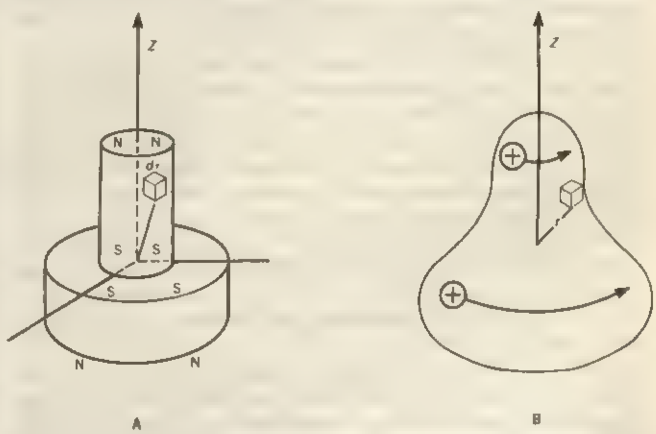

FIG. 3.—MAGNETIC OCTUPOLE CONFIGURATIONS: (A) ARRAY OF DIPOLES OVER A VOLUME WHICH COULD HAVE A TOTAL DIPOLE MOMENT OF ZERO AND AN APPRECIABLE OCTUPOLE MOMENT; (B) CONTINUOUS DISTRIBUTION OF CIRCULATING POSITIVE CHARGE WHICH COULD HAVE POSITIVE DIPOLE AND OCTUPOLE MOMENTS

pole and dipole moments but a positive quadrupole moment. Other examples of charge distributions with quadrupole moments are illustrated in the figure.

A nuclear magnetic octupole moment Ω may be defined mathematically as $\Omega = \int_\tau \frac{1}{2}(5z^3 - 3zr^2)\ \nabla \cdot M d\tau$ where z, r and τ are defined as for the quadrupole moment and $\nabla \cdot M$ is the divergence of the nuclear magnetization. The quantity $\nabla \cdot M$ may be imagined as the equivalent pole density at the ends of a dipole. Thus an array of magnetic dipoles as illustrated in fig. 3(A) might have zero dipole moment but an octupole moment greater than zero. A distribution of circulating positive charge illustrated in fig. 3(B) would have both magnetic dipole and octupole moments. There is no a priori reason for excluding electric 16-pole moments from atomic nuclei but none had been observed up to the 1960s.

The spin (moment of momentum, or angular momentum) of a particle with mass m as in fig. 4(A), moving at velocity v with respect to a centre O is given as mvr where r is the distance from m to the line of motion (*see* MECHANICS).

FIG. 4.—SPIN (MOMENT OF MOMENTUM, ANGULAR MOMENTUM): (A) THE SPIN WITH RESPECT TO CENTRE O OF A PARTICLE OF MASS m WITH VELOCITY v IS GIVEN AS mvr; (B) A ROTATING RIGID BODY CAN BE IMAGINED AS COMPOSED OF MANY PARTICLES. THE TOTAL SPIN IS THE SUM $m_1v_1r_1 + m_2v_2r_2 + \ldots$

A rigid body, as in fig. 4(B) may be considered as composed of many particles $m_1, m_2, m_3, \ldots$ Such a body can be viewed at any instant as though each particle were moving at right angles to its radius from 0. The sum of angular momenta of all mass particles is termed the angular momentum (or spin) of the entire rigid body. Since angular momentum refers to a particular direction and sense of rotation it is a vector quantity, and can be represented by a line (in the direction of the axis of rotation) with length proportional to the magnitude of the quantity. A positive sense to the line is arbitrarily taken such that when one looks in that direction the rotation appears clockwise.

Since the rotation of the nuclear particles in their orbits is rapid compared to the time taken for most experimental observations the nuclear shape appears to be symmetrical about the axis of rotation. As a consequence of this and of certain other symmetry properties of forces between particles in the nucleus, nuclei are not expected to have electric dipole or octupole moments, or magnetic monopole, quadrupole or 16-pole moments.

Quantum Effects.—The laws of mechanics (*see* QUANTUM MECHANICS) that describe the motions of atomic or nuclear particles are somewhat different from those of classical mechanics. For example, in classical mechanics a rotating body can have any given amount of angular momentum. An atomic system of a particle in orbit, according to the simplified quantum mechanics, can have only some whole number of units or quanta, equal to $h/2\pi$, where h is Planck's constant (6.625×10^{-27} erg sec.). In addition to its orbital motion each proton and neutron spins about its own axis, just as the earth does while at the same time revolving about the sun. The angular momentum associated with each particle spin is always $\frac{1}{2}$ unit.

An additional aspect of angular momentum in quantum mechanics is that the axis of rotation cannot be randomly oriented. In space there must be at least some small magnetic field present at all times. With respect to this field, the angular momentum vector can be oriented only in those directions such that its possible projections along the field differ by whole units of $h/2\pi$. For example, if the total angular momentum is 3 units, then the possible projections along the field can be 3, 2, 1, 0, −1, −2 and −3 (*see* fig. 5). These values of the projections are designated by the symbol m and are termed the magnetic quantum numbers. (More accurately the discrete values of orbital angular momentum are $\sqrt{l(l+1)}$ where the quantum number $l = 1, 2, 3, \ldots$ Similarly, the spin quantum number s determines the magnitude of spin equal to $\sqrt{s(s+1)}$. These quantities approximate the simplified integral values for large quantum numbers. The statements regarding integral values of m are still exact.)

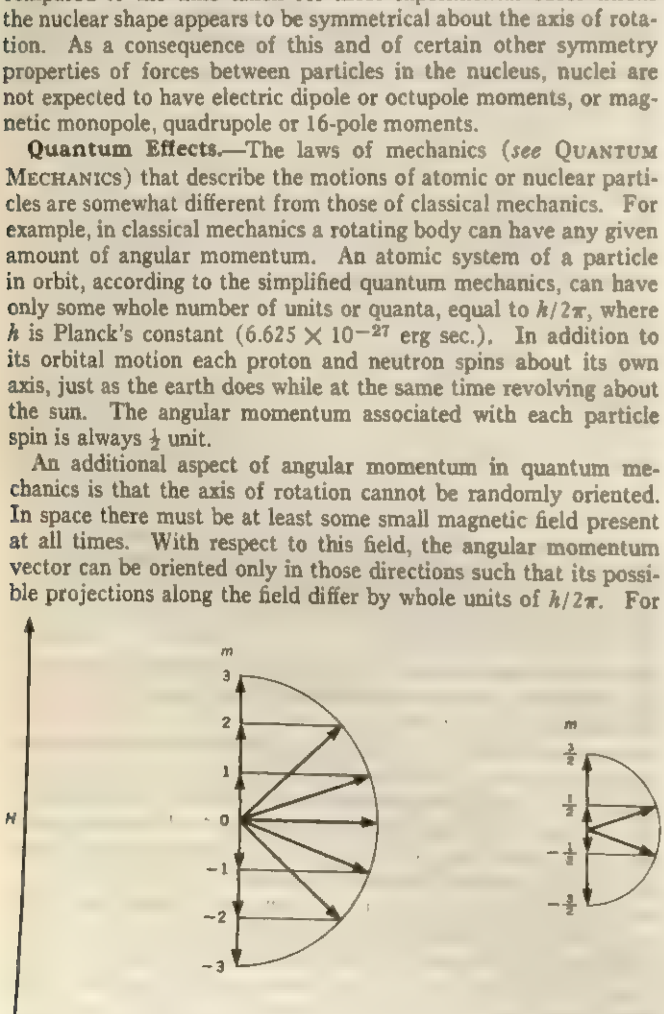

FIG. 5.—POSSIBLE ORIENTATIONS OF ANGULAR MOMENTUM VECTOR: (A) IN THE PRESENCE OF A MAGNETIC FIELD H A VECTOR OF 3 UNITS HAS POSSIBLE PROJECTIONS m OF VALUE 3, 2, 1, 0, −1, −2 AND −3; (B) A VECTOR OF $\frac{3}{2}$ UNITS HAS POSSIBLE PROJECTIONS OF $\frac{3}{2}$, $\frac{1}{2}$, $-\frac{1}{2}$ AND $-\frac{3}{2}$

One consequence of the orientation aspect of angular momentum is that the total angular momentum of the nucleus is a vector sum of the components (orbital plus particle spin) giving an integral number of units if there are an even number of particles or an integral number plus $\frac{1}{2}$ unit if there are an odd number of particles.

Interactions Involving Moments.—Consider first the magnetic dipole interaction. Since a uniform field exerts a force on a dipole tending to align it with the field, any other orientation will represent a state of higher potential energy. This difference in energy will be expressed by $\Delta W_m = \frac{\mu}{I} mH$ where I is the total angular momentum, μ is the magnetic dipole moment, H is the applied magnetic field, and m is the magnetic quantum number; ΔW_m represents the work done to orient the system from the lowest m-state to that of next higher energy. It is a primary concept in quantum mechanics that an atomic system can generally exist only in discrete energy states, and to jump from one to the other it must emit or absorb radiant energy depending on whether the initial state E_1 is higher or lower than the final state E_2. The radiant energy will have a frequency ν given by $E_1 - E_2 = h\nu$ where h is Planck's constant.

Suppose a system of nuclei is given in which the nuclear spins are all oriented in the m-state of lowest energy. If these nuclei are subjected to electromagnetic radiation with a frequency of exactly ν the radiant energy will be absorbed and the system will jump to the next higher m-state. Under appropriate conditions this energy absorption can be detected electronically and the frequency ν measured with extreme precision; thus the energy difference can be determined with great accuracy. These principles form the basis of the techniques of magnetic resonance and may be applied to solids, liquids, gases in bulk, and to free atoms in an atomic beam (*see* NUCLEAR MAGNETIC RESONANCE).

If the atomic electrons have a combined angular momentum of one or more units they will produce an electric field at the nucleus which can interact with a nuclear electric quadrupole moment. If the electronic angular momentum is $\frac{3}{2}$ units or more, there will be a magnetic field that can interact with a nuclear magnetic octupole moment.

In general the quadrupole effects are small compared with those of the dipoles, serving to produce a slight shift in the position of the energy levels as expected from dipoles alone. Magnetic octupole moments produce extremely small additional shifts that require extremely high precision in measurement and have been observed in only a few cases.

An atom with a magnetic dipole moment exposed to a nonuniform magnetic field undergoes a linear force in addition to its tendency toward orientation. The various m substates of fig. 5 are acted upon by different forces. The use of an atomic beam makes possible the physical separation of these states and an observation of an induced transition between them. In this way the energy difference between substates is observed directly.

The atomic- or molecular-beam technique has been applied to many problems involving nuclear moment interactions and has given results that are among the most precise physical measurements ever made. The method has permitted verification of the basic ideas involved in understanding the properties of nuclear moments. This method has also permitted the measurement of more than 150 nuclear spins.

Other principal techniques for measuring nuclear moments are magnetic resonance, optical spectroscopy, microwave spectroscopy,

electron paramagnetic resonance and pure electric quadrupole resonance (*see* SPECTROSCOPY: *Applications*; ELECTRON PARAMAGNETIC RESONANCE; RESONANCE ENERGIES).

Empirical Results of Measurements.—As a result of the measurement of spin for more than 150 different nuclei in their most stable state the following empirical rules have been found to hold: (1) nuclei with an odd number of particles have spins of $(m+\frac{1}{2})$ units of $h/2\pi$ where m is an integer; (2) nuclei with an even number of particles have spins of m units of $h/2\pi$; (3) nuclei with an even number of protons and an even number of neutrons have zero spins.

These regularities form the starting point of the shell model theory of nuclear structure which has been so fruitful in predicting nuclear properties that M. G. Mayer and J. H. D. Jensen (*qq.v.*) were awarded Nobel prizes in 1963 for their role in its development (*see* NUCLEUS: *Nuclear Structure and Nuclear Forces*). The values of nuclear spin range from 0 to 12 units of $h/2\pi$. Measured values of nuclear magnetic dipole moments range from 0.002 in thallium-198 to more than 6 nuclear magneton units in neptunium-237. (The nuclear magneton is defined as $eh/4\pi Mc = 0.505038 \times 10^{-23}$ erg/gauss where e is the electronic charge, M is the mass of the proton, h is Planck's constant and c is the velocity of light.) Values of nuclear moments are given in some of the references cited below, but most extensively in the nuclear data tables published by the National Research council of the U.S. National Academy of Sciences.

As a result of the nature of nuclear forces one would expect the following relationship between nuclear spin and highest electric or magnetic moment associated with the nucleus:

spin 0	electric monopole
spin $\frac{1}{2}$	magnetic dipole
spin 1	electric quadrupole
spin $\frac{3}{2}$	magnetic octupole
spin 2	electric 16-pole, etc.

There appears to be no evidence in conflict with these predictions.

NUCLEAR PHYSICS: *see* ACCELERATORS, PARTICLE; ATOM; ATOMIC ENERGY; NUCLEUS; PARTICLES, ELEMENTARY.

NUCLEIC ACIDS, a group of large, complex compounds of high molecular weight that occur in all plant and animal cells and viruses and are of great importance since they control the formation of proteins in the cells and also take part in the transmission of heredity information (the genetic code). Upon mild hydrolysis nucleic acids yield (1) the ortho (trihydrate) form of phosphoric acid; (2) a pentose (five-carbon) sugar or a deoxypentose (a pentose with one oxygen atom removed) sugar; and (3) a mixture of nitrogenous bases (*see* fig. 1) of the pyrimidine and purine types. Pyrimidines, also called 1,3-diazines, are six-membered rings that contain nitrogen atoms in the 1 and 3 positions. Purines (*q.v.*) contain two rings, one a pyrimidine and the other an imidazole (*i.e.*, a five-membered ring with nitrogen atoms in the 7 and 9 positions).

Structure.—Nucleic acids fall into two chemically distinct classes:

1. In ribonucleic acids (commonly abbreviated to RNAs) the sugar is a pentose and the principal bases are the purines adenine and guanine and the pyrimidines cytosine and uracil. Small amounts of thymine and of methylated adenine, guanine and cytosine have also been reported, especially in the "soluble RNA" (sRNA) of the cell cytoplasm (*see* below).

2. In deoxyribonucleic acids (commonly abbreviated to DNAs) the sugar is a deoxypentose and the principal bases are the purines adenine and guanine and the pyrimidines cytosine and thymine. In the DNA of certain bacterial viruses cytosine is absent and its place is taken by 5-hydroxymethylcytosine, which is frequently substituted in the 5-hydroxymethyl group with one or two glucose residues. Small quantities of 5-methylcytosine have also been found, especially in the DNA of wheat germ.

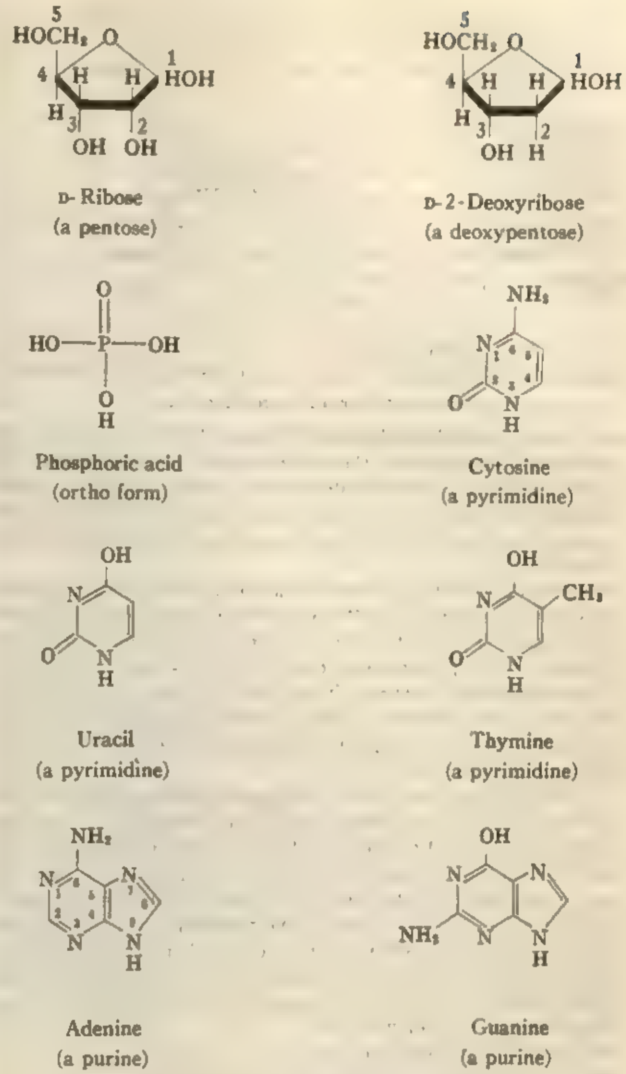

FIG. 1.—MAJOR COMPONENTS OF NUCLEIC ACIDS

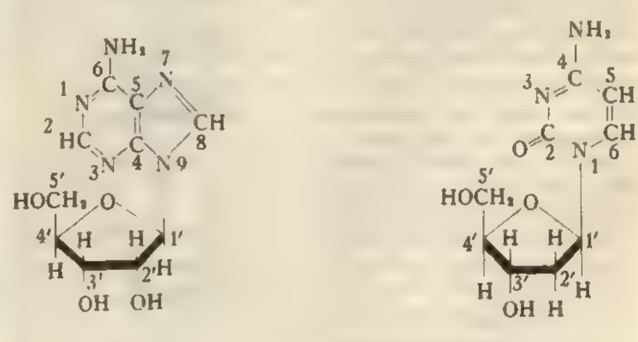
In all cases in which the question has been investigated the pentose of RNA has been identified as D-ribose and the deoxypentose of DNA as D-2-deoxyribose. In both RNA and DNA the fundamental structural unit is the nucleotide, in which a purine or pyrimidine base is linked to a sugar molecule, which in turn is esterified with orthophosphate. Normally the nitrogen atom at position 9 of the purine or position 1 of the pyrimidine is linked to the carbon at position 1 of the sugar. The base-sugar subunit compound is termed a nucleoside and is named after the base. Thus the ribonucleosides of adenine, guanine, cytosine and uracil are called adenosine (*see* fig. 2), guanosine, cytidine and uridine, respectively. The deoxyribonucleoside of thymine is called thymi-



Adenosine Deoxycytidine

3'-Adenylic acid (Adenosine-3'-phosphate)

5'-Thymidylic acid (Thymidine-5'-phosphate)

FIG. 3.—EXAMPLES OF NUCLEOTIDES

dine; other deoxyribonucleosides are named by adding the prefix "deoxy-" to the names of the corresponding ribonucleosides. In pseudo-uridine, a ribonucleoside found in small quantities in RNA (especially sRNA, *see* below), the base-sugar linkage involves the carbon at position 5 of the uracil instead of the nitrogen at position 1.

Nucleotides (*see* fig. 3) may be named as acids or as phosphate esters of nucleosides (*e.g.*, 3'-adenylic acid, or adenosine-3'-phosphate; and 5'-thymidylic acid, or thymidine-5'-phosphate). In naturally occurring nucleotides the phosphate is usually at position 5 of the sugar but sometimes it occurs at position 3 and occasionally is attached cyclically to both. Free mononucleotides of this sort form an important part of the chemical machinery of the cells, especially as coenzymes.

Nucleic acid molecules can be regarded as polynucleotides that are built up from 5'-nucleotide units, the phosphate of each nucleotide being linked to the 3' hydroxyl of the succeeding nucleotide. The resulting molecule consists of a long chain in which sugar and phosphate alternate and in which a base is attached to each sugar (*see* fig. 4). The relative proportions of the different bases vary from one RNA or DNA to another depending on the sources from which they are isolated. But as a general rule the number of bases with a 6-amino group (*i.e.*, adenine and cytosine) is equal to the number with a 6-keto group (*i.e.*, guanine and thymine or uracil). It was not possible in the early 1960s to determine the sequence of bases throughout the length of an RNA or DNA molecule, but the available evidence made it highly unlikely that they were arranged in any regular repeating pattern.

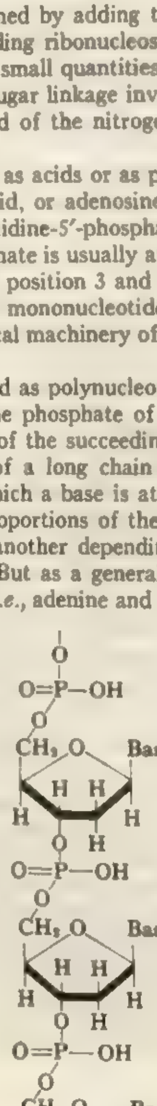

FIG. 4.—STRUCTURE OF THE POLYNUCLEOTIDE CHAIN IN DNA

Molecular Weight.—The molecular weight of DNA or RNA depends on the source from which it is obtained and the method by which it is isolated. The values obtained for DNA in the early 1960s fell mostly in the range 1,000,000–10,000,000, but there was some evidence that in vivo the true molecular weight might be of the order of 100,000,000 and that the mechanical shearing forces to which such an enormous molecule was subjected during even the mildest isolation procedure might degrade it. Estimates of the molecular weight of ribosomal RNA (*see* below) were of the order of 1,000,000. On the other hand, sRNA (*see* below) had a molecular weight of only about 25,000.

Occurrence.—All nucleated plant and animal cells and all microorganisms other than viruses contain both types of nucleic acid. In general, plant viruses contain RNA and most bacterial viruses DNA. Animal viruses may contain either RNA (*e.g.*, poliomyelitis virus) or DNA (*e.g.*, vaccinia virus).

As their name implies, nucleic acids were originally isolated from cell nuclei, and for many years it was assumed that they were not found elsewhere. This view was not seriously challenged until about 1940, when two new techniques were devised for investigating the structural elements of the cell.

The first of these was histochemical. Because of their content of purines and pyrimidines, nucleic acids absorb ultraviolet light very intensely at a wave length of about 260 mμ. Consequently if a histological tissue section is photographed in ultraviolet light of about this wave length (using a microscope with quartz lenses) the parts of the section that have a high concentration of nucleic acids can be identified as dark areas in the photograph. This method does not distinguish between DNA and RNA but this distinction can be made by using specific histochemical reactions.

The results obtained by these methods may be summarized as follows: All cell nuclei contain DNA and except in a few special cases DNA is not found outside the nucleus. During cell division DNA is found only in the chromosomes. Most of the RNA of the cell is found in the cytoplasm but a small proportion can be demonstrated in the nucleus, especially in the nucleolus.

The second main technique for elucidating the chemistry of cell structure has been the isolation of cell components such as nuclei and mitochondria in sufficiently large amounts to allow them to be subjected to chemical analysis. The principle of the method is to break up cells mechanically (or by ultrasonic vibration) in an aqueous or (more rarely) an organic solvent. The resulting suspension of cell debris is then sedimented in the centrifuge. By varying such conditions as the density of the medium and the speed of the centrifuge it is possible not only to isolate the cell nuclei in bulk but also to separate the cytoplasmic debris into several fractions that can, by electron microscopy, be identified with particular structures in the intact cell. This technique has been applied successfully to a variety of plant and animal tissues and to microorganisms. Analysis of fractions isolated in bulk in this manner has confirmed that DNA is found only in the nuclei, which also contain a small amount of RNA. The bulk of the RNA (80%–90%) is found combined with protein in the ribosomes. The ribosomes, which are granules dense to electrons and measuring 10 to 20 mμ in diameter, are found attached to the endoplasmic reticulum in the intact cell. A lesser amount of RNA (the so-called sRNA) is found free in solution in the cell sap. The RNA content of the mitochondria is almost negligible.
